Canadian Representatives:

FRICK ICE & REFRIGERATING COMPANY

Montreal, Canada

There is a FRICK Machine for every refrigerating purpose—all types—Vertical — Horizontal — Absorption.

The VILTER MANUFACTURING CO.

Manufacturers of

ICE MAKING and REFRIGERATING MACHINERY, CORLISS and POPPET VALVE ENGINES, ETC.

242 Beecher Street, Milwaukee, Wisconsin, U. S. A.

Branch Offices:

New York, N.Y.	Philadelphia, Pa.
Pittsburgh, Pa.	Chicago, Ill.
St. Louis, Mo.	Kansas City, Mo.
Houston, Texas.	Los Angeles, Cal.
Salt Lake City, Utah.	Seattle, Wash.
Wellington, New Zealand.	

Products

Vilter Rolling Mill and Girder Corliss Engines, Poppet Valve Engines, Ice Making and Refrigerating Machinery. Machinery for Breweries and Bottlers, Special Machinery.

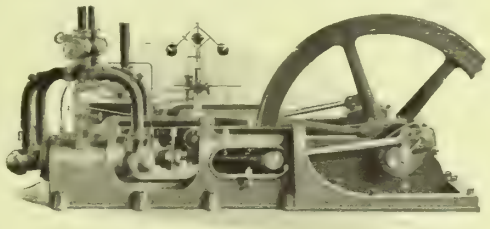
Vilter Improved Poppet Valve Steam Engine

Vilter Poppet Valve Engines effect real power plant economy. We know our statement will be attested to by owners and operating engineers of the plants where Vilter Poppet Valve Engines have been installed. Your request for proof need entail no obligations to purchase.

Vilter Tandem Poppet Valve Engine, direct connected to a Vilter Ammonia Compressor.

Vilter Rolling Mill Type Ammonia Compressor

The Rolling Mill Type Compressor is built along very heavy lines and for all conditions of service. It is used only with slight modifications in all sizes of compressors. The general design is very pleasing to the eye, the machine making an artistic asset to any engine-room. Its very appearance gives assurance and proof of its strength and reliability. This type is built in sizes from 6 Tons to 25 Tons daily refrigerating capacity.



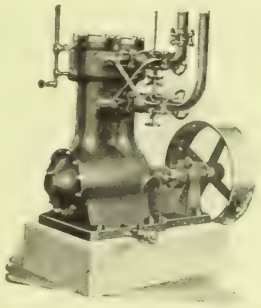
Rolling Mill Type Compressor.

Vilter Duplex Heavy Duty Ammonia Compressors

A Duplex steam-driven unit, with horizontal double-acting ammonia compressors and direct connected to Cross Compound Corliss Engine. Compressor equipped with multiple valve heads, giving maximum area. Stuffing box of the double-packed type, with oil seal and pressure release. The duplex type is built in sizes from 125 to 750 tons.

Small Vertical Twin Cylinder Ammonia Compressor

A small, single-acting compressor, especially designed for users of comparatively small quantities of refrigeration. It is reasonable in first cost. Economical to operate. Simple in construction. Needs very little attention. Is always ready for service. Built in sizes from 1 ton to 20 tons daily refrigerating capacity.



Vertical Twin Cylinder Refrigerating Machine.

Vilter Rolling Mill Type Corliss Engine

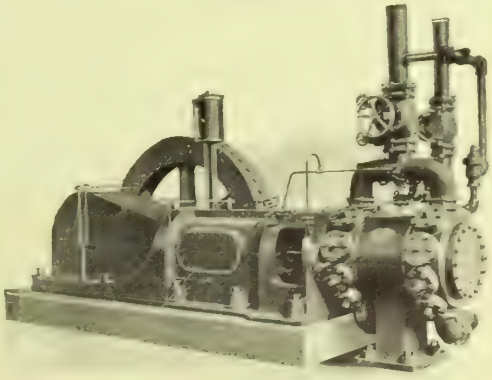
The Rolling Mill type Corliss Engine is of exceptionally massive construction throughout, and is adapted to any class of service from the steady belted load to the direct connected electrical service, in which the engine is subjected to heavy and extremely variable loads. It is built for high steam pressures and high rotative speeds, and may be used with superheated steam up to 100° F. superheat.

Vilter Girder Frame Corliss Engine

is exceedingly strong and rigid, and is designed to take shocks and overloads without possibility of misalignment. Made in 26 sizes, from 25 h.p. up.

Vilter High Speed Ammonia Compressor

Vilter horizontal high speed ammonia compressors are simple in design; rugged in appearance, and in the character of service they give. They are specially designed for direct connection to the newest types of high-speed prime movers, and particularly adapted for direct connection to synchronous motors, a method of drive which is proving so highly economical and efficient.



Horizontal High Speed Ammonia Compressor.

An Ice Storage Made This Possible

A 5,000-ton ice storage thoroughly insulated with Nonpareil Corkboard City Ice Company, Lexington, Ky.

If you can sell more ice than you can produce during the summer months, why not avail yourself of the fund of information, relative to the economic advantage of ice storages which we have collected in the course of fifteen years in the insulation business. All of these data are at your command.

Due to the seasonable demand for ice, the City Ice Company, Lexington, Ky., prior to 1912, worked at full capacity during the summer months, but had little or no load during the slack season. As a result, in 1911, their output was only 43.9% of their yearly capacity, and the manufacturing cost averaged $2.50 per ton.

To relieve this condition, in 1912 they installed some new equipment, and an 1800-ton ice storage house, thoroughly insulated with Nonpareil Corkboard Insulation. By filling this storage house in the off-season, their output was increased to 63.9% of their yearly capacity, and the manufacturing cost was reduced to 42 cents per ton.

But this increased production did not take care of the market and in 1914 the storage capacity was enlarged to 5,000 tons. Now the City Ice Company operate under a nearly constant load the year 'round. The efficiency of the employees has increased materially because of constant employment. And in 1915 the Company manufactured and sold 91.3% and 91.2% respectively, of the total yearly capacity.

Armstrong Cork and Insulation Company, Limited 11 Church St., Toronto, Ontario, Canada 505 McGill Bldg., Montreal, Quebec, Canada

Also manufacturers of Nonpareil Cork Covering for brine, ammonia and ice water lines; Nonpareil Insulating Brick for boiler settings, etc.; Circle A Cork Brick for cold storage room floors; Nonpareil High Pressure Covering for steam lines; Nonpareil Cork Machinery Isolation for deadening the noises of machines; and Linotile for floors in offices, residences, etc.

NONPAREIL CORKBOARD INSULATION

For Ice Storage and Cold Storage Rooms

Electric Power Plant For Sale

IT IS COMPOSED OF THE FOLLOWING:

2—13 x 14 Robb & Armstrong S.C. Engines.

2—4 in. Robb Steam Separators.

2—Allis-Chalmers 75 Kw., 275 R.P.M., 240 volt type 1 Generators, and one Switch Board.

This plant is practically in as good shape as when it was installed. Open for inspection by giving us two days' notice.

An Idea or Two for Engineers

John Hale says
If Canadian engineers
Would use the pages
Of POWER HOUSE
To exchange their ideas
They would not only benefit others
But they would help
Themselves.

* * *

You have a dollar,
I have a dollar
And we swap,
You have my dollar and I have yours
We are no better off.
But if you have an idea
And I have an idea and we swap,
We each have two instead of one.

* * *

You have an engineering idea,
We have an engineering paper.
You send us your idea and
We publish it.

You're extending a helping hand
To some poor chap
Who may be up against it—
Stuck for want of your idea.

* * *

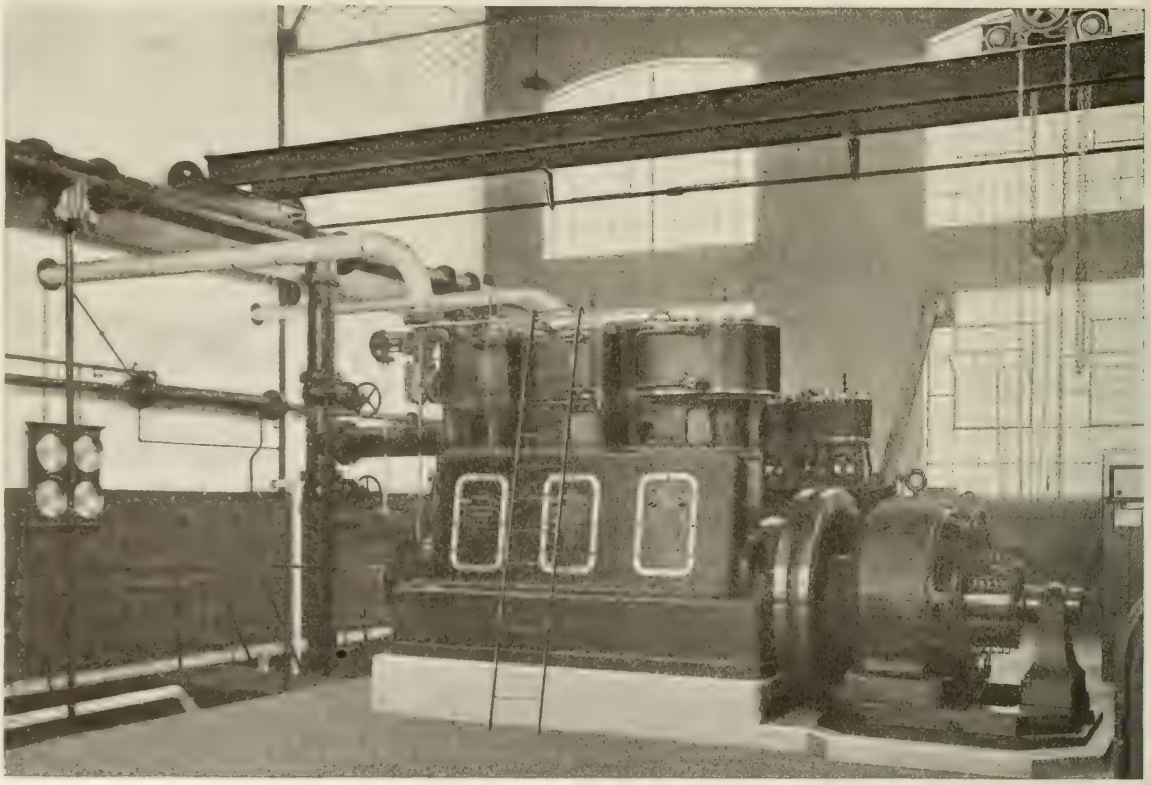
We'll pay you for your idea
And if other engineers follow your
Example, you're going to get a lot
Of good ideas yourself.
The whole business of engineering
Will have fewer thorns
And more roses
And rises.

* * *

You're going through life
Just once
And we have an idea
That if you use your ideas
To help others in this world
You'll be happy in the next,
Which seems to us
Well worth considering.

POWER EQUIPMENT

Built to Meet Your Own Requirements



A corner in the Engine Room of our New Power Plant recently erected at our Main South Works. Equipped with G. & McC. Co. Three-Cylinder Compound and Two-Cylinder Compound Vertical Forced Lubrication Steam Engines.

G. & McC. CO. ENGINES and BOILERS

will provide your plant with

A Continuous and Economical Service

WE BUILD

Horizontal and Vertical Steam Engines; Steam Turbines; Return Tubular and Water Tube Boilers; Heaters; Tanks; Pumps and Condensers; Transmission Machinery; Safes, Vaults and Vault Doors.

The advice of our Engineering Experts, our Catalogues, Specifications, Photographs, etc., will be cheerfully supplied to interested parties.

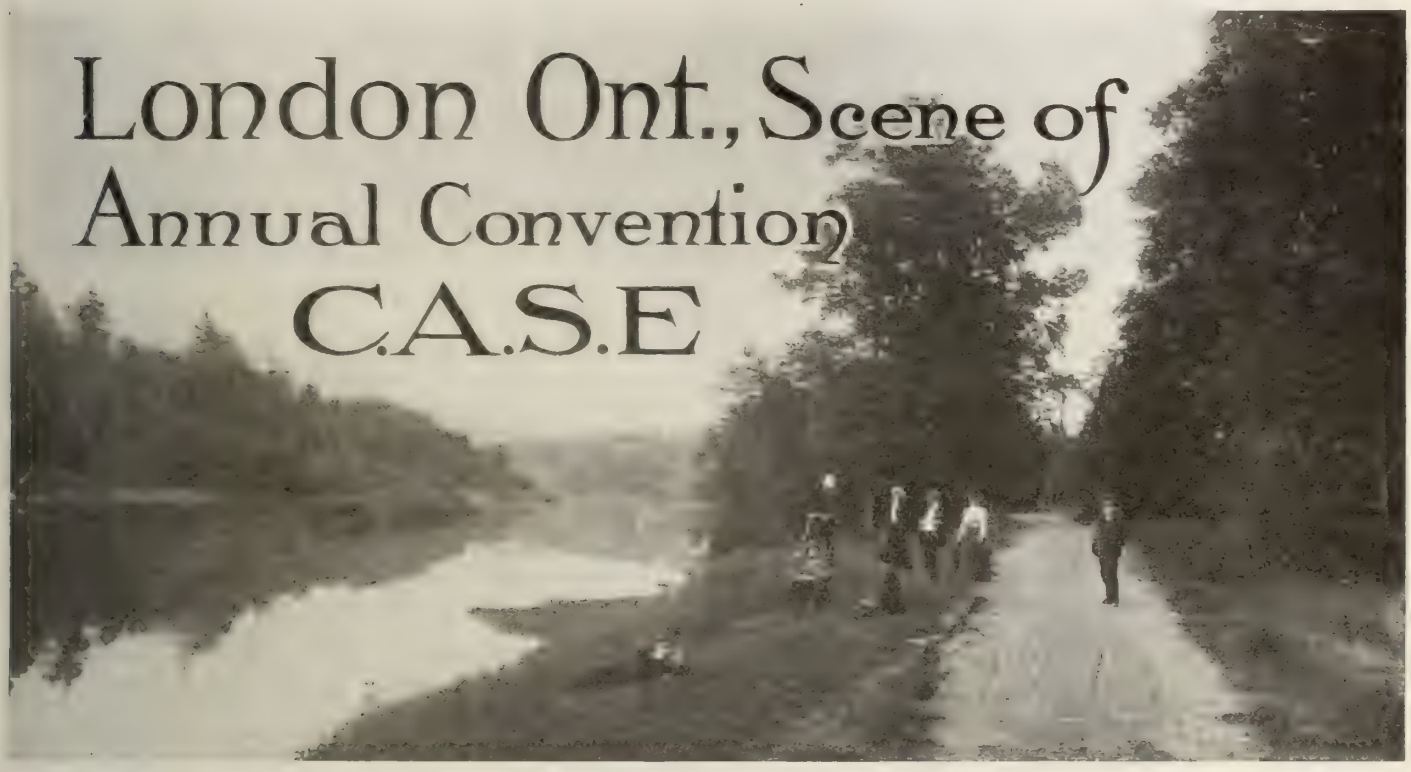
POWER HOUSE

London Ont., Scene of Annual Convention C.A.S.E



ON THE BANKS OF THE THAMES RIVER. SPRINGBANK PUMPING STATION IN THE MIDDLE BACKGROUND.

THE Canadian Association of Stationary Engineers has selected a good centre for its 1918 convention. London has seen many conventions, and it will see others. Especially at this time of year, when the great outdoors bids strongly for one's time. London has charms that few places can boast. Parks in abundance, wide streets lined with great shade trees, well-kept homes and grounds, a quick run on the electrics to Port Stanley. In fact, there is just enough outdoor attraction to provide relaxation and pleasure for the delegates, and not enough to make the convention and its purposes of secondary consideration.

London itelf has an interesting history and an historic name. It is a splendid distributing centre, surrounded by a good agricultural and mixed farming district. It is not, and never has been, a boom town. London's growth has been gradual but sure; but London can stand hard times, and perhaps after all that's the acid test of real stability. People who live in London like the place—those who leave carry with them pleasant memories of happy days and worth-while friendships. Yes. it's a good sample of the best that Canada has to offer in the way of the city that has not attained to metropolitan size. It retains the desirable traits of the large town and at the same time takes in every advantage of the larger centres.

The History of London

It will no doubt be of interest to readers of POWER HOUSE, and especially those who attend the Stationary Engineers' Convention, to read of London's early history, its development and growth, and the particular traits that have steadily brought it to the front, and enabled it to keep pace with the development of other places in Ontario and the Dominion.

Should a person desire to do so, it is quite possible to start the picture of London's early history in the woods.

Ninety Years Ago

Ninety years ago "The Forks," as the site of the city was then known (owing to the junction at that point of the north and south branches of the River Thames), was one vast wilderness, the haunt of the bear and the wolf, and the hunting ground of the red man. As far back as 1792, Governor Simcoe had visited the spot—which has been described as "a beautiful situation formed by a bend of the river, a grove of hemlock and pine, and a large creek"—and was so charmed with it that he announced his intention of making it the capital of the new colony of Upper Canada.

It was not, however, until the year 1826 that the site of the future city was surveyed, the first clearance in the woods made, and the first log house built. By the following year the population had grown to 133 persons, and London having meanwhile been chosen as the judicial headquarters of the district, added importance was given the place by the erection of a court-house, which was at that time the most imposing structure to be seen within a hundred miles or more.

In 1838 the place was created a municipality, and two years later, with a population of 2,000 was made a village. In 1845, the population being then 3,500, London suffered a serious setback in being visited by what has since been known as "the great fire," which destroyed a large number of its best buildings. But it rapidly recovered from the effects of the conflagration, for three years later we find it incorporated as a town, with a population of 4,668. That year (1848) also saw the establishment of public schools in London; and it might be remarked, in passing, that in no particular has London kept better pace with other Canadian cities than in the matter of education. The first decennial census, published in 1852, showed the population to have jumped to over 7,000, and two years later a population of 10,060 brought incorporation as a city.

WESTERN UNIVERSITY, A NOTED CENTRE OF LEARNING IN WESTERN ONTARIO.

Growth of Population

It will be seen there was little of the "boom" or the leaps-and-bounds about London's growth; rather it was of the steady, substantial and come-to-stay character. Such, indeed, has also been the growth of population from the time of incorporation up to the present; it has been increased every year, not one instance of decline being recorded. Official figures obtainable give an idea of the steady rise of population during the past fifty-seven years: 1860, 11,200; 1864, 11,555; 1871, 15,826; 1877, 19,100; 1881, 19,725; 1885, 26,075; 1890, 30,075; 1891, 31,977; 1898, 38,224; 1906, 44,704, while the latest figures credit London with 60,000 people.

All this time populous suburbs had been growing to the east, south and west of the city. It was felt that it would be to the interest of all concerned if these outlying sections, two of which had been formed into independent municipalities, were brought into and made to form part of the city. Accordingly, steps were taken to bring this about, the result being the annexation of London East in 1885, of London South in 1890, and London West in 1898.

As a Railway Centre

While a great deal of agitation and misionary work had been done all over Ontario regarding the Hydro radial plans, it remained for London to be the centre at which the first railway, converted from steam power to electric, would open for traffic. It was a gala day for London and for the Hydro group in Ontario when the opening excursion left that city for Port Stanley over the best-built and equipped electric road there is in the country. Delegates were present from all sections of the province, and engineers were there from many points to see what manner of thing this Hydro radial line was. It gave to all a good idea of the goal toward which the Hydro policy was driving.

London is a good railway centre. It was in October, 1853—nearly fifty-four years ago—that the first train on the Great Western Railway arrived in London from the east, which road shortly afterwards was continued through to Detroit. Up to that time all transportation to neighboring towns and to the lakes was by horse and wagon, so that the advent of the "iron horse" was an event of no mean importance. This had the effect of spurring on the enterprising Londoners of that day in the construction of a railway to Port Stanley, lying on the shores of Lake Erie, twenty-three miles distant, and the year 1856 saw the compleltion of that road.

In the year following the city was connected with the G. T. R. main line by the completion of a spur from St. Mary's. The London, Huron & Bruce was the next railway enterprise undertaken by the citizens, and as it would open up direct communication with the thriving towns to the north of the city, the Great Western Railway Company were easily induced to take over the construction of the line, the result being its completion in 1870. With the subsequent absorption of the G.W.R. by the G.T.R., all these lines passed under one management. The construction of the Canada Southern Railway from Niagara Falls to Detroit, and of the Air Line from the Falls to Glencoe, there connecting with the Grand Trunk's line to Detroit, was a matter of no little importance to London. The subsequent construction of the Lake Erie & Detroit River Railway, now part of the Pere Marquette system, gave London still another outlet. The construction some years ago of the branch of the Canadian Pacific Railway through London to Detroit placed the city in direct connection with the great transcontinental road, and thus completed a network of railways in Western Ontario, of which London is the centre.

The first Hydro trunk line, votes for which had been passed by the municipalities concerned, will be Toronto to London, by way of Guelph and Stratford.

ONE OF THE MANY BEAUTIFUL STREETS FOR WHICH LONDON IS FAMOUS.

Its Development

Tables of figures are often dry reading matter. They lack snap and are usually associated with blue books and other documents that are referred to from pressure rather than preference or desire. But figures often tell a pretty good story. For instance if a man tells you he's worth a million to-day, and you knew he had nothing two weeks ago, the figures would suggest quite a story. Well, it's the same regarding London's figures about growth and development. Post office revenue, for instance, is a pretty fair index. The figures for London show:—

1910	$145,250
1911	155,097
1912	170,620
1913	181,185
1914	202,986
1915	221,911
1916	298,917

Customs Receipts

Customs receipts also give a very accurate idea of the power of the people to buy. London's figures are:—

1908	$ 783,208
1911	1,017,503
1914	1,088,078
1915	1,100,711
1916	1,569,311

Bank Clearings

1903	$ 42,848,577
1906	58,063,826
1909	62,093,337
1912	84,525,961
1914	86,024,236
1915	89,774,787
1917	100,900,560

Building Permits

As a general thing there has been very little building going on since the start of the war. Material has been high, labor has been scarce, and the pressing needs of national finance have had first call on the money in the hands of the people. But London has done well even in the war years. The development in recent years is shown by the following:—

1910	$ 805,094
1911	1,036,989
1912	1,136,108
1913	1,789,920
1914	1,837,735
1915	1,207,630
1916	926,125
1917 (11 mon.)	833,210

Since the war started in August of 1914 London has erected almost a thousand dwellings at a cost of well on to two million dollars.

Over 30 factories and warehouses, or additions at a cost of well over half a million.

Over 40 stores, office buildings or places of amusement, costing over half a million.

The building of schools has also been keeping pace with the needs of the population, eight of these erected in recent years costing $460,000.

INTERSECTION OF DUNDAS AND RICHMOND STREETS. LONDON'S THOROUGHFARES ARE COSMOPOLITAN IN THEIR VARIETY.

As a Labor Centre

London is justly celebrated for the quantity and quality of its labor. A large percentage—estimated at 80 per cent.—of the industrial workers own their homes, a fact which indicates agreeable living conditions. Serious labor troubles are practically unknown, and the variety

VIEW IN SPRINGBANK PARK. PROFUSE FOLIAGE AND FLOWERS MAKE THE CITY'S SURROUNDINGS IDEAL.

of occupations which the established factories afford provides a supply of skilled labor of almost every kind. London's factories, covering some 75 distinct lines of manufacture, number over 250, and employ in the aggregate upwards of 12,000 people. Among the leading industries are over a dozen firms engaged in the manufacture of cigars. Montreal alone exceeds London's cigar output.

Here also is the largest stove works in the British Empire, the McClary Mfg. Co., employing 1,500 men. It has two of the Dominion's largest biscuit and candy factories; and is an important brass-working and boot and shoe centre. Other lines represented by numerous firms are: Iron working, carriages, garments, cardboard and wooden boxes, and furniture. London also makes engines, boilers, threshing machines, tractors, cement and concrete products, jewelry, brushes, overalls, cereal products, gas metres, handles, corsets, harness, pork products, show cases, ladders, electric irons, art glass, scales, barrels, hosiery, mattresses, pumps, ale and porter, elevators, soaps, bolts and nuts, bricks, etc.

Manufacturing output, as shown by the last Government census, increased from $8,122,185 to $16,273,999, or over 100 per cent., in 10 years. In relation to population, the price of factory sites in ideal positions is probably lower in London than in any Canadian city. A few hundred dollars will secure a site which would, in all probability, cost as many thousands in the large Eastern centres. Extensive acreage recently added to the city, with every requirement of the manufacturer, has the additional inducement of fixed assessment for fifteen years, with a tax of only fifteen mills on the dollar.

The C.A.S.E. has made no mistake in deciding to go to London for its gathering. The city is noted for its hospitality, for its welcome to delegates. Its transportation facilities are good; its easy distance from Port Stanley, that delightful spot on Lake Erie, is an added attraction. The stage is indeed well and pleasantly set for the 1918 convention.

TRAINING ESSENTIAL TO FUEL CONSERVATION

Intelligent application of the principles of fuel conservation must be practised by every user of fuel throughout the coming twelve months to avoid a repetition of the past winter's plight. Wilful waste under existing conditions must not only be considered as a forerunner of woeful want but at the present time should be recognized almost as a criminal offence. "Keep the home fires burning," must not be taken too literally, but should apply rather to the fires of enthusiasm than to those of the hearth. The growing significance of this continental, if not world-wide, problem was forcibly presented at a recent meeting of the Canadian Railway Club, Montreal, when a paper on the subject of "The Fuel Situation in War Time" was ably presented by Mr. T. Britt, general fuel agent of the Canadian Pacific Railway; the substance of this paper appeared in the April issue of *Power House*. The largest gathering of the season was present, and the subsequent discussion indicated the extreme interest displayed in this momentous question.

Aside from the general adoption of methods and appliances to facilitate the saving of fuel the all-essential factor in the early or ultimate solution of this problem appears to be a better understanding of that ever-changing but equally unknown quantity—the human element. In suggesting that an educational campaign should be conducted among locomotive and stationary firemen, Mr. Britt pointed out the vital importance of personal instruction. He said:

"To my mind this should not be done by printed instructions but by actual illustration by competent firemen. While it is all very well to write a fireman and tell him what he should do, it is far more educational for a competent instructor to show how it should and could be done."

Mechanical devices such as automatic stokers, the superheater, the brick arch, automatic fire door, feed water heater, together with the general design of engine mechanisms have all played an important part in the fuel saving movement, but the highest efficiency of any of these can only be attained when judiciously operated by the engineer or fireman responsible. Commenting on the poor quality of the fuel supplied during the past winter and the difficulties accruing therefrom, W. H. Sample, master mechanic of the G. T. R., said:

"So far as the conservation of fuel with us is concerned, I feel we do not do enough. We have undertaken to do some things but there are a great many more things that we intend to do. We have put on two additional travelling

ON THE SHORES OF LAKE ERIE. PORT STANLEY IS THE FAVORITE SUMMER RESORT IN WESTERN ONTARIO.

firemen with a view of instructing the firemen. That not only helps to save coal but it also assists in getting the trains over the road. We had to hire a great many new men, which is as great as factor in the fuel consumption as anything we have."

In agreeing that the question of fuel conservation was probably the biggest of present day problems, and pointing out the advantages that had resulted from the installation of mechanical devices for this purpose, W. H. Winterwood of the C. P. R. stated:

"A great deal of coal could be saved if measures were taken to prevent it falling from tenders along the right of way. In this connection I wish to say that Sir George Bury, vice-president of the Canadian Pacific Railway, has been vitally interested in the matter of fuel economy for years, and an order issued by him in the past was that locomotive tenders were not to be overloaded, and that the proper amount of fuel to be carried on the tenders be ascertained and that amount not exceeded. This has resulted in a great saving of fuel. He is also responsible for a modification and improvement in the design of our locomotive tenders. This change in design consists of a coal space with a very steep slope at the back which is brought much closer to the shovelling sheet than on any other tenders. The sides of the hopper are somewhat higher, but the coal in the hopper comes down by gravity to the shovelling sheet, eliminating the necessity of a mechanical coal passer and which insures all coal in the hopper being available. This has resulted in a great saving."

It was pointed out that it was not sufficient to equip an engine house or locomotive with fuel-saving devices, but in order to obtain the greatest efficiency from such installations it was imperative that the users should understand them thoroughly. In this connection, E. S. McMillan said:

"The Grand Trunk has spent a large amount of money on mechanical devices to save fuel and also to assist the firemen; as to teaching the firemen, we do this all we can, but it is very difficult on account of the large number of new men employed. I think the men co-operating with the engine crew in train handling should be properly trained in their work, for if not they can waste more fuel by unnecessary work than the engine crew can save. This condition will discourage the firemen very quickly."

In commenting on the vagaries of the human element and the direct bearing this often had on industrial problems, T. C. Hudson, master mechanic of the Canadian Northern, remarked:

"I feel that we should give more attention to young and inexperienced firemen, for that is where we meet most of our trouble to-day. Although we may have ideal conditions—such as locomotives equipped with superheaters, pneumatic firedoors, injectors proper size, tubes cleaned, and front end of locomotives properly adjusted, yet unless you have a fireman who can and will handle the scoop properly, coal will be wasted. It is true that we have a lot to contend with on the railroads in breaking in new men for road work owing to the fact that many skilled engineers have volunteered for overseas service. I am strongly in favor of travelling firemen who can accompany new and inexperienced men and demonstrate to them the proper method of firing a locomotive. You may equip a locomotive with all the fuel-saving devices possible (and the railways of this country have spent considerable on fuel-saving devices) but in the end we must come back to the human element if we are to get the best results. Printed instructions on fuel economy are beneficial from which an energetic fireman may learn much which will help him in his work, but these should be emphasized, and this can only be done thoroughly by demonstrating with the scoop on the footplate of the engine. We must admit that some of the coal supplied this year is of an inferior quality. However it is all we can get to handle the tonnage, therefore the fireman becomes a large single factor in any campaign to secure immediate results. Owing to the shortage of supply it will be found cheaper to educate the fireman than pay for the coal."

The better training of locomotive firemen was dealt with at some length by E. W. Sawyer of the I. C. school, and the thoroughness of this company's methods of education was demonstrated in his statement; he said in part:

"We have had an expert riding engines on one of the larger roads in and out of Montreal for some time in an effort to work out a system which would better results from the coal now being used on the locomotives on the road referred to, and it seems that it is not so much a matter of economy at this time as it is to evolve a system of handling this fuel and to keep the engines hot, especially when the fires get dirty and the grates clog with ash and other debris which so frequently occurs where coal is furnished high in non-combustible material."

Departing from the general groove of the discussion, A. M. Barry, of the St. Lawrence Welding ompany, brought up the subject of the firing and operation of marine boilers and their relation to the general problem of fuel preservation. To quote Mr. Barry in this connection:

"We have heard from the railways on the responsibilities of this fuel question and we have also heard from the power house man. What about the steamboa man? The steamboat man brings us back to the question of the human element. The steamboat man generally is a "wop" and is the cheapest kind of man that can be got. He knows nothing about fuel economy. His type is strong in the arm and thick in the head; his business is to shovel coal. You can see these marine boilers all over the country, in dredges, boats and elsewhere, with leaky and dirty tubes, tubes blocked and boilers dirty—two or three injectors on some to keep the water in them. The railroad man here to-night is being blamed for this fuel shortage but it seems to me that the steamboat man is equally responsible. When the fireman gets to the end of a trip he goes on a drunk, and if he does not turn up again it does not matter as they can get along without him. I do not mean the deep sea men, but the men on the inland waters—lake boats, dredges, and so forth. The railroad companies and those owning power plants may have reason to use greater economy in fuel but it seems to me they are not as great transgressors as the steamboat men. Why not get after them as well with education?"

From the above it would appear that the experience of the past winter will act as a stimulant to the adoption of every mechanical means available for the future saving of coal, especially in those districts where long haulage from the source is necessary. In addition to this increased attention will be given to the education of those men that are directly responsible for the actual burning of the fuel, so that the same may be accomplished in the most efficient and economic manner.

ACCORDING to "The Engineer." an interesting form of spark plug for motor cars is being developed in the United States, utilizing 'catalytic combustion" to keep the carbon burned off the insulators. The method depends on the maintenance of a high temperature by burning part of the gas-air mixture by catalytic flameless combustion throughout the entire period of the compression stroke, when there is plenty of fresh air in the cylinder. The new plug is provided with a catalytic structure, in addition to the electrodes and inculators, which produces heat by oxxidizing the mixture above mentioned. The catalytic flameless combuston produced by this material is distinct from ordinary flame combustion of the kind that inflames and explodes the whole charge of gas and air. The insulator is kept nearly red hot, and therefore does not receive any deposit of soot, but it does not interfere with the electric spark.

IN one of his journals, Camille Flammarion gives the heights at which sounds from the earth are heard from balloons. The shout of a man was heard distinctly at the height of 1,600 ft., the short note of a mole-cricket at 2,500 ft., and the croaking of frogs in a morass at 3,000 ft. At 3,255 ft. a man's voice and the rolling of a cart were distinguished; at 4,550 ft. the roll of a drum and the music of an orchestra; at 5.000 ft. the crowing of a cock, the sound of a church bell, and sometimes the shouting of men and women. Nine hundred feet higher still he heard the report of a musket and the barking of a dog. The noise of a railway train penetrated to a height of 8,200 ft., and the whistle of a locomotive engine to nearly 10,000 ft.

Sixty Ton Electrically Operated Raw Water Ice Plant

Artesian Well, Hydro Power and Well Designed Equipment Characterize Local Plant of London Cold Storage and Warehousing Co.

By W. G. Walters

(Local Secretary, Canadian Association of Stationary Engineers.)

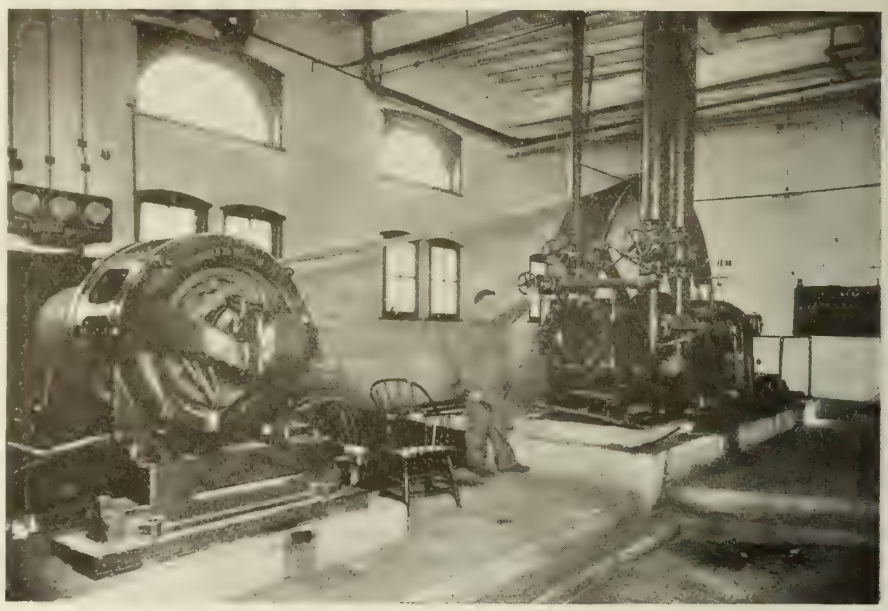
ONE of the important establishments of the prosperous city of London is the artificial ice plant owned and operated by the London Cold Storage & Warehousing Co. Some five years ago this firm, seeing the need for and possibilities of an industry of this kind, asked for tenders on a plant with a capacity of 60 tons of ice per 24 hours. The De La Vergne Machine Co. of New York were successful in securing the contract and designed the plant and furnished the drawings for the buildings in connection therewith.

The low cost of electric power in London was the deciding factor and led to the choice of raw water ice in preference to the more costly process of distilled water.

Water Supply

An artesian well on the premises was sunk to a sufficient depth to secure suitable water and in this respect the plant has a generous supply of beautiful sanitary and palatable water, which makes a very hygienic and pure ice.

The well is pumped by a Luitweiler double acting three stage pump which is driven by a 15 H.P. Crocker-Wheeler induction motor, and it might be as well to state at this time all the power equipment in the cold storage and artificial ice plant is now Hydro operated, at 25 cycle, 3 phase, 550 volts., the change from steam to electric drive being made by the writer in 1912. This Luitweiler pump discharges the water directly over the ammonia condenser, a branch pipe being taken off the discharge line to supply the ice plant for ice making purposes.The water from the condenser is collected and again circulated by a centrifugal pump direct connected to a 7½ H.P. Crocker-Wheeler motor.



60-TON ICE CAPACITY DE LA VERGNE COMPRESSOR DRIVEN BY 150 HORSEPOWER CROCKER-WHEELER THREE PHASE MOTOR.

ELECTRICALLY DRIVEN LUITWEILER PUMP INSTALLED IN ARTESIAN WELL.

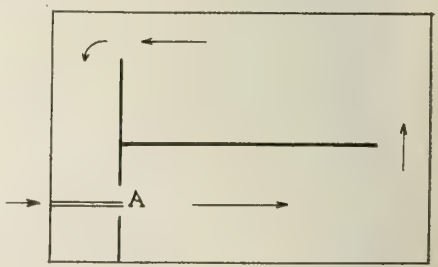
Tank Equipment

The tank room, ice storage, and precooling tank room are all contained in a building 48 ft. x 100 ft. There are 2 ice tanks, each being 41 ft. 6in x 20 ft. 9in. tanks 5 ft. deep. The tanks were constructed by the firm of E. Leonard & Sons, of London. The plates being of steel ⅜ in. thick, tanks were laid out and drilled at the above firm's shops and riveted together on the job. A cement floor was first laid under the tanks and covered with two plies of 2-in. cork board laid in hot asphalt; this with a heavy coat of hot asphalt made a good insulation for the bottom of the tanks.

The first tank was set up on timbers, riveted and caulked, filled and tested, and then lowered into position by the use of chain blocks. Owing to strains in lowering this tank several leaks were discovered. The tank was raised and made tight, and to avid straining again blocks of ice were placed under the tank which melted gradually and allowed it to take its position. This was so satisfactory that this method was adopted for lowering the second tank. The brick walls on the sides were heavily coated with hot asphalt and 10in. of granulated cork used for insulation. Each tank was constructed with a partition as shown, an agitator being placed at (a) which circulated the brine in tank. These agitators were belt driven by a 5 H.P. motor placed on the wall above the tanks.

Coils and Capacity

The ammonia coils for each tank are composed of 18 coils, 10 pipes high, made of 1¼ extra heavy pipe, all pipes being well tinned at the joints and sweated in, and all flanges well soldered. Top of tanks is covered with a wooden frame with doors lifting up to uncover 4 cans of ice. The arrangement of the coils in the tanks allows the placing of 272 cans



CIRCULATION OF BRINE IN TANK

INTERIOR OF STORAGE ROOM. NOTE THICKNESS OF CRYSTALLINE CORE IN SIDE VIEW OF BLOCK

of 4000 lbs. in each tank, size of cans being 57½in. x 22½in. by 11¼in. The capacity of each tank is 30 tons of ice every 24 hours, which means that each can has to be filled and frozen in about 4 ——

The brine for the tanks is made from rock salt, the amount for the first charge being about 60 tons, or a little more than 15 lbs. of salt per cubic ft. of brine.

Insuring Transparency

In the manufacture of raw water ice the hardest proposition that the manufacturers of ice making machinery have encountered is to get their ice transparent—all sorts of devices and equipment have been tried to get this effect. Although the ice is just as efficient and just as sanitary for any purpose even if it does look like snow, yet for commercial purposes it often depends more upon its appearance than it does upon its purity. Snow may be pure but it is white because of the presence of a large number of minute air spaces between the crystals of ice, and it is the same in water, which has not been boiled or distilled. The De La Vergne method of getting rid of the minute particles of air held in suspension in raw water and which was used on these tanks, is as follows:- 2 blowers were installed, one for each tank, and connected so that either blower could be used on either tank, or both used if required. An air line consisting of 2in. pipe was run down on both sides of each tank, and branch lines run over the tops. Each branch line supplies 8 cans. A ¼in. pipe is dropped down into each can.

In course of operation a certain number of cans are filled, air connected and started. The attendant marks on a chart the hour that the cans are filled, and after the freezing has been in progress 12 hours the lids are lifted, the air shut off, and what is known as a core sucker is used. This is an instrument that is dropped down into the can and is connected by hose with a pump, which removes all the water that is not then frozen. The ice in the can is then washed, the wash water removed, and the can refilled, after which the air pipe is placed and left until almost frozen. The air pipe is now removed, the impure water sucked out and again refilled, closed down, and allowed to freeze solid. By referring to view of ice storage this process will be more fully understood.

Capacity and Storage

Above each tank is a travelling crane which serves any part of the tank space. On each of these cranes or travelling cars is a Sprague ½ ton electric hoist, which removes 2 cans from the tank and delivers them to a thawing tank, which thaws the ice enough where it comes in contact with the can to allow it to come out. The hoist then delivers cans to a dump which is operated by the attendant's foot and shoots the ice into the ice storage.

The water for ice making purposes is taken off the discharge from the deep well pump, put through an international filter and then into a pre-cooling tank. This tank has sufficient coils in it to bring the water to a temperature nearly freezing.

The ice storage has a capacity of about 500 tons of ice and is well insulated with cork board. See illustration of ice being piled. An elevator is being installed to hoist the ice up to the ceiling and also to hoist the ice for icing cars. Being right on the main line of the Grand Trunk Railway, considerable trade in icing refrigerator cars is taken care of.

Compressor

The compressor (see view) is one of the largest in Ontario, and is a De La Vergne of 125 tons refrigerating capacity, or 60 tons ice-making capacity. This machine is belt driven, and is operited by a 150 H.P. Crocker-Wheeler slip ring motor with a Cutler-Hammer controller with 12 resistance grids of sufficient capacity to allow of a variation in speed from 8 revs. per min. up to full speed of 65 revs. per min.. A Condit Circuit Breaker with overload relays and no voltage release is provided. Belt is double-ply oak tanned leather 28 in. wide and is driven off motor by a paper pulley 28 in. by 28 in. The condenser used in conjunction with this machine is illustrated herewith, and consists of 8 stands of 2 in. pipe, 12 pipes high.

The piping from machines is so arranged that any one of four machines can be used on ice tanks or on the refrigerating rooms in connection with the cold storage. A section of the old engine room is reproduced showing one of the

VIEW OF SECTION OF OLD STEAM PLANT, SINCE CONVERTED TO ELECTRIC DRIVE BY REMOVING THE STEAM SIDE

35 ton Linde machines. There are two of these machines and also one 60 ton Linde machine, which are all driven by squirrel cage induction motors.

PROGRESS IN POWER PLANT DESIGN

Remarkable improvements have been effected since the older types of water wheels were replaced by turbines. In 1870 the average horse-power of each wheel made by one of the leading turbine makers was only 70; thirty years later it was 700; forty years ago the construction of a wheel giving 500 horse-power was considered something of an achievement; to-day there are at work wheels of 10,000 horse-power and over. It is estimated that in hydro-electric power houses there are now not less than 2,000,000 horse-power of turbines installed.

It was not until the year 1862 that the cylindrical boiler met with any degree of success, and it is a somewhat remarkable fact that this type now remains in almost universal use, and has only been altered in detail since that early period. The water-tube boiler now being manufactured by many firms can be adapted with more ease to the particular requirements it has to meet than any other boiler of the shell type. In marine engines the introduction of the triple-expansion type working at about 150-lb. pressure has enabled great economies in steam consumption to be effected.

Translated into fuel consumption the triple-expansion engine was said to require from 1.46 lb. to 2 lb. of coal per indicated horse-power per hour, while the compound engine requires from 2.32 lb. to 2.39 lb. The steam turbine for any power over 1,200 horse-power shows an even lower steam consumption. Summarizing the results of a large number of tests, it might be said that with 160-lb. pressure, 100 deg. Fah., and 27-in. vacuum, a 3,000-kilowatt turbo-alternator set would take only 16 lb. of steam per kilowatt hour. In the 40,000 horse-power turbine, recently constructed for a Chicago power house, the steam consumption was guaranteed not to exceed 11.25 lb. per kilowatt hour, with steam at 200-lb. pressure and a superheat of 200 deg. Fah. In the case of the geared turbine employed in marine service the London and South-Western Railway steamers Hantonia and Normannia, which are notable examples of this application, were said to show a saving of 40 per cent. over ordinary turbine steamers on the same service.

LARGE GAS ENGINES

The sphere of usefulness of the large-power gas engine is confined mainly to situations where so-called waste gas can be obtained, as at coke ovens and blast furnaces, or where chemical plant is already installed. Iron-masters are unfortunately even now by no means unanimous in their desires for these generators. There can be no doubt, however, that where waste gas is available the large-power gas engine is desirable. The side issues in works power plant also require consideration, as they frequently present the determining factors in the power plant problem. The utilization of exhaust steam in turbines, of blast furnace and coke ovens gas in large-power gas engines, and the development of the storage battery in connection with the fluctuating loads in large works are all problems of remarkable interest.

SMALL GEARED TURBINES

To drive small electric lighting outfits, exciter units for large alternators, or for direct mechanical drive, there has been a demand for a line of steam turbines which would be constructed along the same lines which give durability, ease of adjustment, and high economy to the larger turbine units. To meet this demand, which now comes principally from our new merchant marine for lighting sets, the Westinghouse Electric & Manufacturing Company has developed a line which is being manufactured in sizes from 15 to 50 Kw. for direct-current service; from 30 to 50 Kw. for alternating current service, and from 30 to 100 h.p. for mechanical drive.

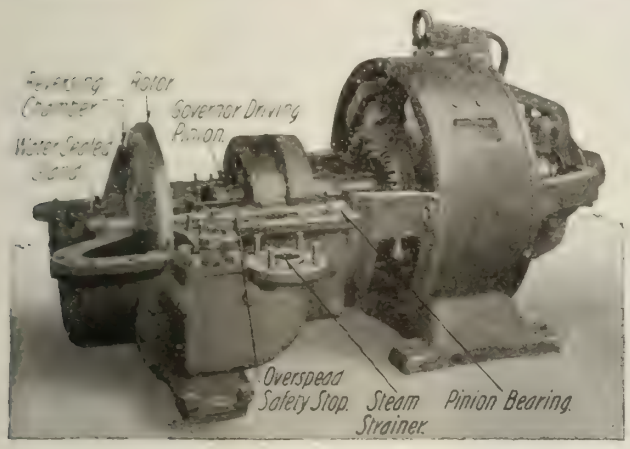
This machine is a geared unit, very compact, and of rugged construction, as shown in the view of the direct-current unit, Fig. 1. The turbine operates at a speed of 7,200 r.p.m. and it is suitable for both condensing and non-condensing operation. It is built for normal operation on any steam pressure from 75 pounds to 250 pounds and for non-condensing operation on any back pressure up to 20 pounds. It embodies the three-point suspension principle, being supported by two lugs on the generator and one under the centre of the turbine, thus maintaining perfect alignment of the turbine, gear and generator.

The generator is of the well-known Westinghouse "SK" type, compound wound, with commutating poles. This design insures sparkless commutation even at heavy overloads, without shifting the brushes—an important advantage since no attention is required to adjust for changing loads. Coils are impregnated by the vacuum process, making them proof against even extreme dampness. The outboard generator bearing is supported by a single-piece bracket bolted to the frame. In this a steel shell lined with babbitt forms the bearing itself; it is pressed and pinned into place and in case of trouble can readily be renewed by driving out with heavy hammer. Oiling is by a ring running over the shaft and dipping into an oil well. The shaft may be pressed out of the armature without disturbing the connection between coils and commutator. Liberal spaces for ventilation are provided.

The internal construction of the turbine is practically identical with that of the larger machines. It consists of a single rotating wheel with blades or buckets around its periphery; the steam from the directing vanes or nozzles impinging against these blades causes the wheel to rotate and the work to be performed. The full energy of the steam is extracted by using only one wheel with the aid of what is commonly known as the re-entry principle; that is, the steam after passing through the blades the first time is changed in direction by means of a reversing chamber and is directed against the blades a second time. The nozzle and reversing chamber are made of phosphor bronze designed specially to resist the erosive action of steam at high velocities. In the 15 and 25 kilowatt units, the nozzle block contains but one nozzle, while in units from twenty-five to fifty kilowatts capacity the block contains two nozzles, one of which is controlled by a hand-operated valve; at partial loads this valve may be closed and thus the water rates are greatly de-

creased, and a much higher efficiency is obtained.

Bearings on the turbine end of this machine are of cast iron, lined with babbitt. Those on the rotor and pinion shaft are of the adjustable type; thus making it possible to keep a perfect alignment between pinion and gear, at all times. The outboard generator bearing is a steel shell, lined with babbitt, pressed into the housing and pinned in place. It is ring-oiled. The pinion is milled out



TOP CASING REMOVED SHOWING GEARS AND TURBINE CONSTRUCTION.

of the solid rotor shaft, thus entirely eliminating the coupling previously used to connect the pinion and rotor shafts.

These machines are fitted with standard water sealed glands of brass, shrunk on the shaft. These glands seal the turbine casing around the shaft, and prevent steam from escaping when operating non-condensing, or they prevent air from entering when operating condensing. By using water glands in place of metallic or other similar glands, the friction loss is greatly reduced, and wear is entirely eliminated, thus doing away with the replacing of parts at regular intervals, as is necessary with metallic glands.

It is a recognized fact that no governor is more reliable than the slow speed governors used on Corliss engines. The governor on this unit is of the low speed vertical fly-ball type, identical in construction with the governors on the larger units. This slow speed is obtained by driving the governor with a pinion on the slow speed gear shaft. The fly-balls are pivoted on knife edges, and they are very sensitive to even slight speed variations in the turbine.

At the base of the governor, and driven by the governor spindle, is a gear oil pump which furnishes the oil for both turbine and gear. The bottom of the gear housing is used as an oil reservoinr, the pump lifting the oil from this reservoir to the top of the gear case from where it flows by gravity through the oil strainer and to the bearings and other parts needing lubrication. The oil is kept cool by a copper cooling coil in the bottom of the oil reservoir through which cold water is kept continuously circulating.

One of the special features on this unit is the automatic throttle valve, operated directly from the governor by means of a connecting rod. This valve is of the balanced type and very sensitive in operation, thus insuring a close speed regulation.

One of the latest refinements provided on very few small turbines is the overspeed governor release. This is a simple device contained in a small hole drilled in the shaft between pinion and rotor, and it consists of a cylindrical weight held in place by a coil spring surrounding it. In case the turbine should speed up to ten per cent. above normal speed, the weight due to centrifugal force overcomes the spring tension and protudes a short distance from its normal position. By so doing, it comes in contact with a lug, which, in turn, is fastened to a lever, the movement of which trips the throttle valve catch and allows the valve to be closed by a heavy coil spring.

This line of turbo-generators conforms to the Navy Department's specifications for ship service, being provided in this case with both steam and water-sealed glands and non-corrosive brass piping.

THE ECONOMICAL RECONSTRUCTION OF BELGIUM

In view of the critical situation which will result for Belgium through the disasters caused by the depredations of the enemy—his removing of tools, raw materials, manufactured products, &c. — there has been created, with the co-operation of, and under the control of the Belgian Government, an organization having for its object the economical reconstruction of the country, and styled "Comptoir National Pour la Reprise de L'Activite Economique en Belgique" (Societe Co-operative). This organization has for its aim, by helping industry and trade, and by enabling the Belgian people to purchase tools and the necessary raw materials, not only to reconstruct the economical fabric of the country, but to put an end to the sufferings of the working classes by making it possible for them to start working in the reconstructed shops. In a letter which the newly formed body has issued it is explained that everything interests it, as everything has to be set up again: metallurgy, materials for construction of buildings, leathers, textiles, farming implements, chemical products, wood machines, electrical material, optical instruments, motor cars, vans, wagons, oils and greases of all kinds, refractory materials, &c. In order to enable it to place orders, manufacturers and merchants are requested to send their catalogues and price lists in triplicate to it at 110, Cannon-street, London, E. C. 4., England.

UNIFORM BOILER LAWS IN U.S.

THE American Uniform Boiler-Law Society, organized for the legal adoption, chiefly by state legislatures, of the A. S. M. E. boiler code, is to make a special effort this year to secure legislation in the States of Georgia, Kentucky, Louisiana, Maryland, Massachusetts, Mississippi, Rhode Island, South Carolina and Virginia, where the legislatures convene this year. Up to date the code has been adopted by most of the important industrial states, including New York, Pennsylvania, New Jersey, Ohio, Indiana, Michigan, Wisconsin, Minnesota and California. It has also been adopted by the cities of Chicago, St. Louis and Kansas City, independently of the State legislation.

Factories' Power Plant

THE McClary Mfg. Co. has two main factories: the foundry, where much of the stove work is done, and the wares factory, where many of their other products are made. Each of these factories has its own power house supplying the power necessary over and above that available from the Hydro-Electric System.

The power house supplying the wares' factory is located in one of the factory buildings near the G.T.R. station and forms a compact and well arranged lay-out as will be seen from the plan.

Boiler Room

This plant is equipped with four boilers of 125 h.p. each, manufactured by E. Leonard and Sons. These boilers are 72 in. by 16 ft., and are enclosed in the usual brick setting with the breeching running directly into a Custodis radial brick chimney 5½ ft. by 125 ft. high.

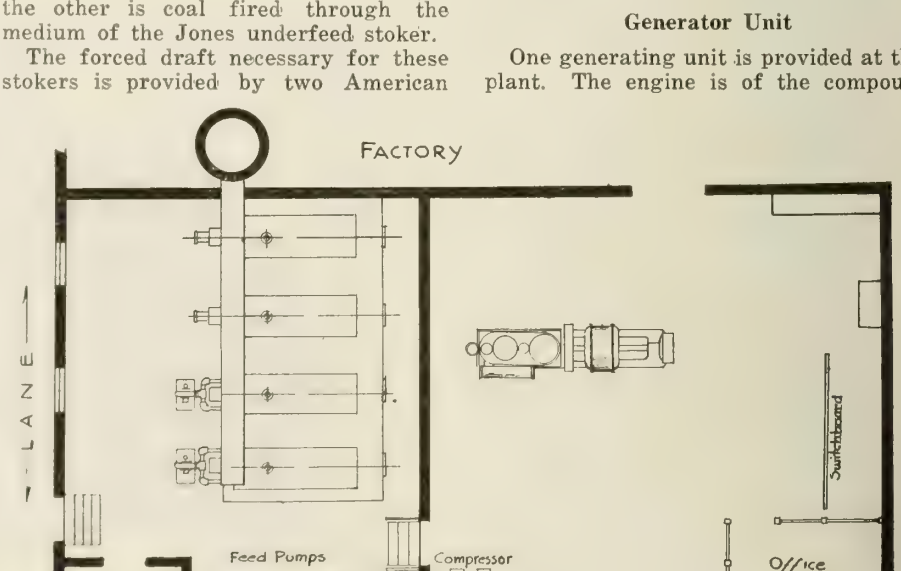
Natural gas is fired under two of the boilers, each boiler being provided with a Premix gas burner which, as will be seen from the accompanying view of the boiler room, consists of a fan driven by a countershaft. The gas is taken in through a 1¼ in. inlet located in the center of the air inlet which is provided with a circular shutter for air regulation. The mixed gases flow through two burners per boiler and impinge on a fire-brick baffle wall placed in front of the bridge wall of the boiler. The Jones underfeed stokers with which all boilers are equipped are left in position and it is a comparatively simple matter to start a coal fire under the two gas-fired boilers whenever desired. Of the other two boilers one is held in reserve while the other is coal fired through the medium of the Jones underfeed stoker.

The forced draft necessary for these stokers is provided by two American blower engines with 5 x 5 cylinders direct connected to fans of the same make.

The feedwater is taken directly from the city mains and is heated in a 500 h.p. Webster feed-water heater by exhaust steam. Two duplex feed pumps are provided, one made by Darling Bros. and the other of Canada Foundry make.

Generator Unit

One generating unit is provided at this plant. The engine is of the compound



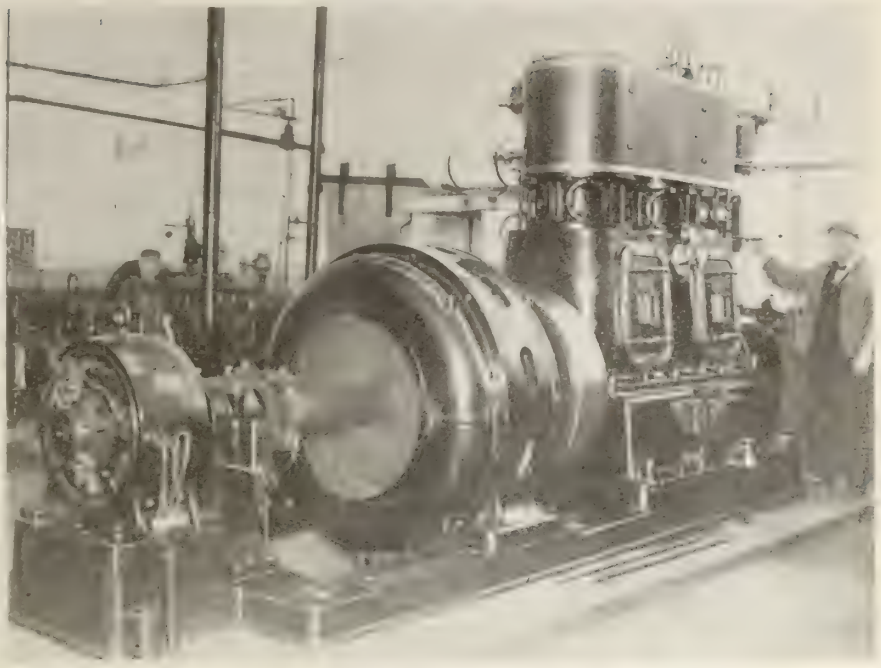
PLAN OF THE WARES FACTORY POWER HOUSE, McCLARY MFG. CO.

vertical quick revolution forced lubrication type made by E. Leonard and Sons. This engine runs non-condensing and has two cylinders 13 and 18 in. diameter by 8 in. stroke. The steam pressure is 115 lbs. and the engine is provided with both throttling and automatic cut-off governing. This combination results in a very economical consumption of steam under all the load factors encountered.

Factory operations requiring the use of exhaust steam and the use of exhaust steam heating in winter render it feasible to run this plant non-condensing.

A 125 kv.-a 550-volt 25 cycle generator of Canadian Westinghouse manufacture is direct connected to this engine. The stator of the generator is not split, and for access to rotor and stator coils an extra length bed-plate is provided, along which the stator is moved when required. A 5 kw. exciter is provided on the end of the shaft.

An additional engine is located in the stamping shop near by and is belted to the line shaft supplying the presses and other tools. This engine is of E. Leonard & Sons manufacture, horizontal, self-lubricating type with a 12 in. diameter by 12 in. stroke cylinder.



LEONARD COMPOUND ENGINE AND WESTINGHOUSE A.C. GENERATOR AT THE WARES FACTORY.

Switchboard

The switchboard controlling all plant requirements is located in the main engine room. All shop lighting circuits are controlled by a condit type D 300 amp. triple pole single-throw switch with an integrating wattmeter for metering the load. This equipment is mounted on the first panel to the left as shown in the accompanying photograph.

The generator control panel is located immediately next to the panel above described and is provided with Canadian Westinghouse ammeters, exciter, rheostat, main and field switch.

The third panel provides a means of feeding all shop circuits from either the Hydro-Electric system mains or from the generator. A rotary double-throw switch is provided for this purpose. A Westinghouse graphic wattmeter registers the power supplied by the Hydro system through a small sub-station located on the company's property, while the total plant load is measured by the integrating wattmeter seen at the top of the panel.

The next three panels are for the various departmental switches and feed the various motors used throughout the plant. In all 35 motors are installed, ranging from 100 h.p. to ⅛ h.p.

Oil Pumps for Enamelling Ovens

An interesting feature in connection with this plant is the pumping equipment installed for the supplying of oil to the enamelling ovens. Oil is received from the tank cars and placed in a receiving tank close to the tracks; from this tank it is pumped to a tank located in the factory yard, and from this it is pumped by the small Hall pump seen in the engraving and shown with the small reservoir underneath, to the oil burners in the enamelling ovens.

Compressed air for these burners is supplied by the air compressor shown, also manufactured by the Hall Pump Works, Pittsburg. This compressor has 12 x 12 steam cylinders and 12 in. air cylinders, and supplies air at 30 lbs. pressure for the atomization of the oil. This equipment is all about 30 years old and is still giving remarkably good service. The compressor takes steam for the full stroke, but as this exhaust is used for heating the feedwater, steam consumption is of secondary importance.

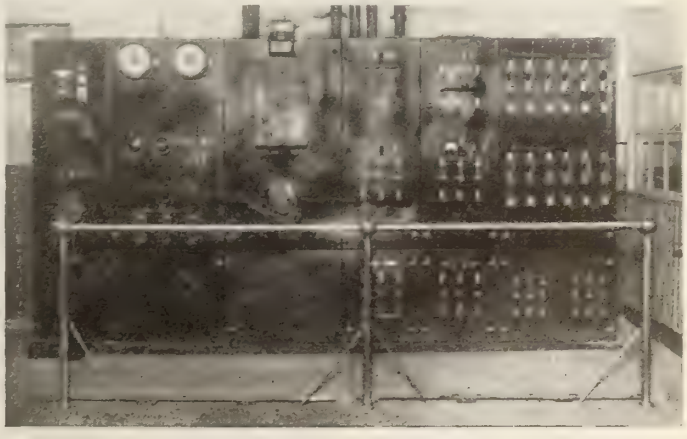
Fire Protection

Fire protection is a very important feature in a plant of this size and a very complete organization has been perfected. An automatic sprinkler system has been installed, and as it is impossible to keep the sprinkler pipes in the colder parts of the plant from freezing in the winter if filled with water, a Grinnel balanced valve system is used. This system is operated by an 8-in. Westinghouse air pump of railroad type, which serves to keep the sprinkler pipes full of compressed air at all times.

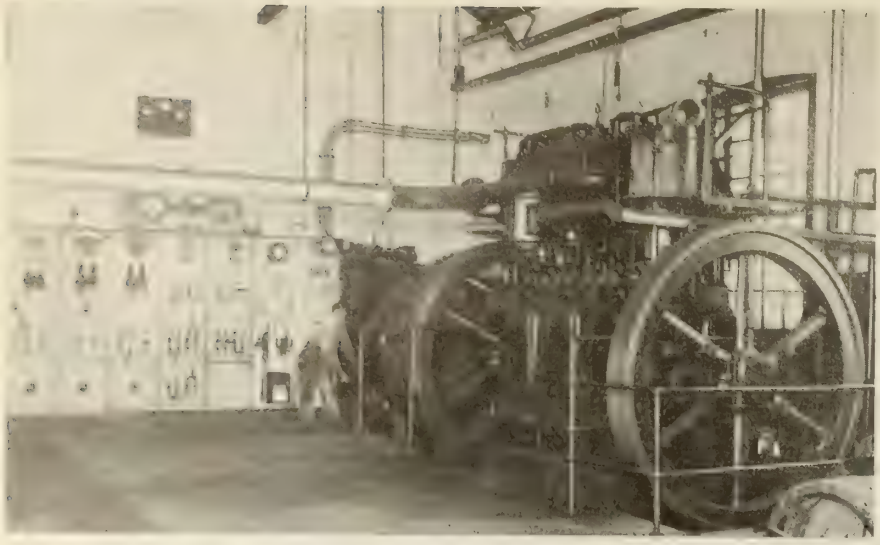
When a sprinkler head gives way the air pressure immediately falls and relieves the pressure on one side of the balanced valves admitting the water under pressure from the other side of the valve and flooding the fire.

In addition to the sprinkler system a Canada Foundry fire pump is installed in a heavy reinforced concrete fireproof

BOILER ROOM AT THE WARES FACTORY POWER HOUSE. NOTE THE GAS-BURNING EQUIPMENT.



SWITCHBOARD FOR CONTROLLING GENERATOR EQUIPMENT AND SHOP CIRCUITS.



WEBER GAS ENGINE UNIT AT THE FOUNDRY POWER HOUSE.

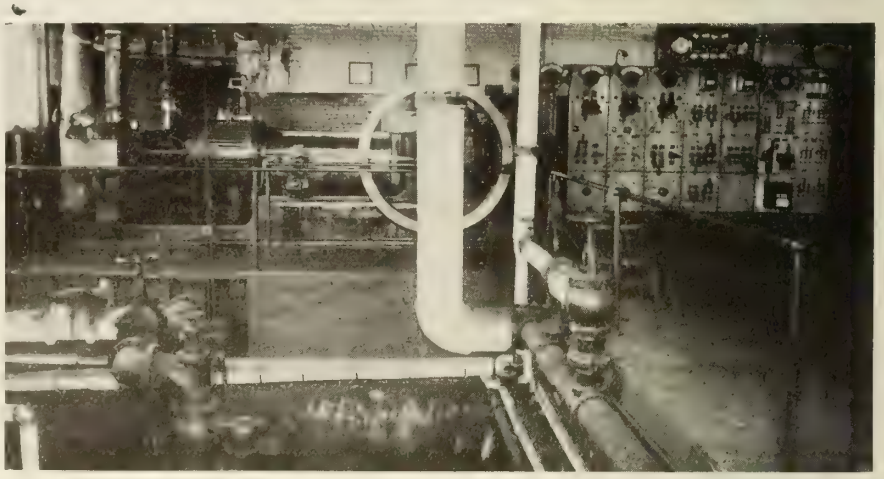
house a short distance from the power house. This pump is fed by an underground steam main and draws water from a 150,000 gallon underground reservoir.

When running at full capacity the pump delivers 1,000 g.p.m. and feeds four 1¼-in. fire streams.

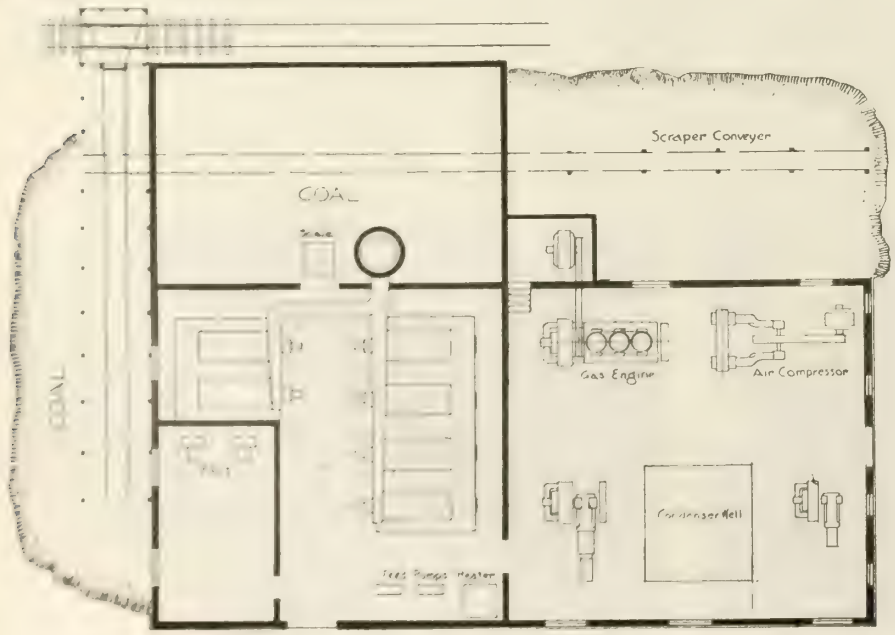
A standing fire brigade of eight men has been organized to fight any fires that may develop, each man having his own particular part of the work to look after. Mr. G. E. Moll, the chief engineer of the factory's power plant, is also chief of the fire brigade, and in addition to the fire brigade has the supervision and training of 150 men distributed throughout the various shops, forming a valuable first-aid to the fire department proper.

Foundry Power Plant

THE foundry power plant is located on the Thames River, closely adjacent to the Adelaide street bridge, and, space being somewhat more plentiful than at the wares factory, is housed in a separate building. This plant supplies what is known as the McClary foundry with 250-volt d.c. power.



LEONARD TANDEM COMPOUND ENGINE AT THE FOUNDRIES PLANT.



PLAN OF THE FOUNDRIES POWER HOUSE, McCLARY MFG. CO.

The London Public Utilities Commission also supplies about 500 h.p. of alternating current power at 550 volts.

Coal Storage

In view of the scarcity of coal during the past winter and the impossibility of securing shipments when needed provision has been made for plentiful storage space and adequate handling equipment. This equipment recently completed elevates the coal from a hopper under the railroad tracks close by and conveys it to either of two outside storage piles shown in the plan or to the main storage space provided behind the boiler room. A scraper conveyer serves to convey the coal from the main conveyer to the storage pile at right angles to its travel.

From the stock piles the coal is wheeled by hand, weighed and fed to the Jones underfeed stokers with which all boilers are equipped. These boilers are six in number, four of them of 125 h.p. and two of 90 h.p., made by E. Leonard & Sons.

It is a well recognized fact that a proper amount of combustion space over the grate bars plays a very important part in the securing of high boiler efficiency and smokeless combustion and a boiler set too low as is the practice in many cases does not allow complete combustion before the relatively cool boiler surface is reached by the hot gases. This trouble has been recogized at this plant and the stoker arrangement has been altered so as to provide a clear space of 5½ feet between the boiler and the stoker hearth, giving excellent results in operation.

Feed Water

Forced draft is supplied for the stokers by Buffalo Forge Co. equipment, consisting of two Spiro gear turbines direct connected to two conoidal fans.

The exhaust from these turbines and from all other station auxiliaries is used for heating the feed water, a Cochrane feed water heater being installed, together with a Lea vee notch recorder. The feed water and coal consumption being known, a close watch is possible on the general plant efficiency.

The feed water supply was formerly drawn from the Thames River near by, but so much trouble was experienced

with mud and sediment that this source was abandoned and the city mains called into service. The feed water is softened in a water treating system recently installed.

The feed water pumps are two in number and are located near the heater. One of them is of Canada Foundry make, 7½ x 5 x 10, and the other is a 7½ x 4½ x 10 pump made by the Smart Turner Company.

Engine Room and Equipment

The engine room is of ample size and houses the generator sets and a Canadian Rand air compressor, used for supplying the foundry pneumatic tools and other equipment. This compressor has a capacity of 465 cub. ft. per min. free air, and is of the two stage type with intercooler. The low-pressure cylinder is 16 in. x 12 in., while the high-pressure is 10 in. x 12 in. A Lancashire a.c. motor of 80 h.p. is belted to the compressor, a weighted idler pulley permitting the short drive installed.

The various requirements of the factories are met by both alternating and direct current motors. The London Public Utilities Commission supplies such 550-volt a.c. service as is required, and also the lighting load at 110 volts, while the 250-volt direct current load is largely carried by the steam plant.

Two direct-connected steam-driven units are provided, both of Westinghouse make. One of these is a 125 kw. 250-volt. d.c. machine direct connected to a Leonard tandem compound Peerless engine with 12 and 20 in. cylinders and 14 in. stroke. The other generator is of similar type and make to the one described above but is only of 50 kw. capacity. It is driven by a 11 in. x 10 in. engine of 75 h.p. and is also of the same make as the one driving the 125 kw. unit.

Both engines are run condensing two Northey jet condensers being provided. These, together with the two outside-packed plunger pumps are located in a condenser well between the two engines forming a compact and easily accessible arrangement. In the winter time the exhaust steam is used for heating the various buildings, a Dunham vacuum system being installed throughout.

A third Westinghouse generator forms part of the equipment and at present is driven by a 200 h.p. Westinghouse motor supplied with 550-volt a.c. power from the Public Utilities Commission. This generator is of the same size and type as the 125 kw. machine above described, and originally formed part of a gas engine-driven unit. This engine, at present disconnected and held in reserve is of the three-cylinder, four-cycle type, and is rated at 200 h.p.

Switchboard

A 7-panel marble switchboard is installed, three panels being taken up with the generator control apparatus. I. T. E. circuit breakers are provided on all three panels. Two panels are provided for d.c. power feeders to the various parts of the foundry and factory. One panel is devoted to the incoming hydro line and its control apparatus. On this panel is mounted a type K General Electric oil switch fitted with a plain overload release, a Westinghouse graphic wattmeter and voltage tap switches for controlling the voltage on the lighting transformers located in the boiler room behind the boilers. The last panel is devoted to the lighting switches for the various shops.

We are indebted to Mr. J. M. Gunn, foundry manager, and to Mr. J. H. Smith, chief engineer and vice-president of London No. 30 C.A.S.E., for the above information concerning the efficiently operated isolated plant.

BOILER ROOM AT THE FOUNDRIES POWER HOUSE. JONES' UNDERFEED STOKERS IN THE FOREGROUND.

Welfare Work

INDUSTRIAL relations between employer and employee are ceasing to be a mere question of dollars and cents. The present time of questioning and search into things long taken for granted will probably bring about vast changes in the attitude at present existing, though with many exceptions, between capital and labor. Human labor is ceasing to be a mere commodity and a growing sense of the employers' responsibility in the welfare of the worker is apparent.

The question of the employee's welfare and comfort is being recognized as one in which the employer has a large

COAL UNLOADING EQUIPMENT.

interest and duty to perform, and it is not alone necessary that each should have a certain interest in the work; the hearty co-operation of employer and employee is essential in any undertaking promoting the welfare of the employee and establishing amicable relations between them.

The McClary Manufacturing Co., of London, have had for some time past a welfare organization well worthy of attention and careful scrutiny. The welfare work is divided into two distinct and separate bodies, known as the Benefit Society and the Welfare Department. The Benefit Society is operated exclusively by the employees, while the Welfare Department is the company's connecting link between itself and its employees, and exists for the purpose of facilitating a better mutual understanding, and serves, as its name signifies, to promote the employees' welfare.

Welfare Department

While the McClary factory is divided into two separate and distinct units, the foundry and the wares factories, the welfare organization embraces both in its efforts to maintain and add to the sincere spirit of friendliness that is characteristic of the company's management.

Lt.-Col. Gartshore, the company's vice-president, has for many years been keenly interested in welfare work, and the success of the welfare organization is in a large measure due to his interest and guidance. The members of the general committee are appointed by Lt.-Col. Gartshore, and from them are chosen the various branches of the department's work. As working head of the department and in touch with the activities of all committees is the welfare supervisor, Miss Frances Rankin.

The department has its foundation in the firm's welfare investment, that is the original investment of space, equipment and time put into the work by the company. This covers the three dining rooms and their furniture, the cafes and their equipment, the two emergency hospitals and their supplies, the professional services of a trained nurse as supervisor, and all clerical work necessitated by the various activities. An annual deficit on account of wages in the cafes is also absorbed by the company.

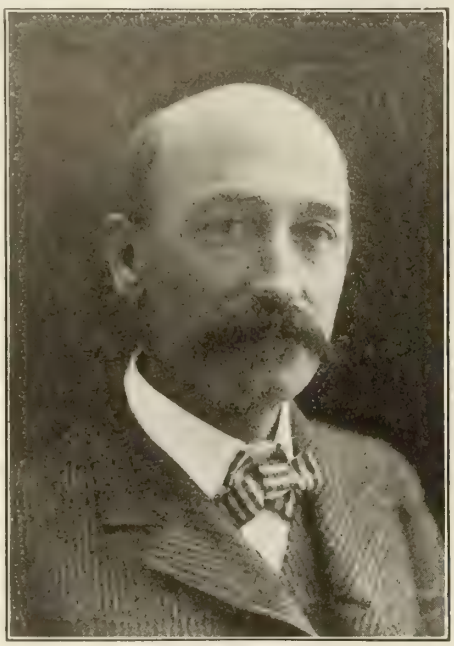
Departments and Organization

The Welfare Association is a body composed of individuals appointed to it by the president, whose duty it is to make suggestions and further by every other means they find possible the spirit and deed of welfare throughout the institution.

From among the members of this association are chosen the committees—the dining room committee and its subcommittees on amusements; purchasing committee, advertising committee, and the garden committee.

The scope of the dining room committees, convened by Mr. John Walton, at the foundry, and Mr. F. Westbury, at the factories, is well outlined by their names, suggestions and improvements relative to the noon-hour service and recreations. A piano and games are provided in each dining room, and effect a very beneficial relaxation between the strain of morning and afternoon work hours. Allied to these are the amusement committees, through whose endeavors are provided talent for a first-class concert once a week. The chairman of these two latter committees are Mr. Tapp, foundry, and Mr. G. E. Moll, factories.

The weekly concerts are a means of developing the musical talent of the employees, and also serve to bring before them the best musical talent of the community and of outside points. In addition to the weekly concert a very enjoyable noon hour is provided one day a week at each plant, at which an address and music are given. Social events and entertainments other than the noon-hour



COL. W. M. GARTSHORE,
Vice-President of the McClary Mfg. Co.

meetings have been greatly curtailed for the duration of the war.

Dining Rooms

Perhaps the most tangible benefit to the employees results from the dining room service. The three dining rooms are of ample dimensions, the largest seating 400 people, and food is is sold at prices very much lower than is possible elsewhere. For those who wish it, a hot meal is served for 25 cents. Tea and coffee are served for 1 cent a cup, bread and butter the same, sandwiches 3 cents, pie 4 cents, and soup for 3 cents, prices which, needless to say, are very reasonable.

The purchasing committee is part of the welfare organization, and buys large quantities of certain provisions, mainly market stuffs, and re-sells to employees only at a slight advantage to the latter. This is, of course, done under arrangement with the city and mainly as a convenience to the employees.

A very welcome source of revenue has been found in the sale of advertising space on the lunch room walls and on menu programmes, etc. Neat frames are attached to the blank spaces of the walls where convenient, in which the advertising matter is placed, and this arrangement proves a good investment to the users of such space.

Gardening

With the call for increased production of foodstuffs last year a gardening committee was formed and proved itself a splendid success. Under its management a considerable tract of otherwise idle land was secured, plowed up by the company's teams, and given out by lot to the applicants for garden plots. Seeds, implements and insectides were bought in bulk and sold to the gardeners at cost. Speakers were secured, who gave lectures on various phases of gardening, which would prove most helpful to those who were amateurs at the work. A competition was also held, several inspections of the gardens entered being made during the season, and prizes and credits awarded at the close.

This committee, in view of the present shortage in foodstuffs, is particularly commendable, and the work planned for the coming season is expected to be of still greater benefit to the employees participating.

Another very much appreciated feature is the savings department operated through the timekeeper's, the paymaster's and the cashier's departments. It constitutes what is perhaps the most painless method of saving known. The employee merely expresses to the timekeeper the weekly amount he wishes to deposit out of his wages, and this sum is deducted from his pay, placed to his credit on the company's books at 5 per cent. interest, and repaid to him, unless he chooses, as many do, to leave it on deposit, early in the last month in the year. Sums as small as 25 cents weekly are accepted. Last year the employees saved over forty thousand dollars.

This year, in addition to the above arrangement, the employee may, if he so wishes, place the amount saved toward the purchase of Victory bonds and war saving certificates.

Each plant has quite a comprehensive lending library run in connection with and forming a part of the dining rooms.

Hospital and Health Conservation

Each has an emergency hospital, the complete appointments and stock of remedies of which make it possible to treat accident patients and those suffering from illness during working hours to the best advantage. The scope of this work may be realized when it is known that Miss Rankin gave 1,322 consultations and made 713 dressings, besides making 1,206 outside visits during the last year. In addition to this hospital service, the welfare department always has on hand such supplies as extra linen, hot water bottles, crutches, invalid chairs, etc., which are loaned to those in need of them.

The Benefit Society

The McClary Mfg. Co.'s Employees Benefit Society was founded in 1882, and is a distinct organization from the wel-

fare department described above. This society is composed entirely of employees, and its affairs of government and administration are directed entirely by officers and committees elected annually by the vote of the members. Its purpose is that of aiding members in distress, especially that occasioned by illness. Two physicians are employed, who give medical attendance and advice free of any individual charge to any member of the organization. In addition to the medical attention, the patient receives a weekly sick benefit.

In cases of death, if it be that of a member, the family receives a claim of $50, and if it be that of a member's wife, the husband receives a claim of $25. Last year there were paid out in sick benefits $3,189.50; in death claims, $375, and in physicians' fees, $1,291.86.

No better evidence of this society's usefulness and popularity can be given than that 95 per cent. of the employees, including the office staffs, are members of the organization.

The society also spends a considerable amount each year in such directions as the annual picnic, Christmas trees, Christmas hampers, and will, on resolution of its committee, make loans, or, where necessary, grant outright funds to members in temporary need of financial assistance.

THE STANDING SHOP FIRE BRIGADE OF THE McCLARY MFG. CO. MR. GEORGE MOLL, CAPTAIN AT THE RIGHT.

We are indebted to Miss Margaret Wade, editor of McClary's Wireless, and to Mr. G. E. Moll, chief engineer of the factories' power plant, for much of the information contained in the foregoing articles.

MECHANICAL ECONOMIZERS

By K. M. E.

THE greatest advances of the past decades have been made in the basic field of the raw materials of mechanism. Modern metallurgy, for example, has made enormous strides, and grows less and less dependent upon initial material of high relative purity. This has set free large quantities of low grade material hitherto not utilizable for highest quality of products, and recently it has been found expedient to allow higher percentage of deterious ingredients to increase production. The increase in permissible contents of phosphorous and sulphur in steel has not been attended with any visible ill-effects, provided always that circumstances condition use. Thus the field of supply has been extended in a double sense with benefit all round.

Hand-in-hand more modern organization serves to give increased individual production, while productive means themselves have been also improved. The economies of waste by its limitation have also been duly studied, and especially process economy in material has been duly enhanced in importance. Practically at every point of the compass the saving virtue of thrift imposed by real necessity has served to give benefits, whose ultimate outcome is difficult to foresee. Elimination of waste, the utilization of inferior raw material without detriment to the finished product, greater ingenuity in mechanism itself, better organization, increased specialization, economy of material itself, substitution of one material for another, all these make productive engineering a field of surpassing interest which will increase rather than diminish in the future.

Problem after problem has been attacked and made to yield some economic result. The entire art of metal working from first to last is altering visibly year by year; at no point is it stable or lacks definite improvement, and no detail is so small as to escape analysis in competent hands. It is quite possible that in the near future iron castings will give way to steel in a universal sense, while the electrical furnace will shift the centre of gravity of the steel trade to new quarters.

To attempt the enunciation of the economic value of all the advances made would be extremely difficult, but as a total they must be immense. Their full exploitation may indeed so enable productive costs to be cut that increased average wages will not hamper the profits of industry and solve the most difficult of all the outstanding problems—that of labor.

THE VEGETABLE SHOW HELD IN ONE OF THE EMPLOYEES DINING ROOMS.

IN the course of an address to the American Institute of Electrical Engineers recently, the president, Mr. E. W. Rice, jun., said that something like 150,000,000 tons of coal were consumed by the American railroads in the year 1917. From the results obtained from electrical operation of railroads it would be possible to save at least two-thirds of this coal if electric locomotives were substituted for the present steam locomotives.

ANNUAL EMPLOYEES FLOWER SHOW.

The Cultivation of Efficiency

Manufacturers of Power Plant Supplies Co-operate With Employees — Work is Made a Pleasure and Pleasure is Made Profitable—Factory Construction and Individual Comfort Are Features of Conditions

By J. H. MacMillan

LOOK backwards a matter of a very few years and consider the working environment of the factory employee. In ninety-nine cases out of a hundred the employer had no interest in "Jim Smith" or "Mary Jones" other than procuring from them a day's work for a day's wages paid. Sanitation was practically confined to hospitals, and the very word was suggestive of the doctor.

Slowly, but just as surely, the manufacturers have been brought to the realization that, in order to obtain one hundred cents on the dollar paid to the employee that consideration had to be given to the mental and physical condition of the human unit of their organization.

Factory construction was the first item that showed the trend of affairs. Daylight buildings of concrete and steel and a maximum of window space appeared. "Texas" and "Saw-Tooth" roofs put in an appearance. Where a board-walk alley had previously been considered sufficient for a passageway between buildings, roadways of full width, cement paved, sprung into view. Hot and cold air systems for mechanically and automatically washing and freshening the atmosphere were added. Sanitary drinking fountains displaced the old germ-laden community drinking cup and dust-laden water barrels. Individual towels, laundered by the company relegated the "wipe" or roller towel to the background, and light, airy toilet rooms took the place of the disreputable foul-odored corners that housed the sanitation facilities (?) of the manufactory of not so long ago. Doctors are employed and paid for by the company to regularly examine those whose duties entail the slightest opportunity for contracting a disorder.

All this, and much more, has taken place to guard the physical welfare of our muscle power.

Then the factory owner even went a step further. Based on the fact that a sick brain is only a small percentage efficient, means of recreation came into being; means to lift the mental power of the human unit away from the daily task in order that the operating functions of that power should be become stagnant by being overfed with the monotony of the day's labor. Club rooms were furnished for the men and women, and from them have grown the spacious rest and recreation buildings that to-day provide the human element of an organization with mental stimulus to render 100 per cent. efficiency at the daily task. All of this is based on the old proverb of "all work and no play," etc.

When you stop to consider that the average employee spends a good deal more time at work than he does at play and at home combined—if you deduct the sleeping hours—it is not any more than fair that his place of employment should be as pleasant as possible.

For many years the various factories and branches of the H. Mueller Mfg. Co., Ltd., manufacturers of water plumbing and gas brass goods, etc., have been carrying out these ideas. To say they are costly is incorrect. The results that accrue more than equalize and justify the cost and upkeep of the institution.

The illustrations presented herewith show, conclusively, the lengths to which the Mueller Company has gone in their Sarnia plant. The plants at Port Huron, Michigan and Decatur, Illinois are equipped likewise. The consensus of the Mueller employees' opinions is the proof conclusive as to the success of welfare work. This work has a moral effect that is alone worth the value of the investment.

The Mueller Company employees have several internal associations, officered and operated by the employees themselves. Foremens' clubs, departmental clubs, etc., an employees' aid society, supported by nominal fees, disburses sick, accident and death benefits. The company itself is back of and supports both morally and monetarily any meritorious, welfare movement that is advanced. Hot tea and coffee is served gratis to each employee at meal times in the recreation building and music is provided and dancing permitted following the meal. Prizes are continually offered for effort along various lines, and co-operation rules in every angle of the big organization.

The writer of this article remembers, some twenty-five years ago, working in a broom factory for one dollar per week. That factory was one of the largest in the business at the time. Every available foot of space was crammed with material and stock at all times. Daylight was at a premium, and fresh air almost unknown. We had a clean-up day every second week for which we didn't get paid—Sunday morning. Anybody caught sweeping the floor around his bench at any other time was fired—with a capital "F." Sometimes the refuse from the broom corn (partially decayed field mice, too, included) was knee high at my bench—I was a "hurl cutter." More than once my stomach revolted and that too, would have to lay. We were positively not allowed to leave our benches except when the whistle blew. Slave-driving methods constituted efficiency of those days. When we contrast conditions such as they were with the modern factory of to-day, we can be excused from wondering how the worker stood his job under the conditions of not so long ago.

There are numerous industries of to-day that have not as yet "seen the light," but they are few and far between. The average factory employee of to-day is the best-cared-for individual in the commercial world—and why not? The human unit is fundamentally necessary to the operation of any industry. We must oil and repair our steeds of steel and fabric; why should be neglect to apply the mental and moral lubricant to our muscle power?

OFF PEAK USE OF ELECTRIC ENERGY FOR HEATING

The use of electricity for heating our homes has been the subject of much controversy during the past few years. The difference of opinion was principally due to the general way in which the subject was treated and the lack of definite detail in the various over-optimistic arguments advanced. The recent coal situation has brought about a more serious study of facts, and the figures now available show that, even if all of our numerous water-powers of Canada were converted into hydro-electric energy, the quantity would still fall short of that required to heat our homes during the winter.

To say that hydro-electric energy cannot replace coal entirely for heating purposes does not mean that it cannot be utilized or that it must be confined to raising the temperature of a cold room a few degrees in the late spring and early autumn. It may, indeed, stimulate the use of more easily available fuels, such as wood and peat. The principal objection to the use of many fuels for domestic heating is that a fire cannot be banked up to last over night, say from 11 p.m. to 7 a.m. Now, this is just the period when a large portion of the hydro-electric equipment installed in the country is lying idle, and the surplus energy then available might well be used to supply heat in at least a few of our homes. This would not only mean a direct conservation of coal, but would render feasible the use of other fuels not requiring to be transported such long distances.

As an example, the hydro-electric energy used in the Montreal district is some 150,000 h.p. with a load factor of about 75 per cent. This "load factor" means that 25 per cent. of the total possible output during the 24 hours is unused, though it could be utilized at certain hours. In other words, during the six colder months, approximately 121,000,000 k. w. h. could be used for heating purposes, without the addition of a single horse-power in the present installations. This is equivalent to some 20,000 tons of coal.

One of the difficulties would be to prevent the energy being used for heating purposes except during the hours when very little energy is required for power and light. This could probably be accomplished by installing at the various heating services a disconnecting relay operated from the central station.

DEVELOPMENT OF AIRPLANE GUN AMMUNITION

CONDITIONS under which airplane fighting has been developed show that a continuous process of evolution has taken place conjointly between protective and destructive equipment. As the war progressed, the more vital parts of the airplane were protected with light armour, so that it became necessary to introduce armour-piercing bullets similarly.

As the gasoline tanks were particularly susceptible to incendiary explosion, it was necessary to procure a bullet containing an inflammable substance, ignited upon discharge, which would carry the spark or flame into the tank upon piercing it.

Tracer Bullet Introduced

As the target, the enemy airplane, was within fighting range for only brief moments at a time, and as there were no means of determining the fire effect as on land, a tracer bullet containing a bright-burning composition, which would indicate the path of the bullet in daylight as well as in darkness, and thereby allow the aim of the machine gun to be corrected, was introduced. The composition is set on fire upon discharge and the bullet flies through the air as a bright spark plainly visible to the machine-gun operator.

All of these cartridges are of the small rifle calibers—caliber .30 or thereabout. The 3/10 of an inch diameter and short length of this bullet left little space therein for the armor-piercing element or for the tracer or incendiary composition. Nevertheless, combinations of armor piercing and tracer and armor piercing and incendiary bullets have been made.

Meet Tests Fully

At the outbreak of the war, further information was promptly gathered from the allies and this subject was studied by those responsible for this work in the United States. Of course, on account of the difficulties of the problem, none of the special bullets possessed by any country is entirely satisfactory or what might be termed "perfect" in operation.

The bullets developed by the United States Ordnance Department have been tested on land and from airplanes to see if there is any difference in their performance when fired from a quickly moving airplane in the upper atmosphere and when fired on land.

These tests indicate that the United States has developed a class of special cartridges with a performance fully equal to that attained abroad.

The Ridout St. Station of the London Public Utilities Commission

By W. F. Sutherland†

HORTON ST. ELEVATION OF THE RIDOUT ST. PUMPING STATION.

URBAN life is increasingly dependent upon adequate provision for sanitation, water supply and light and power. To such an extent is this true that it may be truthfully said a city's possibilities and prosperity depend upon the extent to which provision has been made for the health and comfort of its citizens in these respects.

The city of London is fortunate in the advantages derived from its plentiful supply of pure water and cheap light and power. These, together with its central location and excellent railroad facilities have made it an admirable location for the many manufacturing interests there established.

†Associate Editor Power House.

Public Utilities Commission

On the advent of hydro power in 1914 London availed itself of the advantages offered by centralized control of the public utilities and vested in the Public Utilities Commission, then formed, the supervision of the waterworks, the hydro system then being installed and the parks of the city. That this policy has been advantageous is evident from the progress and development of these municipal enterprises under Mr. E. V. Buchanan, the general manager.

Waterworks, Historical

The waterworks system dates back to 1879 when the first pumphouse, reservoir and mains were built. The present Springbank plant has been formed of the original plant since supplemented and increased by additional steam and electrical equipment.

The buildings have been remodelled and in one instance rebuilt after a dam-

THE WATERWORKS PUMPING STATION AT SPRINGBANK PARK. THIS STATION IS A COMBINATION OF WATER, STEAM AND ELECTRIC DRIVE.

RIDOUT STREET ELEVATION.

aging flood on the Thames River and the mains have from time to time been enlarged and extended, keeping pace with the growth of the city until in all there have been laid 132 miles of watermains varying from 20 inches down to 1½ inches diameter.

In 1917, a volume of 1,650,000 gallons of water was pumped, a per capita consumption of 78 gallons per day.

Water Supply

The supply of water is obtained from three sources; the main pumping station at Springbank, the motor operated wells at Foster's Flats and the air lift wells at the pumping station on Ridout Street.

The Springbank plant is located on the Thames River about three miles from the city. The station and the springs from which the water is pumped form the centre around which an exceedingly attractive park has been formed comprising in all about 400 acres of park land with the usual amusement devices, two band stands, pavilion, bath house and baseball diamonds.

The water collected in the springs and wells at Springbank is pumped to the reservoir of 5,000,000 gallons capacity, 230 feet above Dundas Street, and from there flows by gravity into the distributing mains.

The question of an additional water supply for future requirements has been gone into very carefully, and as a result five wells at Foster's Flats were driven. These wells, which are of 12-inch bore, gave large quantities of water on test and the two which have been fitted with deep well turbine pumps remote controlled from Ridout St. station show no appreciable diminution in capacity although producing 500,000 gallons of water per day each.

Ridout Street Station

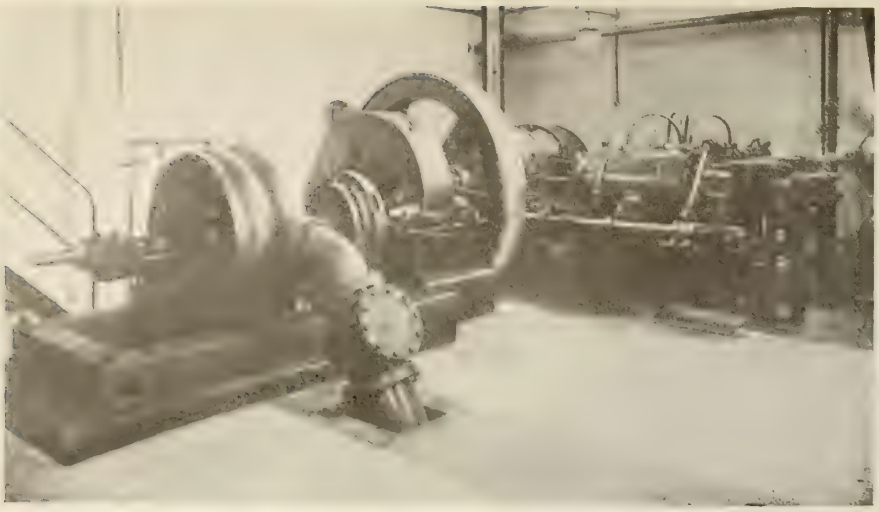
The combined pumping and electrical distribution station located on Ridout and Horton Streets forms an additional source of water supply, supplementing the supply derived from Springbank and Foster's Farm.

As will be seen from the accompanying illustrations the station is L-shaped in plan, the reservoir from which the station pumps derive their supply being located in the centre.

At the rear of the station and at one end of the reservoir a stores building and garage are located. The buildings throughout are of fire-proof construction; brick walls, reinforced concrete and steel combining to make an admirably arranged station of good appearance. The symmetrical and careful arrangement of the architectural features shows little trace of the extensions carried out from time to time consequent upon increased demands for power.

The air lift wells at the Ridout Street station are located on both banks of the Thames River and are eighteen in number. These wells are of 10 in. and 8 in. bore and are all fitted with air lift pumps of the shallow submergence intermittent type. The wells are only 80 feet deep on account of the sulphur-

INTERIOR VIEW OF RIDOUT ST. STATION SHOWING PUMPING EQUIPMENT, EXCITERS AND AIR COMPRESSORS. THE SUBSTATION EQUIPMENT IS SHOWN IN THE BACKGROUND.



GAS ENGINE DRIVEN PUMPING UNIT. THE SYNCHRONOUS CONDENSER UNIT HAS SINCE BEEN ADDED AT THE LEFT OF THIS ILLUSTRATION.

laden water found if any greater depth is reached. The air lift pumps serve to raise the water to a sufficient height in the individual discharge tanks at the top to cause it to flow by gravity into the reservoir of 1,000,000 gallon capacity. This reservoir is of reinforced concrete, and being roofed over keeps the water at all times pure and wholesome.

From this reservoir water flows into a semi-circular pumping reservoir formed at one side and from which the turbine pumps in the Ridout St. station derive their supply.

The station may properly be divided into three parts; that housing the pumping equipment, that supplying the lighting and power load of the city, and that supplying the energy for the street railway and the London and Port Stanley electric road.

Pumping Equipment

From the accompanying photographs and line drawings a good idea of the arrangement of the pumping equipment may be gained. Three turbine pumps serve to pump the water from the station reservoir to the city mains, while the air supply for the air lift pumps is provided by several air compressors.

The main floor has been omitted in that part of the station in which the pumps are situated leaving ample head room from the basement floor to the second floor for the installation of a hand-operated crane.

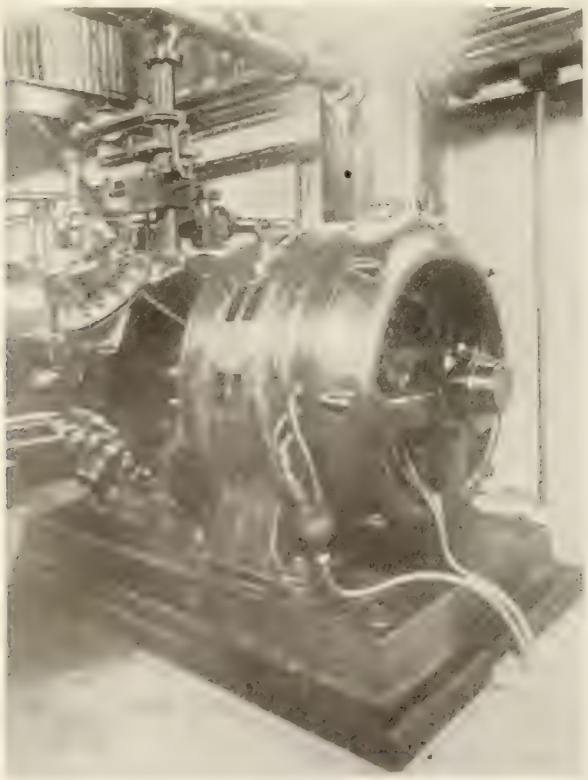
A unique feature in connection with this crane is the method of supporting the crane runways. These are bolted to substantial castings embedded in the walls and also hung from the floor beams above. The weight is taken by the walls and the turning movement of the crane runways is taken care of by the bolted connection to the beams above.

The portion of the electrical substation contained in the same wing of the station as the pumping equipment forms the No. 1 substation, this part having formed the original installation.

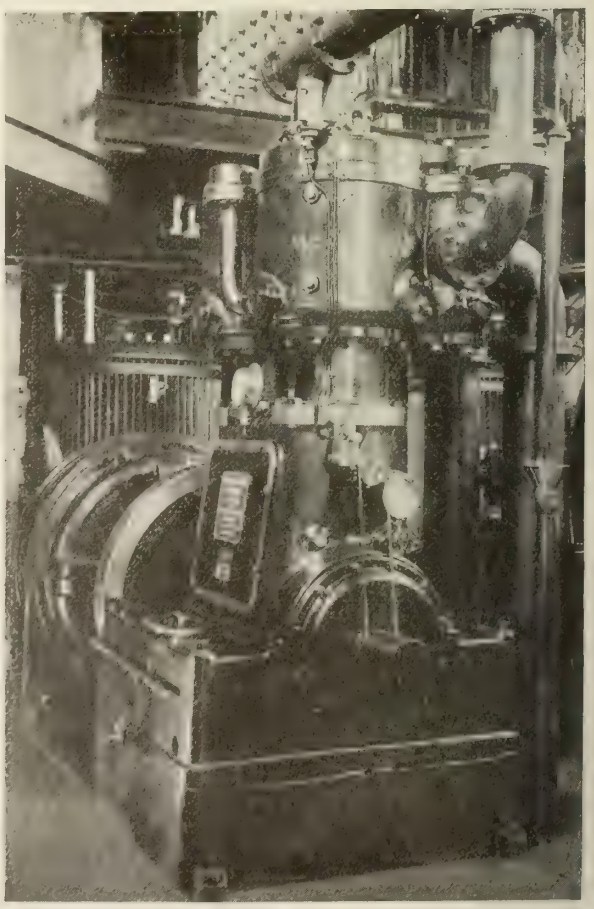
Turbine Pumps

The three turbine pumps are all of the same capacity, 1,500,000 gallons per 24 hours, and are of the Worthington type, manufactured by the Caledonia Iron Works, Montreal. These are two stage pumps with 28 in. impellers, and when running at their rated speed of 750 revs. per min. operate against a static head of 100 lbs. per sq. in. The diameter of the discharge from each is 8 in.

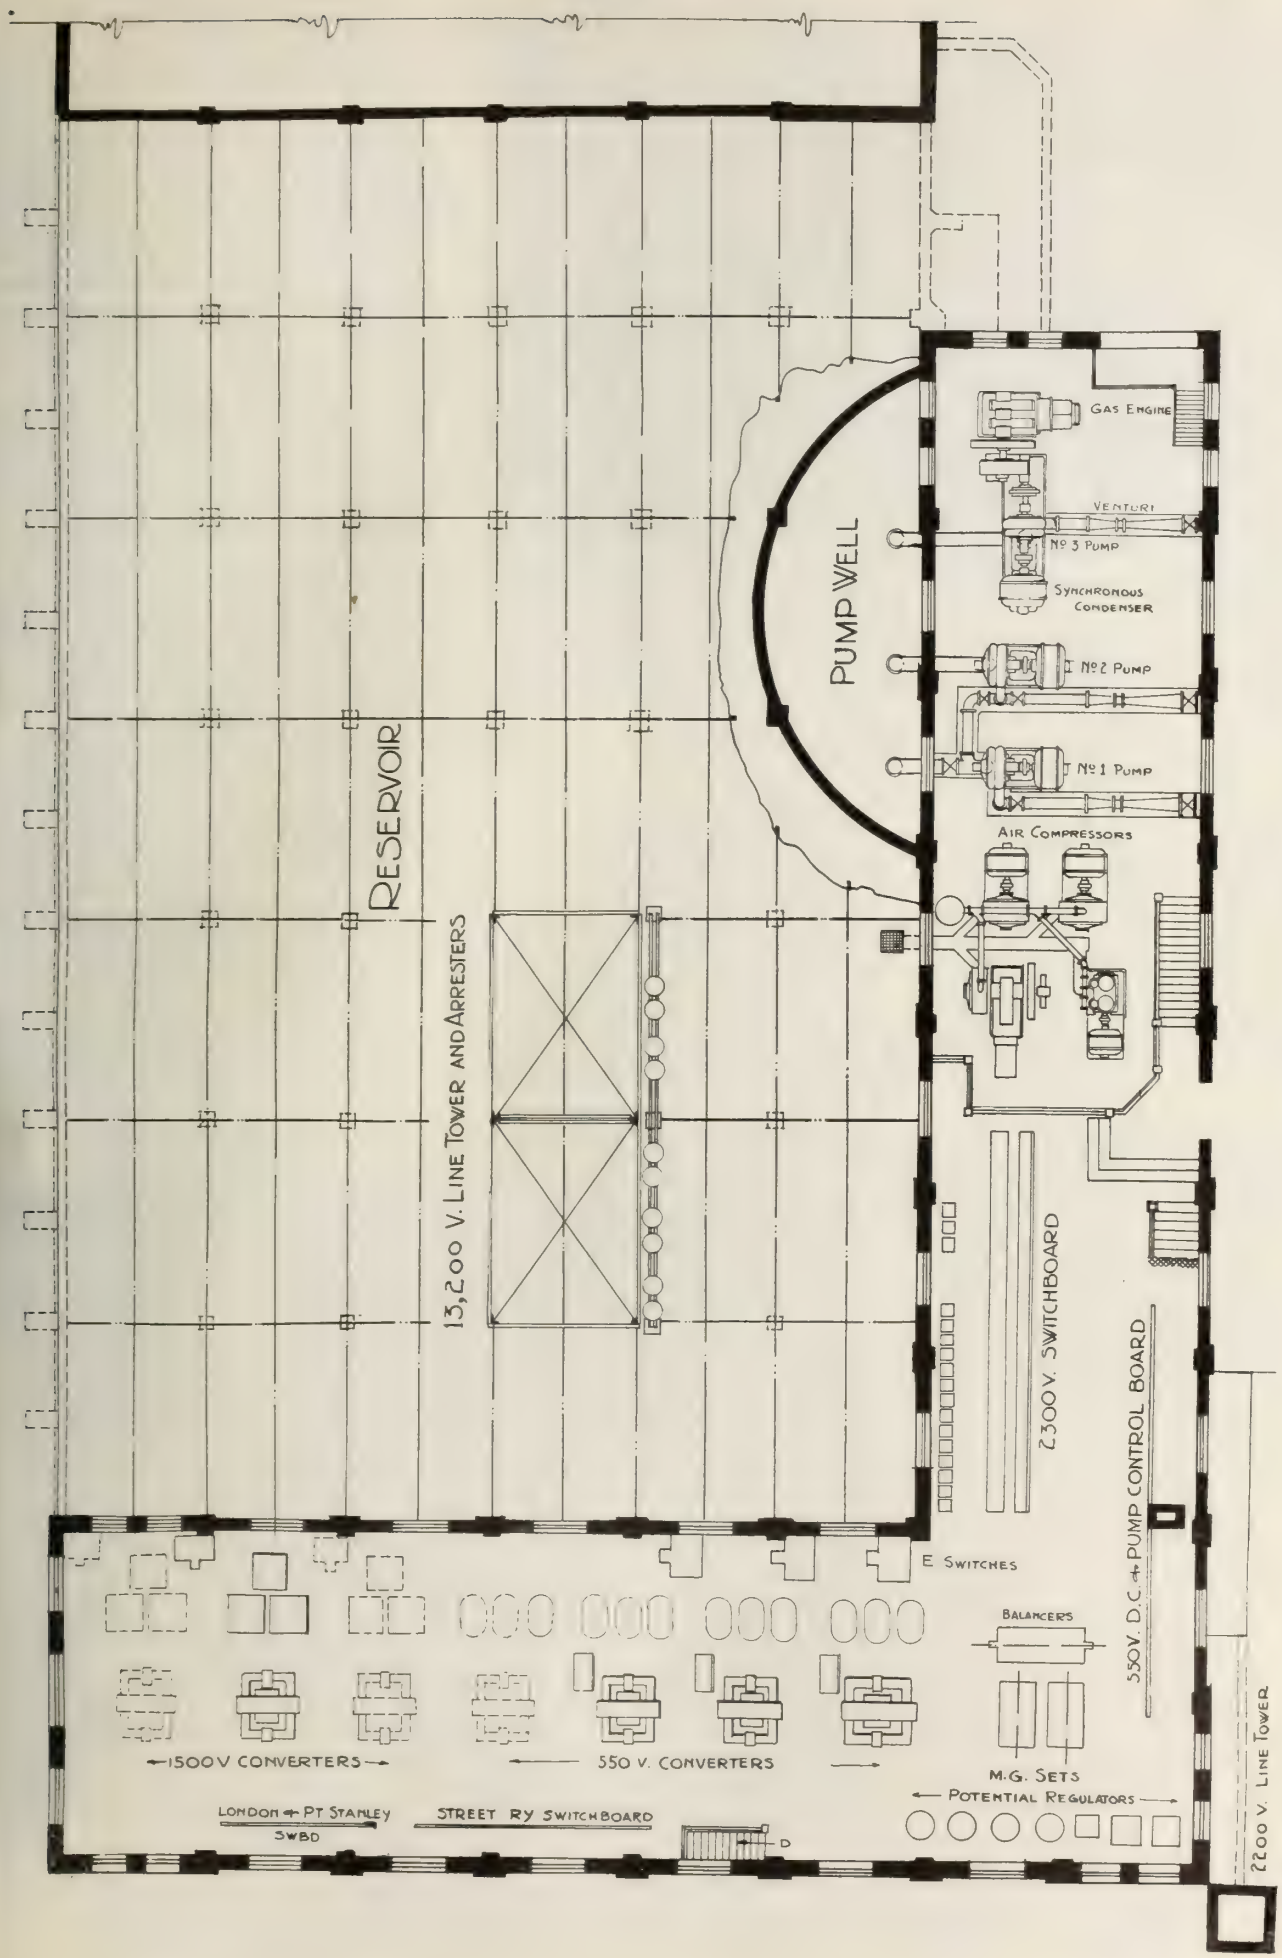
No. 1 and No. 2 pumps are driven by two synchronous motors of 200 h.p., manufactured by the Lancashire Dynamo and Motor Co. These motors take 3-phase current at 575 volts from the substation busses, and are started up as induction motors, this being accomplish-



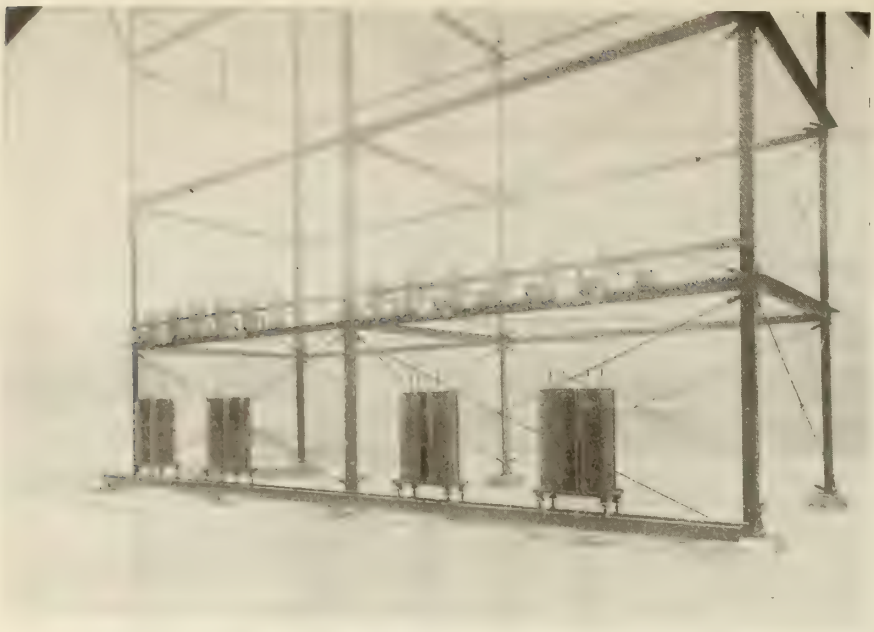
FOUR CYLINDER REAVELL AIR COMPRESSOR DRIVEN BY LANCASHIRE SYNCHRONOUS MOTOR.



BELLISS MORCOME AIR COMPRESSOR DIRECT CONNECTED TO C.G.E. SYNCHRONOUS MOTOR.



GROUND FLOOR PLAN OF THE RIDOUT ST. STATION OF THE LONDON PUBLIC UTILITIES COMMISSION. THIS STATION IS A COMBINATION OF WATERWORKS, PUMPING AND ELECTRICAL DISTRIBUTING STATION.



13,200 VOLT, LINE TOWER AND ARRESTERS.

ed by inserting resistance across the rotor slip rings. As the motor speeds up this resistance is gradually cut out and when up to synchronism the exciter is cut in and the exciter current adjusted to the proper value.

These two pumps are arranged in such a manner that they can be connected up in either series or parallel so as to obtain either the normal operating pressure or 140 lbs. for fire purposes.

While the third pump is similar to the other two it is driven either by a two cylinder gas engine or by a synchronous condenser which under normal conditions is run solely for power factor correction. The gas engine is of the four cycle type, manufactured by T. H. and J. Daniels, of Stroud, Eng. The cylinders are 15¼ in. dia. by 23¼ in. stroke, and the flywheel is 6 ft. 10¼ in. dia. When running at its usual speed of 175 revs. per min. the engine has a horsepower of 150.

A set of enclosed gears serves to transmit the power to the turbine pump giving a speed ratio of five to one and a jaw clutch serves to disconnect the engine when it is desired to use the synchronous condenser as motive power.

Synchronous Condenser

The synchronous condenser mentioned above is of Canadian General Electric manufacture, type A. T. I., and is rated at 500 kv. a., with an operating voltage of 575. When run to capacity it takes a current of 502 amperes and affects a power factor correction of about 20 per cent. under average conditions on the station load. The turbine pump is connected to it by means of a Hill type jaw friction clutch.

The three pumps discharge directly into the city mains and their duty is measured by means of three Venturi meters of 12 in. throat located in the discharge pipes.

Air Compressors

The compressed air necessary for the operation of the air lift pumps is supplied by several air compressors located in the Ridout St. station. Three of these compressors were built by Reavell and Co., Ipswich, Eng., and have four cylinders arranged at 90 degs. around a common crank shaft. This results in an exceedingly compact arrangement well adapted to the compressing of air economically. Two of these pumps have 14½ in. diameter cylinders, 4 in. dia. connecting rods, 6⅞ in. stroke, and are of the single stage type with 10 delivery valves in each cylinder. When driven at 250 revs. per min. by 100 horsepower synchronous motors they have a capacity of 500 cubic feet of free air per minute. The motors used are similar in type to those directly connected to the pumping units and were also built by the Lancashire Dynamo and Motor Co.

The third Reavell compressor is of the same type and general dimensions as the other two but has 15½ in. cylinders and is driven by a T. H. and J. Daniels gas engine at 200 revs. per min. This compressor has also a capacity of 500 cub. ft. per min. The gas engine is of the four cycle type of 110 h.p. The cylinder is 17 in. dia. by 27 in. stroke and the flywheel is 7 ft. diameter.

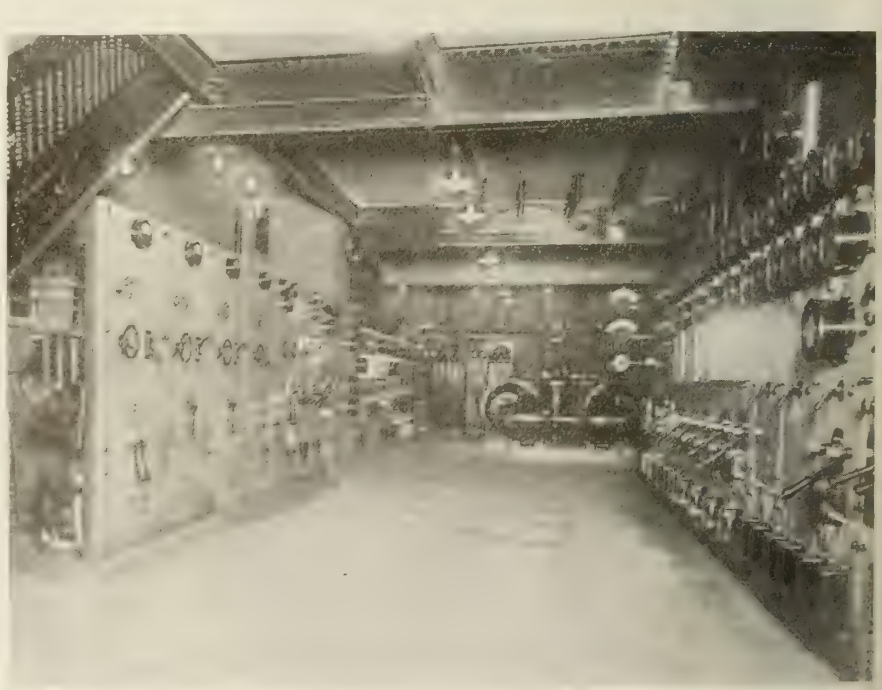
It will be noticed that gas engine drive is provided for one pump and one air compressor. This has been done in order to provide a reserve feature in the event of power failure.

The fourth air compressor is a Belliss and Morcomb two-cylinder single stage vertical compressor, in general features closely resembling the well-known high-speed engines of similar make. The cylinders have a diameter of 16 in. with a stroke of 14 in., and when running at 375 revs. per min. the compressor delivers 710 cub. ft. of free air per minute at 30 lbs. pressure. This unit is driven by a direct connected C. G. E. synchronous motor of 165 horsepower taking current at 575 volts from the station busses.

The Electrical Installation

The electrical installation at Ridout St. station has been developed from the original equipment installed when Hydro power was first made available in London. This original equipment was located in that part of the station now known as substation No. 1, the street railway and Port Stanley equipment being placed in a later addition known as No. 5 substation.

Power is received from the transformer station of the Hydro-Electric Power Commission about two miles distant through three 13,200 volt, three-phase 25 cycle feeders. These feeders dead-end on a high tension distributing tower



GENERAL VIEW OF SWITCHBOARDS MOTOR-GENERATOR SETS AND POTENTIAL REGULATORS.

shown in the accompanying illustrations. On this tower are also mounted the five sets of 13,200-volt Canadian Westinghouse lightning arresters which protect both the incoming lines above-mentioned and the two outgoing feeders, one of which supplies the Springbank plant and the other several of the smaller transformer houses located in the districts where the demands for power are unusually heavy. The horn gaps for these arresters are also located on this tower.

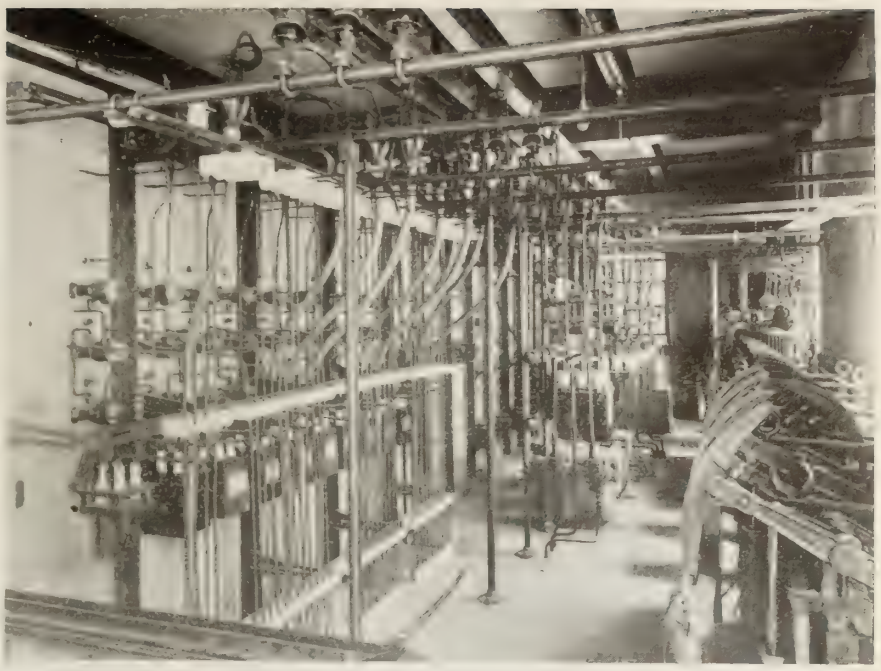
Switch Structure

From the tower the 13,200-volt lines pass into the station through wall bushings protected by a hood. Westinghouse potential transformers are provided on the incoming feeders for the metering of the load. Choke coils are provided on all feeders and disconnecting switches serve to isolate the incoming lines from the station busses to which they are directly attached, no oil switches being provided as the incoming feeders are controlled from the other end.

The high tension switching equipment is mounted in a concrete switch structure and type E Westinghouse remote-controlled solenoid-operated switches are installed throughout on all the 13,200-volt outgoing feeders and the high-tension side of all transformers, the E switches for the rotary converters being placed adjacent to the machines which they control on the main floor.

2,300-Volt and 550-Volt Feeders

Six outgoing 2,300-volt three-phase feeders are provided for serving the residential and other lighting requirements, as well as the lighter 110 volt power demands of the city. The 2,300-volt current is stepped down by means of the usual pole-type transformers and is locally distributed at 220/110 volts by means of a three wire system.



VIEW BEHIND 2300 V. SWITCHBOARD, SHOWING BUSSES AND SERIES LIGHTING TRANSFORERS.

These feeders are regulated by means of six G. E. 3-phase potential regulators. One 2,300-volt three-phase power feeder is provided and is also regulated by similar apparatus to that used on the lighting feeders.

The above 2,300-volt distribution system is energized by means of three delta-connected banks of single-phase Canadian Westinghouse 13,200/2,300-volt oil insulated, water-cooled transformers.

550-volt alternating current power is supplied through the medium of four three-phase feeders unregulated, and for these feeders six single-phase transformers, also of Westinghouse make, are provided. These transformers also supply the 550-volt power load of the station itself, including that necessary for the synchronous motors and condenser in the pump room.

INTERIOR VIEW SHOWING STREET RAILWAY ROTARY CONVERTERS AND D.C. SWITCHBOARD.

Transformer Arrangement

The two sets of transformers above-mentioned are located in the basement and are provided with wheeled bases, running on tracks sunk in the floor. When it is desired to remove any transformer it is rolled on the tracks to the center of the bay and placed on a truck fitted with rails aligning those in the floor. This truck runs in a pit provided with rails and conveys the transformers to a location where they can be picked up and handled by an eight ton hand-operated crane. The pit during normal times is covered by checkered plate flooring cut into convenient sections for ready removal.

Two three-phase 1,500 kv.a. transformers of Canadian General Electric make are located in the new wing of the sub-station and these also supply the 2,300-volt lighting feeders.

D. C. Power

A certain amount of direct current load is carried by this station in addition to the street railway and the London and Port Stanley Railway requirements, and to take care of this load four three-wire 550 225-volt feeders are required.

For this direct current service two motor generator sets are installed. The generators are of 70 kw. each and are of the Westinghouse three-wire type, the neutral wire being connected to the neutral balancing coils by means of slip rings on the end of the armature shaft. These generators are driven at 675 revs. per minute by means of two alternating current 550-volt, 120 horsepower, three-phase Lancashire motors. A balancer set is provided for use when the motor generator sets are not available, in which case the supply is taken from the 550-volt rotaries supplying the street railway load. This balancer set consists of two Westinghouse type S motors direct connected and of 40 h.p.

Switchboards

Two switchboards are provided in the No. 1 substation, controlling all circuits except those connected with the rotary converters.

The main switchboard controls the 13,200-volt incoming lines, and the 2,300-volt outgoing feeders. The 13,200-volt switches are remote controlled and for this purpose the usual control switches and indicating lamps are provided. The 2,300-volt lighting and commercial feeders are all controlled by means of type B Westinghouse switches mounted on a separate pipe framework at the back of the board and serving also to carry the 2,300-volt busses.

The 2,300-volt series street lighting circuits of which there are sixteen are also controlled from this board, single-phase type D switches being mounted directly on the marble panels for this purpose. From the switches the street lighting feeders run to the constant current regulators or transformers, seven of which are of Adams Bagnell make and the remainder Canadian General Electric. These sixteen feeders carry a total of 4,827 series street lamps of 75 watts each.

All 2,300-volt feeders leave the switchboard through porcelain bushings in the floor and are racked on the ceiling of the basement to the distributing tower up which they are carried in lead-covered cable to standard underground potheads for connection to the overhead lines.

All circuits are provided with inverse time limit relays and with the usual indicating ammeters, all of Westinghouse make. The incoming 13,200-volt lines are provided with graphic wattmeters for totalizing the station load.

The second switchboard is located directly opposite the first one and controls the station pumping and compressor equipment. Six panels are provided for the pump and compressor motors and are all equipped with starting rheostats and switching equipment, exciting current control and ammeters. One panel is allocated to the two exciter units which are located on the pump floor. These units consist of 60-volt, 500 ampere 1,440 revs. per min. shunt-wound generators direct connected to 575-volt three-phase motors, all of Lancashire make.

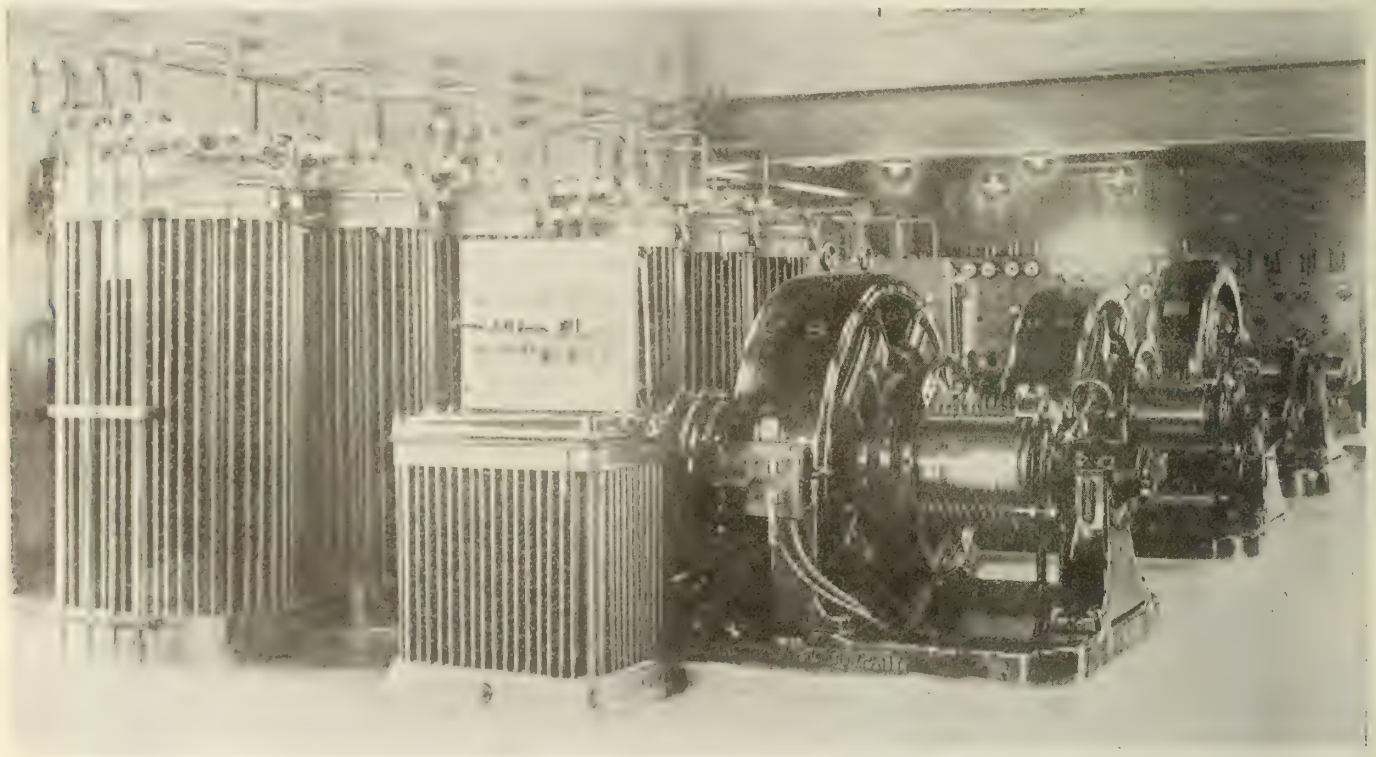
Station Service

The station switchboard panel is located on this board and contains the usual station lighting switches and motor generator and battery control. The lighting circuits have all been arranged for either alternating or direct current operation, and in case of trouble or power failure can be readily thrown on the station battery. The electric control for the type E switches and the relay and tripping circuits of the 2,300-volt feeder switches are of course all operated by the station battery.

An instrument panel forms part of this board and is given over to various indicating and recording instruments. Two panels are provided for the 13,200-volt outgoing sub-feeder.

The 550 alternating current volt power for the operation of the pumping plant and for outside feeders is all taken off a set of bus-bars at the rear of the board and the transformer and feeder panels form part of its equipment.

The 550/250-volt direct current requirements are met by four feeders which with the control for the motor



550 VOLT ROTARY CONVERTOR EQUIPMENT, C.G.E. CONVERTORS, TRANSFORMERS AND REACTANCES.

generators and balancer set occupy two panels.

D. C. Railway Equipment

The power necessary for the operation of the London street railway is furnished by this station, three 500 kw. Canadian General Electric rotary converters being provided. These machines are fed from the 13,200-volt busses, type E, oil switches being provided for their isolation. The rotary transformers are located immediately behind the rotaries which they feed and reactances are provided for better voltage regulation. The transformers are single-phase, oil insulated water-cooled, and those for one rotary are delta connected, giving the phase current while the other two rotaries and transformers are connected six phase. As will be seen from the illustrations the starting and field break-up switches are mounted immediately above the reactances which are of 45 k.v.a. rating.

The street railway switchboard is of the usual type, machine control, and feeder panels being provided, with the usual ammeters and circuit breakers. Volt meter plugs are provided for the reading of the feeder voltages on a Weston voltmeter bracketed on the end panel.

Thompson switchboard-type integrating wattmeters are provided for totalizing the load and a Westinghouse graphic wattmeter records the fluctuations in the power required.

London and Port Stanley Equipment

Owing to the length of the road and the distance between sub-stations a voltage of 1,500 was chosen for the operation of the London and Port Stanley road.

The London end of this system is taken care of by the Ridout street station, a 500 kw. Canadian General Electric 1,500-volt rotary converter being provided. This rotary also has its own type E oil switch and transformer and is supplied with a Westinghouse starting panel with a type B double-throw oil switch for the starting and running positions and a similar switch for the field breaking. This panel is mounted near the machine and is separate from the main switchboard which is provided with hand-operated oil switches instead of the usual knife type on account of the high voltage carried.

GRAPHITE IN OIL

IN preparing mixtures of graphite and oil for lubricating purposes, it was for a time thought essential that the graphite should be ground to the utmost practical degree of fineness in order that it might remain suspended in the oil without any tendency to settle by gravity or choke the passages of the lubricators, and in pursuit of this aim, methods of preparing graphite were evolved capable of giving a powder in which no particle exceeded 1-250,000 in. in diameter.

When, however, such fine particles are mixed with oil, a curious phenomenon is observed. The particles begin spontaneously to coalesce, and when the mixture is examined under a powerful microscope, it is seen that the particles are in perpetual zig-zag movement through the oil. The explanation, as given by the Brownian hypothesis, is that the movement is due to the particles of graphite being struck by free electrons, whereby a particle, in being struck, starts with a jerky movement, and continues moving until arrested by the fluid friction of the oil, provided it has not already been struck by another electron, causing it to bound off in another direction.

During these erratic movements the particles of graphite collide with each other, and, as a result, adhere; they in turn are struck by other particles, and in this manner there is gradually built up a mass of adhering particles which is subject to the action of gravity, and results in settling out. Various expedients have been resorted to in order to negative this tendency. The one most commonly made use of is that of coating the finely-ground particles with a foreign substance and then effecting a high dispersion of those coated particles throughout the oil.

The coating material is usually a vegetable compound, such as castor oil, or it may be tannic acid or an allied tanning compound. By these means the permanent suspension of the ultra fine graphite particles in oil has been successfully achieved, but of late the question has been raised whether this extreme fineness, to the securing of which so much effort has been directed, does not of itself render the graphite ineffective.

It is to be borne in mind that in the bearing properly constructed, lubricated, and in operation, the bearing surfaces are completely separated by the oil film, and the particles of graphite simply float in the film, exerting no appreciable effect, either beneficial or otherwise. In such a bearing the graphite is not intended to play any part, its role begins when, for any reason the oil film between the bearing surfaces is destroyed. Then, as the oil film is squeezed out, the graphite particles are carried along with the oil from between the bearing surfaces until the film is reduced to a thickness corresponding to the dimensions of the largest particles of graphite, which at this stage will be arrested and held between the surfaces. Upon the complete destruction of the film these particles so held are crushed and embedded into the grain and pores of the surfaces, and thus are made to perform their function of solid lubrication.

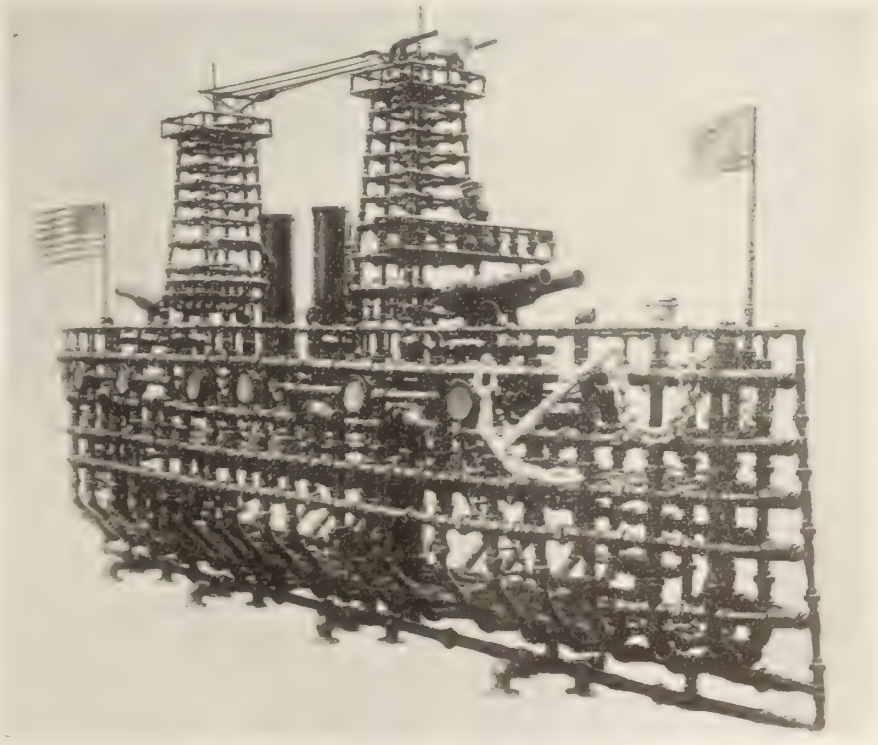
A BATTLESHIP OF PIPE FITTINGS

By K. C. P.

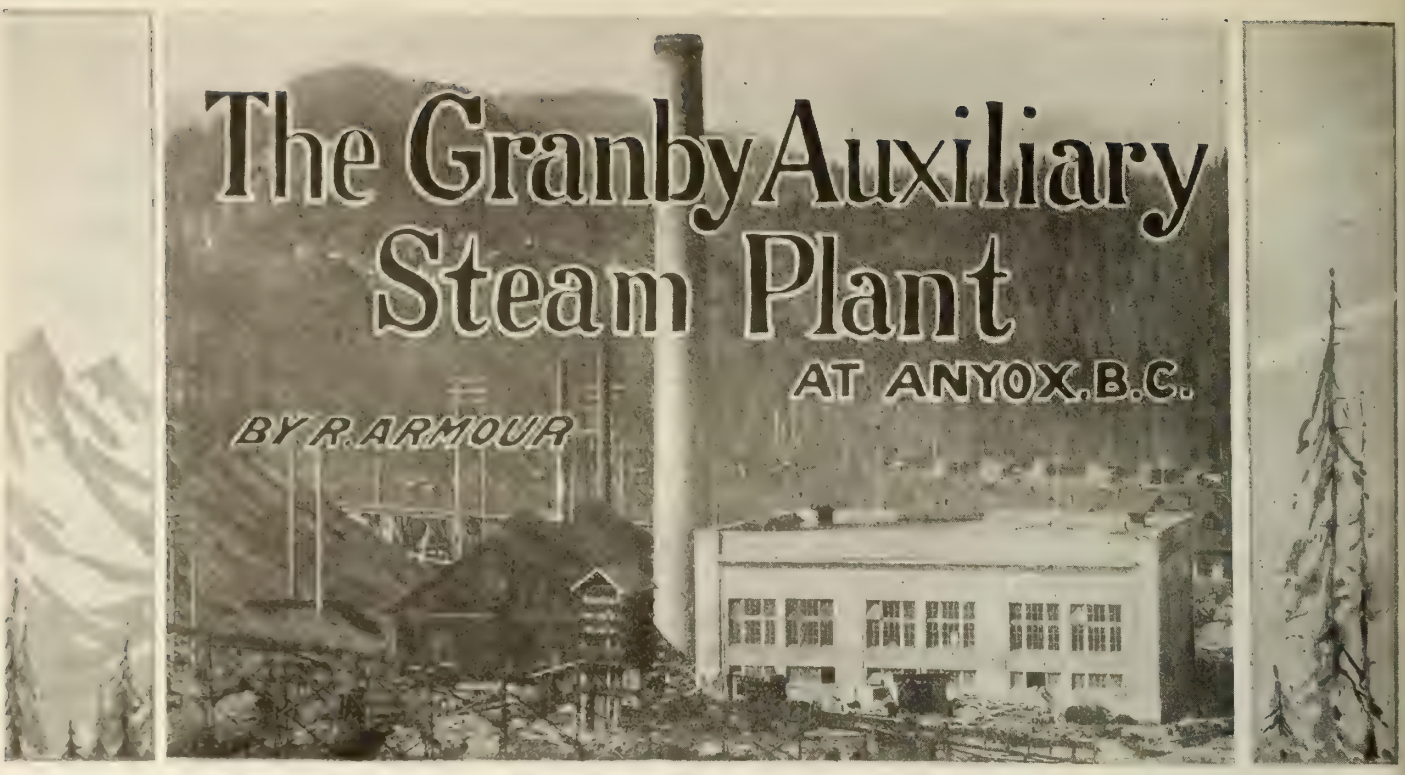
THE accompanying illustration shows the model of super dreadnought "New York," made entirely of pipe fittings and valves of a Chicago manufacturer.

It is of interest to note that the model has a length of 186 inches, a breadth of 34 inches, and a molded depth of 42 inches, the total height from keel to top-mast being 102 inches, while its net weight is 3,308 pounds. Six thousand six hundred and sixty-nine separate parts enter into its construction. It is complete to the smallest detail, and the ordinary working parts of a battleship are movable.

There is a small electric motor which gives action to the propeller. This ship is electrically wired throughout, the wires running in conduit, and by the pressing of a button action may be seen everywhere; the propeller turns, the commander salutes, lights flash, guns roar, the wireless crackles, the searchlight throws a searching beam. The entire action is automatic and may be repeated indefinitely or until the pressing of another button stops it.



BATTLESHIP MADE ENTIRELY OF PIPE FITTINGS.



PART II.

The many uses for power in the various metallurgical operations connected with the refining of metals necessitate more than usual provision for adequate and unfailing supply. The following article deals with the steam plant auxiliary of one of the largest smelters in British Columbia.

NO. 1 main unit is a 3,750 k.v.a. Westinghouse turbo-generator, the steam turbine and generator being direct connected and running at 3,600 rev. per min. The generator is 3-phase, 60 cycles, 2,300 volts, the machine being entirely enclosed in a casing, with fans on either end of the rotor blowing air into the centre of machine to keep the winding cool.

Turbine

This turbine is of the impulse reaction double flow type, that is the steam acts first on small impulse blades, at the middle of the machine and then on the other blades which get larger toward the ends and finally exhaust at both ends of the machine into the condenser. This machine like most high speed turbines is fitted with an operating governor and a safety stop governor. The safety stop is much the same as that described under feed pumps. The main throttle valve is a balanced valve having steam pressure top and bottom of a piston within the valve itself. The steam from the bottom of the valve is pined to the bottom of safety stop and if the machine should run over a predetermined speed, in this case about 4,000 r.p.m. the safety will trip, thus allowing the steam pressure on the bottom side of the throttle valve to exhaust to atmosphere when the throttle valve immediately closes, to its seat, being closed by the steam pressure on the top side of piston within the throttle valve. Before the safety trip can be put back into place the throttle valve must be screwed down to its seat. In this way it makes the machine safe, for if it were possible to put the safety stop back to place with the throttle valve wide open, steam would be turned into the machine the full bore and pressure in the pipe. In a word, this automoatic throttle makes it fool proof. When starting the machine again, the throttle must be opened very slowly and when the machine is up to speed so that the governor has control, the valve can be opened wide and the governor will then take care of the regulation of steam.

The condenser on this machine is much larger than is necessary, with conditions here. This entire unit was purchased from the Havana Electric Light & Power Company, Cuba, through the Westinghouse Co., as it was impossible for them to furnish the Granby Co. with a suitable generator at the time on account of the large number of orders on hand. The condenser is a Wheeler surface condenser and was made to suit the condensing water at Havana which has a fairly high temperature, about 85 degs F., as compared with our average temp. here of 36 degs. F.

Previously this condenser was taking the circulating water in at the top and discharging at the bottom. This arrangement allowed the exhaust steam which enters from the turbine at the bottom of condenser to strike the hottest water in the condenser first, which results in more equal expansion of the tubes; this was rather detrimental in this case, for if the circulating water stopped for any reason, the water in the condenser would drain out; so the connections were changed and since have given no trouble such as occurred at first. Considerable trouble was also due to other causes, principally to the failure of the circulating pump. The circulating pump is located at No. 1 power house and is motor driven, the pump taking the water from the tail race of the water turbines. As this water is highly charged with air and the suction lift fairly high, probably 16 or 18 feet, the pump occasionally becomes air-bound and loses its priming. The condenser has 4,020 tubes, three-quarter inch diameter by 18 feet 2 inch long, and has an approximate cooling surface of 14,800 sq. feet, though half this surface would be quite sufficient under present conditions. There is one thing about condensers which engineers in British Columbia must bear in mind; that is, between the turbine or reciprocating engine and condenser there must be an automatic relief valve to the atmosphere and, by having a stop valve near condenser in the event of trouble to the condenser this stop valve can be closed and engine can exhaust to atmosphere until condenser repairs are made.

In the No. 1 unit the stop valve between the steam turbine and condenser is a 48-inch gate valve and the automatic relief to the atmosphere is an 18-inch valve. There is a considerable difference in the size of these valves but in the

larger one the steam pressure is only about 1 lb. absolute, while in the smaller valve the pressure might be about 40 lbs. gauge or 55 lbs. absolute. The circulating water pipes to the condenser are 12 inches diameter.

The auxiliaries consist of a Terry steam turbine of about 100 h.p., and direct connected to the air and hot well or condensate pumps. There is space on the bed plate for a circulating pump, but it is being used at No. 1 power house to supply the condensers with water.

The condensate pump is fitted on one end of the turbine, and is a Wheeler pump of the ordinary centrifugal type. This pump is set lower than the condenser so that the water may flow by gravity into the pump. The suction pipe is 4-inch and the discharge pipe 3-inch. There is also a 2-inch equalizing pipe which connects to the side of the condenser near the top at one end, the other end of the pipe connecting to the suction side of condensate pump. This pipe equalizes the pressure on the top and bottom of the condenser and allows water to flow freely into the pump. The discharge from this pump goes into the feed water heater in the boiler room and the exhaust steam from the steam turbine driving these pumps also enters the feed water heater and raises the temperature of feed water before entering boiler.

Air Pump and Oiling System

A Thysen air pump, of the centrifugal type, supplied by the Wheeler Condenser Co., is installed. Directly beneath the pump is a concrete sump or well about 8 ft. long by 6 ft. wide and 6 ft. deep. This sump is divided into two compartments by a wall about 30 in. high. The air pump draws water from one side of the sump and discharges it into the other, a continuous circulation of water being maintained through a screened opening.

The air pump suction is provided with a foot valve. As the water is used over and over again it, in time, gets warm and a 3 in. make-up line is provided, the overflow being taken care of by a line running to the sewer.

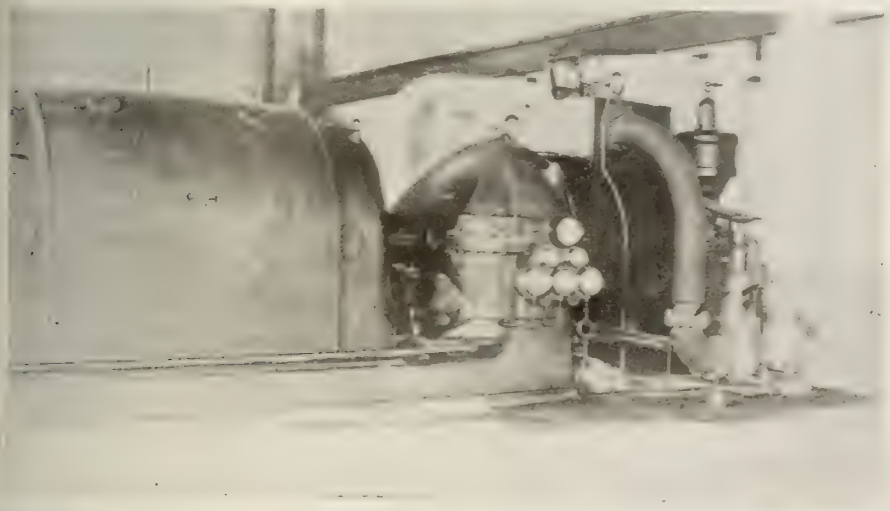
The pump runs at 1,600 revs. per min., and draws the air from the top of the condenser, discharging it along with the circulating water into the discharge side of the well. The air pipe is 7 in. diameter.

A 3 x 2 x 3 in. duplex oil pump is provided for each turbine unit about 4 to 5 lbs. oil pressure being maintained on the turbine and generator bearings by this means when starting up. When the machines are running centrifugal pumps on the turbines provide the necessary oil pressure, an oil cooler serving to carry away the heat. The oiling system of No. 1 unit holds about two barrels of oil and that of the No. 2 unit about one and one half barrels. A special grade of oil is used.

Gauges

There is a gauge board on each turbine with a number of gauges. One gauge shows the steam pressure on boilers, another the pressure of the steam turbine which varies according to load. A vacuum gauge is also provided, although the machines are also fitted with mercury columns which give a more accurate reading, the vacuum gauges going out of working order easily. There is also a gauge to show the pressure of oil on bearings which runs about four or five pounds. A gland gauge is provided showing the pressure of water on the glands at each end of the turbine, about 5 to 6 lbs.; this water pressure seals the glands so that air cannot enter into condenser and without this seal a good vacuum could not be maintained. There is also a vibration tachometer or speed gauge which shows the speed at which the turbines are running and when running on load the speed in this case is 3,600 rev. per min.

GENERAL VIEW OF TURBINE ROOM WITH SURFACE CONDENSER IN BACK GROUND.



NO. 2 TURBO GENERATOR INSTALLATION 2500 K.V.A. WESTINGHOUSE GENERATOR AND TURBINE.

No. 2 Unit.

This machine is a 2,500 k.v.a. Westinghouse turbo-generator delivering 2,300 volt 3-phase 60-cycle current. This turbine is of the impulse reaction single flow type, that is the steam enters at one end of machine on the small blades, goes through each stage of the blading and enters the condenser from the other end of turbine. As far as operation goes this machine is practically the same as the No. 1 unit except that No. 1 unit has a relay on governor making it more sensitive, while No. 2 machine has a centrifugal governor without any oil relay. This is a new machine recently installed. There is considerable vibration from the No. 1 unit, but this is entirely absent in No. 2 unit.

Clearances

The high economy which these machines produce is due principally to the small steam clearances. Great care is required in the actual adjustment of the rotating blades. This is done by having a thrust block with a number of grooves turned in the shaft and rings on the bearing which fit into these grooves. The upper and lower halves of the thrust block can be adjusted separately by micrometer screws, with dials to show the exact positions of the blades. If the up-

NO. 2 TURBO-GENERATOR UNDER CONSTRUCTION. GENERAL VIEW.

per half of the bearing tends to press the shaft to the right, then the lower half will tend to press the shaft to the left. These clearances are about 10-thousandths of an inch and the machine is arranged so that the gland runner and its casing will be the first to come in contact, thus partially protecting the blades.

The clearances between the end of the blades and the steam cylinders of the turbine, or the radial clearance, runs about 35 thousandths of an inch. The adjustment for radial clearance is made by having four pads on each bearing top and bottom and both sides. Under these pads are liners of known thickness and liners are taken out or put in until the blades give a slight rub when turning over by hand. After the blades have given a slight rub on one side liners of .030 or .035 of an inch thickness are put in under the pad on the side where the rub occurred. By this means the clearance is known exactly. Top and bottom and both sides of every bearing is adjusted in this way and a careful record of setting of these bearings ought to be kept.

Condenser. No. 2 Unit

This unit is fitted with a Westinghouse La Blanc jet condenser. The air pump works on the same principle as the air pump described for No. 1 unit. The auxiliaries of No. 2 unit, that is the air and hot well pumps, are driven by a small Westinghouse steam turbine running at 3,600 rev. per min. A set of enclosed reduction gears running in oil is provided between turbine and pumps and water is passed through a coil in the oil to keep it cool. The slow speed shaft of the gears is attached to the shaft of air and hot well pumps, the pumps running 72 rev. per min. In this way high steam economy is obtained from the steam turbine and the pumps are run at a suitable speed. The exhaust steam from the turbine exhausts into the exhaust steam header and this header as before mentioned carries the steam to feed water heater. The steam pipe to turbine is 2½ in., and the exhaust 4 in., with a copper expansion joint on the exhaust pipe close to turbine. The water pipe on the suction of the air pump is 6 in., with a foot valve on the end of the pipe in the sump. The discharge pipe from the air pump is 5 in. pipe, and of course goes back into air pump sump. The water pump has 6 in. outlet. The injection water is carried into the condenser by a 9 in. pipe, the regulating valve being close to condenser and an extension handle passing up through the floor so that any changes in the amount of injection water can be made either from the basement or the main turbine room floor.

There is a vacuum breaker fitted to this condenser so that if water rises too high in the condenser or the vacuum is lost, the vacuum breaker valve will open and trip the lever of the butterfly valve on the injection line, thus completely shutting off the injection water entering the condenser, the atmospheric relief valve will then open and the turbine will exhaust to the atmosphere. All pipes to the condenser, injection inlet and outlet, air pump inlet and outlet, and the exhaust steam from turbine are fitted with metal tubes to hold a thermometer, so that temperature of the steam or water passing can be easily taken at any time. There is a vacuum gauge connected to the air pump suction and one on the condenser close to the pump so that when adjusting the pump it can be seen just what changes are occurring.

The gauge on the pump suction is run at about 10 in. vacuum. These gauges are in addition to the gauges provided on the gauge board in the turbine room, which contains steam inlet, vacuum, gland, tachometer or speed gauge and bearing oil pressure gauges. Between the turbine and condenser there is a copper expansion joint the full size of low pressure exhaust opening into condenser this being 30 in.

There is a 16 in. atmospheric relief valve which opens if vacuum is destroyed and allows turbine to exhaust to atmosphere through a 16 in. exhaust pipe. The high pressure steam pipe to this machine is 6 in. dia.

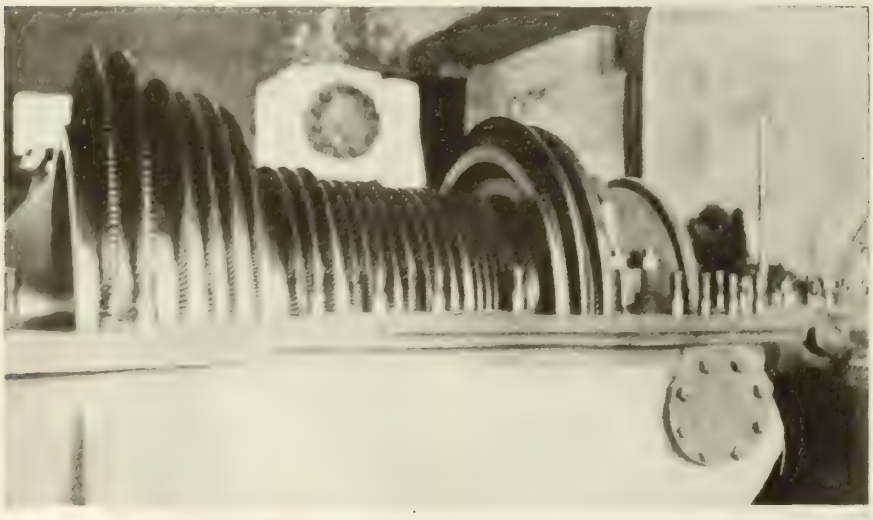
Exciter Unit

The exciter unit consists of a Westinghouse steam turbine direct connected to a 100 k.w. Westinghouse d.c. generator running at 1,800 rev. per min. This machine supplies exciting current to No. 1 and No. 2 generators, an alternative course of exciting current being furnished by an exciter at the No. 1 power house. The turbine is fitted with a governor of fly-ball type enclosed in a casing and also with a safety stop arrangement which works on the same principle as provided for the generators.

The exciter unit steam line is a 4 in. pipe and the exhaust is a 12 in. pipe, a 12 in. copper expansion joint being fitted on the exhaust between the turbine and exhaust header. The exhaust of this machine also goes to feed water heater. There is a 12 in. valve on exhaust line between turbine and main exhaust header.

No. 3 Unit

No. 3 unit is a De Laval Rotary air compressor and is still under construction. In this machine we have a 1,000 h.p. steam turbine on one end, the compressor in the centre and direct connected to the turbine. and an induction motor on the other end. By this arrangement the compressor can be run either by steam or motor. There is a set of re-



NO. 2. TURBO-GENERATOR UNDER CONSTRUCTION SHOWING TURBINE BLADING.

duction gears between the compression and the motor, the turbine and compressor running about 3,000 rev. per min., and the motor 70 rev. per min. The compressor has 14 stages, will generate air to 100 lbs. pressure, and has capacity of 3,500 cubic feet of free air per minute. The motor of this installation is a Westinghouse constant speed induction motor of 800 h.p., 3-phase, 2,200 volts, 190 amps. per terminal, 7,200 alternations per minute. The turbine of this machine is to have a Koerting jet condenser, the exhaust opening from turbine to condenser being 18 in., the steam inlet to turbine a 4 in. pipe and the exhaust to atmosphere will be a 12 in. pipe.

The makers claim high efficiency for this unit, the speed of the turbine being such as to secure good results. As a lower speed is essential in the motor, the reduction gears are fitted, the makers claiming 98 per cent. efficiency for the gears. Like the reduction gear already mentioned on the auxiliaries of No. 2 unit, the gear on this machine will be running in oil and the oil cooled by a coil circulating cold water in the oil chamber. The hot well pump for this unit is a De Laval centrifugal pump driven by De Laval steam turbine. The pump and turbine are direct connected running 2,800 rev. per min. The turbine has 2 in. inlet and 4 in. exhaust. The pump has 2½ in. inlet and outlet openings. The turbine is rated at 4 h.p. The hotwell pump will take the water from condenser and discharge it into the feed water heater. There is a 7 in. injection water line to condenser of this unit.

The feed water heater is a Blake and Knowles open heater rater at 3,000 h.p. The heater is 4 ft. 10 in. by 9 ft. long and 6 ft. 6 in. high. There are six doors heater, four of them large enough to take out the filtering pans, and two doors near the bottom of heater on the side for cleaning out. This heater has a series of perforated plates inside. The exhaust steam enters through a 16 in. pipe at the top and is broken up, going through these plates, then drops to the bottom of heater and mixes with the water. The water in heater then passes through charcoal and is filtered. The feed pumps are placed about 15 feet below the heater so that the hot water runs from the heater into the feed pumps. There is a 4-inch cold water make-up line with a regulating float valve for keeping sufficient water in the heater and the valve is set so that it will shut off when the heater is about 1-3 full. There is also a regulating float valve on 4 in. outlet from the heater to sewer and if water rises too high in heater this valve will open and allow water to run to waste. With the use of the feed water heater, the feed water is raised in temperature from about 100 degs. F. to an average of 200 degs. F. This heater has a 2½ in. safety valve and a 16 in. atmospheric relief valve.

Switchboard

The switchboard for this plant is comparatively small on account of all distribution being attended to from No. 1 power house, the switchboard consisting of only six panels. On the extreme right end of the board there are two swinging brackets, each bracket having two meters. The highest one carries the A.C. volt meters, with a range of 0-3000 volts. One of these meters shows the voltage on the main bus, and the other can be used on either No. 1 or No. 2 generators by means of plug switches on switchboards. On the other swinging bracket is the frequency meter showing the cycles and a synchroscope for using when generators are being put in on the line so as to get the machine being started running in synchronism with the machine already in service. This meter can be used for either generator by means of plugs on the switchboards.

Panel No. 1

The first panel is used for No. 1 generator. There is one a.c. ammeter which will show the current on any phase by means of plug switches on the board. On this panel is the power factor meter, also a direct current ammeter showing the field amperes or exciting current.

Panel No. 1.—The first panel controls the No. 1 generator. One a.c. ammeter serves to meter the load on any one-phase through plug switches. The field rheostat and ammeter are also mounted on this panel, and indicating and integrating wattmeters serve to meter the generator load. The generator circuit is privided with an oil switch mounted on the panel and provided with an inverse time limit relay which serves to trip the switch in the event of short circuit or other abnormal conditions.

Panel No. 2 is for the No. 2 generator, and has three alternating current ammeters, one on each phase of the machine. A kilowatt meter which shows the momentary load on generator in kilowatts and also a direct current ammeter show-

COMPOUND ENGINE AND TWO STAGE AIR COMPRESSOR. THIS PICTURE WAS TAKEN BEFORE THE ADDITION WAS ADDED TO THE NO. 2 POWER HOUSE.

ing the amperage the machine is taking for exciting purposes are provided, also a field switch and the main switch which is an oil circuit breaker, fitted with overload time limit relay. There are also synchronizing lamps and plug switches so that synchroscope and voltmeter can be used on this machine when starting up.

Panel No. 3 has a graphic meter which records on a paper chart the total load in kilowatts at all times, and it is from this chart that the maximum demand (which is the highest load for five minutes) and the maximum power (which is the highest load for fifteen minutes) are taken. The main kilowatt hour meter is also on this panel, this meter showing the total work done by both generators.

Panel No. 4 is only a small panel, having the direct current switch used for exciting purposes from No. 1 power house, this being used instead of running the steam exciter. On this panel is a signal lamp to the smelter to warn the smelter foremen in the event of a sudden shut down, so that arrangements can be made to clear the smelter furnaces, to avoid the coolin of the copper in the furnaces, when the air is shut off, for if the copper is allowed to cool in the furnace it must be removed later by blasting with dynamite.

Panel No. 5 is the direct current steam exciter panel, having ammeter and voltmeter, main switch, rheostat and a Thompson kilowatt hour meter showing the power used.

Panel No. 6 is for the De Laval rotary air compressor, and has an ammeter showing current taken by the motor. There are also three starting switches of an oil circuit breaker with overload time limit relay. A kilowatt hour meter shows the power taken by the motor to run the rotary compressor. There is a transformer in the basement directly under the switchboard from which the leads to the starting switches for the motor are connected.

In order to keep the exciter voltage uniform under changing load conditions a Tyrril regulator is provided on the extreme left end of the switchboard.

Future Unit

The turbine room has been laid out with a view to future expansion and for this purpose space has been left for another unit similar to those already installed.

The installation of heavy apparatus such as is found in the larger power houses is a difficult task without adequate provision for cranes, etc., and to facilitate erection a fifteen-ton crane has been installed. This crane is of Herbert Morris make.

A cold air duct is provided supplying air to the fans of the turbo-generator units. This air duct is 5 ft. square and draws in air from outside the building.

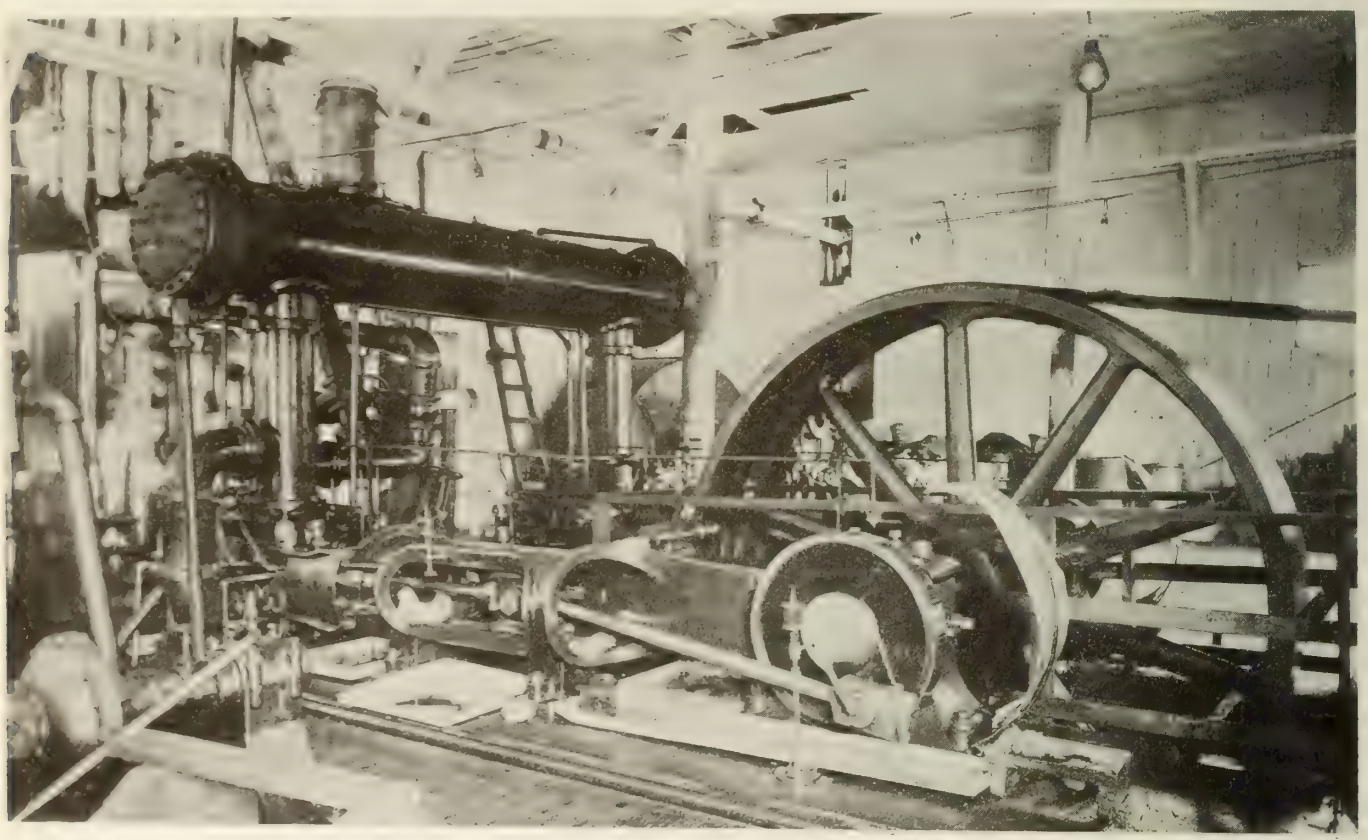
The No. 2 Power House Addition

An addition to this power house is under construction, much of the equipment of which is under operation at present.

Two boilers are being set up, both of the horizontal return tubular type, and of 175 b.h.p. combined rating. These boilers are being equipped with a Staples and Pheffer oil-burning system.

When completed these units will supply steam for heating, to the smelter concentrator and also to the boarding house and rooms. Approximately 1,000 men are served with meals at the Beach boarding house alone, and considerable steam is required for this purpose alone in addition to that used for laundry purposes, the boilers in No. 2 power house furnish this steam and are taking about three barrels of oil per hour. The uptake of these boilers will be the brick chimney used by the No. 2 power plant.

There are two air compressors in the building. The larger one is a Rand compound two-stage air compressor. The cylinders on the high side are steam 18 in., and air 20 in. dia. by 36 in. stroke, and on the low side the cylinders are, steam 34 in., air 32 in. x 36 in. stroke, running 86 revs. per minute. This machine was formerly run by steam, but the steam piston rods have been disconnected and the machine is now run by motor. The motor running this machine is a Westinghouse induction motor of 400 h.p. and takes current at 2,200 volts, 3-phase, 60 cycles. The motor speed is 290 revs. per min. at full load. The engine flywheel and pulley have fifteen grooves on their faces and are suited for rope drive. The rope used is 1½ in. The compressor is fitted with Corliss valve gear. The air is taken into this machine through the low-pressure cylinder, is compressed and then discharged into the intercooler, where the heat of compression is driven off by means of coils of pipe and cold water passing through coils. The air is then reduced in volume, and being under pressure a



CANADIAN RAND TWO-STAGE AIR COMPRESSOR. THIS COMPRESSOR IS DRIVEN BY A 200 H.P. WESTINGHOUSE MOTOR.

lot of moisture is taken out of the air and the air is then taken into the high-pressure cylinder where it is again compressed and passes out into the delivery line and into the air receivers. There is a safety valve on the inter-cooler so that if the pressure rises too high the valve will relieve the pressure.

The air passes from the receiver into the delivery line leading to the smelter and mine, and as the mine is about a mile distant a reheater is installed on the line. This consists of a form of small boilers where the air passing through the tubes is heated and absorbs some of the moisture in the air, thus keeping the air pipes from freezing, and dryer and better air is the result. This air compressor has a capacity of 33.34 cubic feet of free air per revolution, or 2,870 cubic feet of free air per minute. The air pressure carried is 120 lbs. The other air compressor to be installed in this building is at present running in a small frame building near No. 2 power house. This has 14 in. and 22 in. stroke cylinders and runs at 120 revs. per minute. There is a 200 h.p. Westinghouse motor driving this machine.

In the turbine room on a gauge board there is a Foxboro steam recording gauge which records the steam pressure on a chart for a 24-hour run. On the same board is a Foxboro pyrometer which records the temperature of the flue gases.

Venturi Meter

This meter stands about 6 feet high and has three dials. The top one is a recording gauge which records on a chart in thousands of pounds the amount of water passing into the boilers at any time during the day's run. The second dial is a meter which meters the amount of water going into the boilers in pounds. The third dial shows the momentary amount of water passing into the boilers in thousands of pounds per hour. This meter is made by the Builders' Iron Foundry, Providence, R.I.

CO_2 Recorder

This instrument is a Hay's CO_2 and draft recorder which records on a chart the draft and the percentage of CO_2 or carbon dioxide in the flue gases. This apparatus is a small laboratory in itself, and as the name implies, is automatic, and once started works well with very little attention, the charts being changed every twenty-four hours, and the caustic potash solution renewed once in three or four weeks. Flue gas analysis is quite a study, and something every engineer should know, but it is difficult to get any reading matter on this subject which is plain enough so that the average engineer can understand it. There are several good books by the inventor of this instrument, Jos. W. Hays and in his book, "How to Build Up Furnace Efficiency," he claims that the very worst smoke will not produce more than 2 per cent. fuel loss, while you can have as high as 40 to 50 per cent. loss by allowing too much air to enter the furnace and have no smoke. This has been proved in our plant here, for when the CO_2 recorder was installed at first the average CO_2 was 5 and 6 per cent. This was caused by having the stack dampers open too wide, and now 12 and 13 per cent. of an average CO_2 is being obtained and a great deal more work is being done with the same amount of oil.

The CO_2 recorder at this power house is placed at the end of the battery of boilers nearest to smoke stack. An inch pipe runs through the back ends of all boilers and a branch pipe is taken into this header from each boiler with a valve on the branch close to header. In this way a sample can be taken from any one of the battery of boilers. In order to get a good CO_2 percentage the fires must be good and only sufficient air admitted to burn the fuel as excess air is the greatest enemy in this respect. The brickwork of the boilers should be in good shape as the air leaks in brickwork will spoil your sample of gas, when good results are really obtained from the furnaces. The draft should be regulated by the stack damper for air leaks in the setting will still flow into the flue just as rapidly as ever if only ash pit dampers are regulated. When the stack damper is checked all draft to uptake is checked.

Plant Performance

In the foregoing pages it will be seen that the plant is well equipped with instruments so that performance of the plant can be seen at any time by going over the different recorded charts.

Jan. 15 to 31, 1918.

Average Load per day (average 24 hours)	
days)	62,000 K.W. Hours
Average Load per hour	26,000 K.W. Hours
Average bbls. oil per day (350 lbs. per bbl.)	310 bbls.
Average bbls. oil per hour	13 bbls.
K.W. hours generated per bbl. of oil	200
Fuel oil used per K.W. hour	1.75 lbs.

CHIMNEYS

By O. C.

THE boiler house chimney is a good example of that still lingering class of engineering contrivance which has to be proportioned by precedent rather than by abstract calculation. It would seem at first glance to be a simple matter to calculate what the height and area of a chimney should be to fulfil a stipulated set of conditions.

The composition and the volume of the furnace gases can be approximately foretold; the calculations of the velocity which such gases should have in a chimney of any given height appears to present few difficulties, the amount of air required for the complete combustion of a given amount of fuel is ascertainable, and from these figures it would seem that one ought to be able to say what minimum height and area of chimney will answer for the maximum requirements of any given plant.

It would be extremely convenient if this were so, for chimneys are costly affairs and there is no doubt that most chimneys are built somewhat too big for their job, and so cost more than, with more exact knowledge of chimney proportioning, would be necessary. But in fact all these simple calculations based on composition, temperature, volume, weight, and velocity are vitiated by the presence of uncertain and theoretically incalculable factors. Climatic conditions outside the chimney affect the temperature of the gases within and alter their weight and volume, and the chimney must be of such dimensions as to give a good average of efficiency between the extreme ranges of heat and cold, wind and calm. Air infiltration through the brickwork of the flues and of the chimney itself may materially affect the draught, and has to be reckoned with. The type of furnace and manner of firing and operation has an important influence on the amount of draught required at the furnace, and this is a factor that can be measured, but hardly calculated. The length and disposition of the flues leading from the furnace to the chimney base is another influence that can only be estimated by experience.

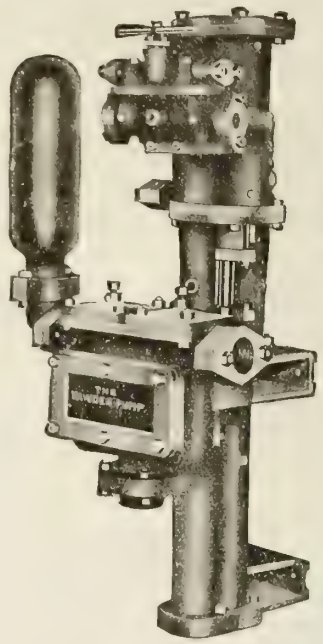
Because of these and other elusive factors the proportioning of a chimney is a matter of intelligent guesswork, based on a knowledge of the performances of actual chimneys serving plants of approximate type and size to the one under consideration. Naturally, in arguing from the imperfect actual to the perfect desirable, formulae can be used embodying constants based on ascertained data, and the chimney formulae found in engineering handbooks and textbooks are of this kind. Most of these can be relied on to give proportions for a chimney which will be adequate, but many of them give figures which allow in particular instances an unnecessarily large margin of capacity, being based on assumptions which under modern power house conditions no longer hold good.

Canadian-Built Centrifugal Pumps of Modern Design

Canadian Industrial Developments Demand High-grade Apparatus—Steam, Electric and Gasoline Driven Pumps Are Features in Product of Pump Building Concern

FOR some years the Bawden Pump Co., Ltd., Toronto, have been manufacturing steam and centrifugal pumps which have proved very successful. They have made extensive investigations of the duties required by pump users and in order to meet these duties have developed a full line of pumps of all types which embody some interesting features the particulars of which will be noted below. The centrifugal pumps are designed for general purposes such as water works, sewage disposal, fire service and boiler feed.

The company has also developed a complete line of pumps for heavy duties met with in pulp mills, such as handling pulp stock, chlorine liquor and acids, etc. Due to these heavy duties and the demand for a high class pump for this class of work, they have made a special study of the requirements of the pulp mill, and have accordingly developed a pump specially suitable to this work, and a few of the more recent installations are included in the following: Abitibi Power and Paper Co., 4 pumps; Port Arthur Pulp and Paper Co., 15 pumps varying in capacities up to three million gallons per day; Whalen Pulp and Paper Co., 16 pumps varying in capacity up to three million gallons per day; Frasers Ltd., 14 pumps varying in capacity up to four million gallons per day; Bathurst Lumber Co., 6 pumps varying in capacity up to four million gallons per day. They have under construction all the steam and centrifugal pumping equipment for the new Parliament Buildings at Ottawa, as well as a five million gallon high lift turbine booster pump for the city of Toronto.



MARINE TYPE BOILER FEED PUMP.

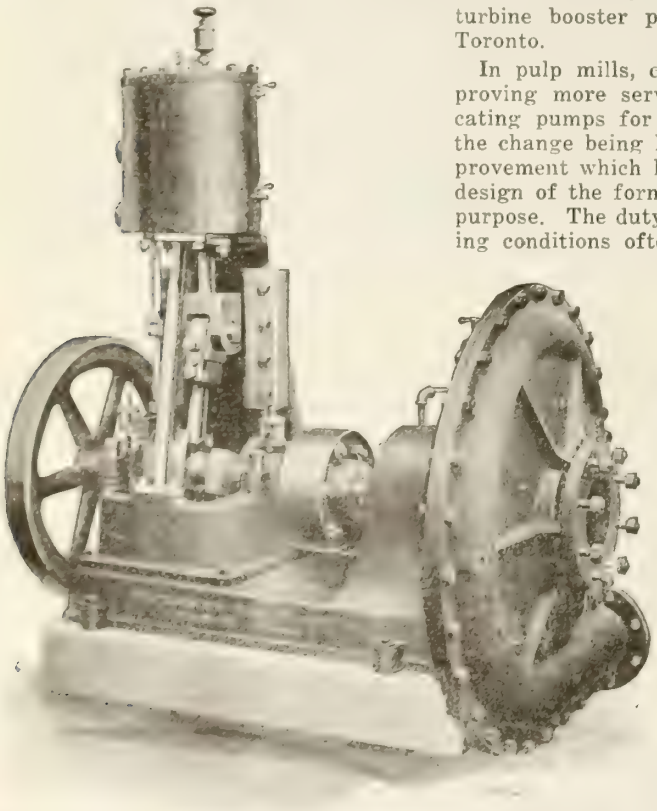
In pulp mills, centrifugal pumps are proving more serviceable than reciprocating pumps for handling pulp stock, the change being largely due to the improvement which has taken place in the design of the former for this particular purpose. The duty is severe and operating conditions often abnormal, thus requiring pumps with impellers of special design to meet the situation. In the design of all the different types of pumps, the company aims at efficiency in operation, accessibility of the various parts and standardization in manufacturing.

Centrifugal Pumps

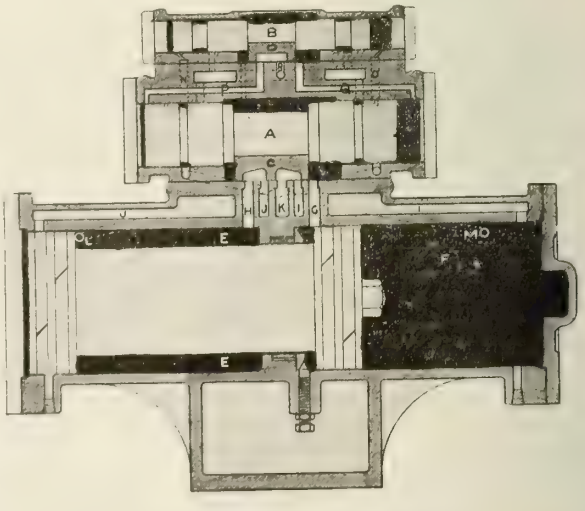
The Bawden Pump Co. makes standard single and double suction, single stage pumps, and also multistage centrifugal pumps. The single and double suction pumps are known as type "SS" and "S" respectively. The pumps are made for any kind of drive, the bearings being constructed accordingly. The general design is the same for all types except for certain details which will be described later. The pump casing is made in two castings split on a horizontal plane passing through the centre line of the shaft, so that the shaft and impeller can be removed, and the interior of the pump examined without breaking any pipe joints.

The bottom half of the casing containing the suction and discharge connections is bolted rigidly to the base. The top half or cover can easily be moved by means of eye bolts located on the top. All joint surfaces are machined to a smooth finish and therefore require only a very thin joint of prepared paper. All passages are free from sharp radii and are designed to give the fluid pumped a constant and even flow.

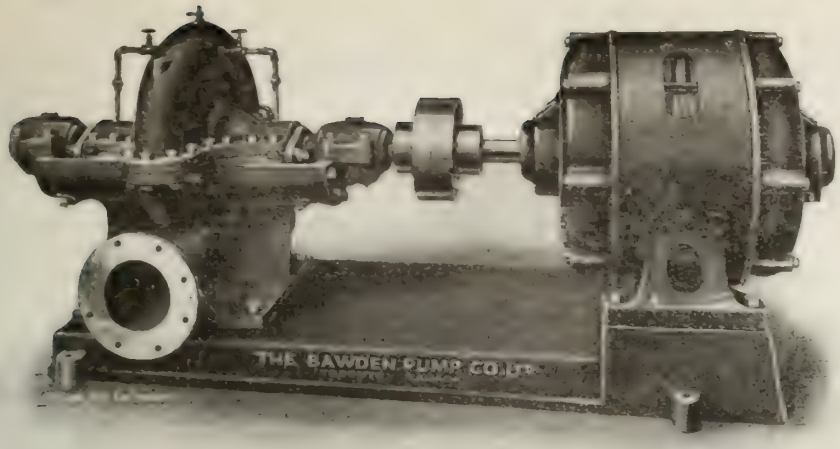
The design of the impeller is an important feature in these pumps. It is enclosed and is single or double suction according to the type of pump. It is balanced both for static and running balance. The impeller has two neck rings of different diameter, the one on the discharge side being larger than the one on the suction, therefore the effective area



STEAM DRIVEN CENTRIFUGAL PUMP FOR CONDENSERS, ETC.



VALVE ARRANGEMENT ON HORIZONTAL PUMPS.

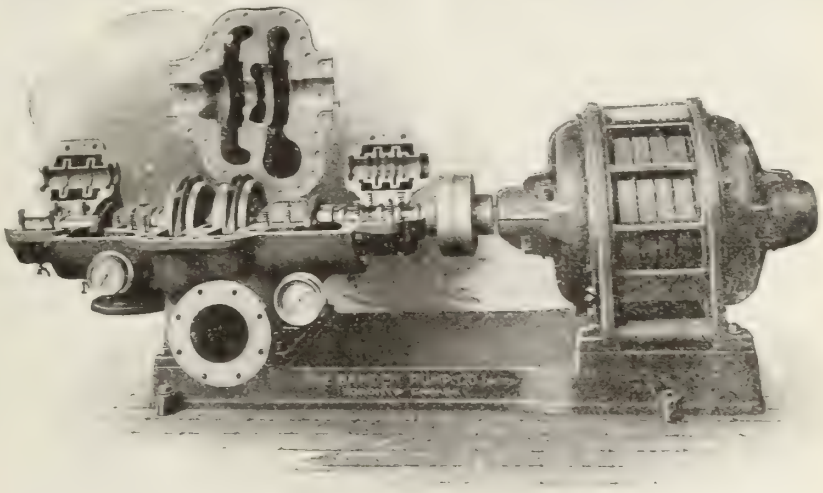


NO. 8. TYPE S DOUBLE SUCTION MOTOR-DRIVEN CENTRIFUGAL PUMP.

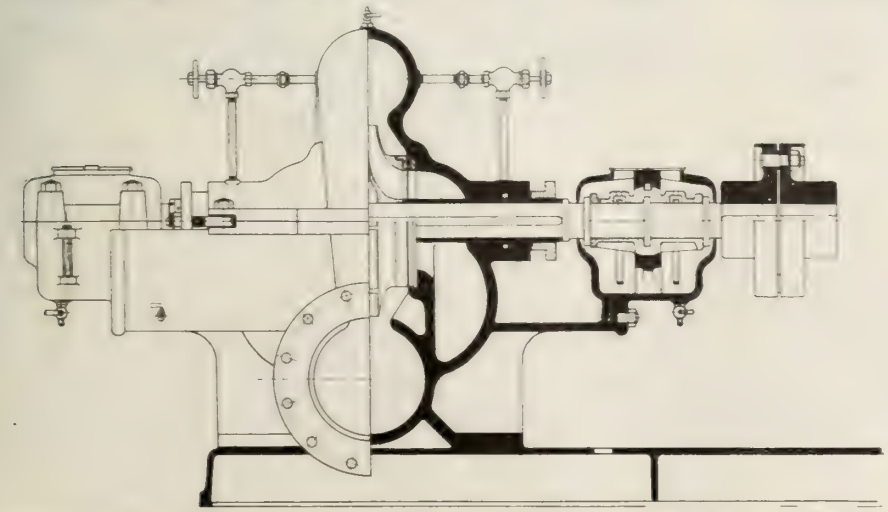
is larger on the suction than on the discharge side. The pressure being equal on both sides, combined with the relief and balance chambers, keeps the impeller and shaft in perfect hydraulic balance. The pumps have also a water seal. The blades of the impeller are carefully filed to templates so as to give the correct inlet and discharge angles therefore enabling the fluid pumped to enter and leave without shock. The neck rings are of the labyrinth type made of the same material as the impeller. One ring is secured to the impeller and the other to the bottom half of the pump casing. The design of the neck rings is such that liberal clearances are permissible without undue leakage.

The bearings, which are held on brackets, are entirely separate from the pump casing and stuffing boxes, water therefore cannot enter the oil chamber. The housings are split and are fitted with projections on the lower half so as to prevent the bushings from turning, at the same time allowing both halves of the bushings to be removed for inspection without disturbing the shaft and pump casings.

The bearing bushings are made of phos. bronze and not babbitt, giving less friction and less possibility of a breakdown through failure of the babbitt. The bearings which have ring oil lubrication are exceptionally long. To allow the impeller to float the shaft has ⅛-inch end motion. Both stuffing boxes are fitted with brass water seal rings connected through pipes to the pump casing or to the outside supply. The couplings on the end of shaft are of the flexible pin type. The coupling is made of cast iron, machined and polished, and fitted with steel pins covered with rubber sleeves, giving smooth running. This type of coupling is fitted to all double suction and multistage pumps, the single suction pumps having a solid pin coupling. The pump base is of substantial construction as will be observed in the illustrations.



TOP CASINGS REMOVED SHOWING ACCESSABILITY OF IMPELLER SHAFT AND BEARINGS. TYPE SS PUMP.



CROSS SECTION, TYPE S, DOUBLE SUCTION SPLIT CASING CENTRIFUGAL PUMP.

Special Service Pumps

The above description covers the standard types of pumps. The pumps for handling pulp stock differ in one or two details. For stock pumps the neck rings on the inside are removed and replaced by a wearing plate. The stock pumps are single suction, open impeller type. Pumps for handling acids are usually of the double suction type. They are made of special bronze, having acid resisting qualities. In these pumps all parts coming in contact with the acid are made of bronze, and the packings are made of asbestos. Pumps for handling chlorine liquor are made of cast iron throughout, the enclosed type of pump being used for this service.

Multistage and Turbine Pumps

Multistage centrifugal pumps have the same features as the single suction pumps. Each impeller is balanced individually, the method being the same for any number of impellers. The impellers have labyrinth neck rings on both sides. All neck rings and middle chamber bushings are made of "lumen" metal.

The turbine pumps are of the double-suction type and are suitable for special service where high heads are required with comparatively low speeds. The Bawden high lift turbine pumps are similar to the centrifugal pumps except that they are fitted with specially designed impellers and guide passages.

Circulating Pump

Another type of pumping unit which the Bawden Pump Co. has developed is a steam driven circulating pump for marine and stationary work, for condenser service, and also for contractors. The pump is designed for delivery of a large column of water at a low head. The pump is similar to the single suction type with hydraulically balanced impeller. The engine and pump form a complete unit, being mounted on a common base. It will be observed in the illustration that the engine is open type and the parts easily accessible. The engine is equipped with a balanced piston valve.

Balanced Valve Feature

The basic feature of the Bawden steam pump is the valve, which is of the balanced piston type. In this type of valve all tappets, levers, springs, rocker shafts, tubes or other gear have been dispensed with. A special feature of the Bawden piston valves is the arrangement for catching leakage steam due to wear and tear, for preventing them from getting into equilibrium at their driving ends. The steam piston is automatically cushioned at each end of the cylinder by a special design of the two main steam ports, therefore dispensing with all adjusting mechanism to compensate variations of speed, etc., and together with allocation of the drain cocks, makes the cushion effective under any emergency. The pump has no dead centres and makes a full length stroke at any piston speed and on any duty.

These pumps when of the vacuum type have long strokes and are well suited for producing high vacuums, and are equally effective when exhausting into any kind of condenser. The water ends in all types of pump are designed so as to offer facilities for inspection and repairs. These pumps have been found to be very suitable for boiler feeding purposes on account of their steady water pressures under varying loads and speeds. They can also be used as fire pumps as they can be operated at high piston speeds due to the absence of external valve motion.

Compound Pump

The Bawden compound pumps have the same valve gear as the simple pumps but are more economical in steam consumption. In the compound pump the high and low pressure pistons work in one cylinder, the steam ports are of the shortest length and so arranged that the high pressure steam in exhausting to the low pressure cylinder never leaves the main cylinder casting. There are no external passages, therefore radiation and condensation are reduced to a minimum. Only one steam chest is required and one valve to distribute the high and low pressure steam. The compound pump has also been proved to be a reliable and economical pump for boiler feeding purposes.

Special Types of Steam Pumps

The company also makes a duplex pump. The chief feature about this pump is that either side will work independently of the other, that is, if one side breaks down, the other side can be continued in operation. The Bawden oil pump is specially designed for pumping oil or other heavy liquids. The steam cylinders are the same design as in the standard pump, but they have a longer stretcher to more effectively prevent the liquid from being carried into the steam end. The pump pistons have split rings instead of packing. The valves are of the wing valve type and are usually brass double beat valves. The vertical boiler feed and sinking pumps are similar in design to the horizontal types but are built specially strong to withstand rough usage.

A special feature is cushioning of the piston which is positive under all conditions. They are self-starting even if submerged and will run fast or slow without any kind of adjustment. The special pump for fire service is of the compound type with the standard steam end. The water end is of the group valve type.

Standard Types of Pump

The standard boiler feed pumps for high pressure service are made in three main types, packed piston, packed piston pot valve and centre packed rain types. The water cylinders are constructed for pressures up to 100, 150 and 200 pounds respectively. The last two mentioned are made as either simple or compound pumps.

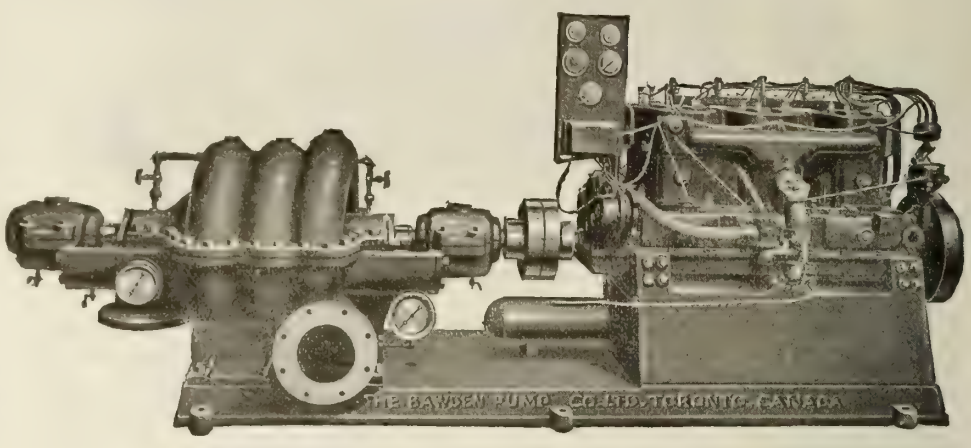
The general service pumps for medium pressures, 100 and 150 pounds, are made in two types, packed piston and packed piston pot valves. Two other general service pumps for high pressures 200 and 250 pounds are both centre packed ram type. The standard vacuum pump has a long stroke. The pump valves have large areas and are all water sealed.

Steam End Construction

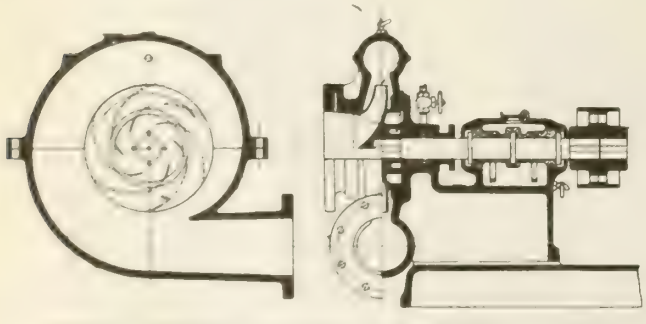
The principal features of the Bawden pumps as they affect the steam end have already been detailed. A few particulars regarding the general construction may now be in order. The construction of the steam end, except for sizes, is identical for all the standard types of pumps. The standard pumps are all centre outside packed, simplex horizontal, double acting, with steam thrown piston valves. In the compound pump the same balanced valve motion is used as on the simple steam pumps, enabling the high and low pressure pistons to work in one cylinder with one specially designed two-ported slide valve to distribute the high and low pressure steam.

The steam cylinders are designed to carry modern pressures. They are fitted with cast iron block pistons, self-adjusting cast iron rings and tobin bronze piston rods. The steam parts are of ample area and are designed to reduce steam clearances to a minimum. The pilot and main valves are of the back pressure "D" slide valve patterns, and are made of cast iron.

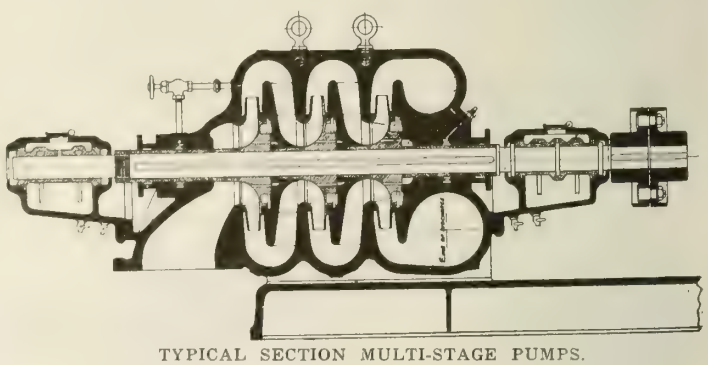
The valves are operated by pistons or plungers which are also ground into their respective steam chests, so that both valves, when so fitted and arranged to operate in conjunction with the main



8-INCH THREE-STAGE GASOLINE ENGINE DRIVEN EMERGENCY FIRE PUMP.

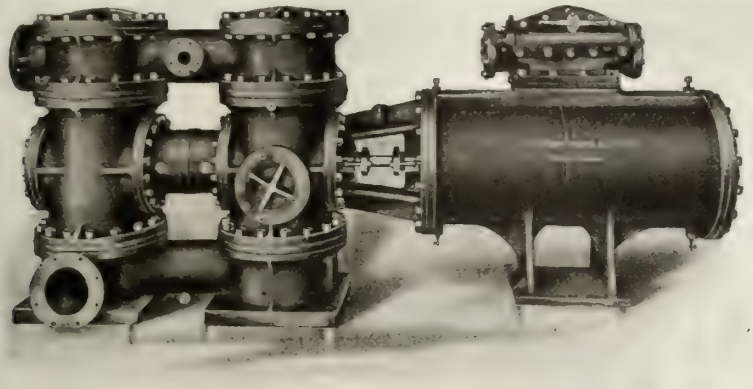


TYPICAL SECTION OF TYPE S.S. CENTRIFUGAL PUMPS.



TYPICAL SECTION MULTI-STAGE PUMPS.

piston ensures efficient cushioning of the latter under any duty, also instant operation of the valves therefore practically eliminating steam wire-drawing. The pumps are built up construction, the steam and water ends being separate units. They are held together rigidly by means of a stretcher which is machined to give perfect alignment. The stretcher is of flanged construction, heavy ribbed type, having the flanges containing the steam and water ends. The packing glands are easily accessible.



BAWDEN PATENTED GROUP VALVE INSIDE-PACKED COMPOUND FEED OR FIRE PUMP.

Water End Construction

The water ends of these pumps vary in design according to the type and service, etc. The water cylinders are of course designed to carry any pressure required. The cylinders have brass liners and are fitted with pistons packed with hydraulic packing. The rams are made of cast iron having brass sleeves pressed over the entire length and are securely cottered to the piston rod. The piston rod is made of tobin bronze machined to receive the ram and steam piston. In the packed piston type of pump the valves are made of iron or brass, the valve seats being brass with flat faces.

In this type of pump the valves are accessible through a hand hole at the side. In the pot valve pumps, the valves are made of specially selected rubber and are contained in separate valve boxes. Their seats are made of commercial bronze with flat faces. They are pressed into their respective valve pots and held in position by means of brass valve stoppers, screwed in through valve box covers and then locked in position with brass nut. All the rubber valves are supported with brass plates machined and recessed to receive the compression springs.

For the vacuum pump the steam end is the same design as the standard simple type of pump. The vacuum pump has a long stroke and the pump valves have large areas and are all water sealed. The pump body is lined with brass and the piston rod is tobin bronze. The suction valve deck is cast in one with the body. The discharge deck and pump cap are made in separate castings. The deck is accurately machined to receive the valve seats and is designed with a liberal factor of safety to withstand the duty designed for. The valves are made of specially selected rubber, the seats being made of good commercial bronze with flat faces, and pressed into their respective valve decks. The suction valves are pressed into position and held by means of the suction brass stoppers secured to the discharge seats, which are in turn held by the discharge valve stoppers in through the discharge cap and afterwards locked in position with brass lock nuts on the outside of pump proper. All rubber valves are supported with brass plates accurately machined and recessed to receive the compression rings. The water plunger is of the inside packed piston type and is made of cast iron. It contains two parts, the piston proper and the follower. The piston is accurately machined to give the proper tension to the water packing which is held in position by the follower.

The Bawden Pump Co. has recently developed a condensation pump and receiver. The outfit is in one unit and consists of a tank, pump, motor and automatic cut-out switch. A small centrifugal pump is bolted to a boss on one side of the tank and is connected to a one h.p. electric motor on the opposite by means of a phos. bronze shaft running through the tank. The shaft runs through suitable stuffing boxes and is connected to the motor by means of a flexible coupling.

By this arrangement the packing glands are only subjected to a head of approximately three feet of water. The discharge pipe is connected to the top of the pump and the return pipes from the heating system are connected to the side of the receiver near the top. As the tank fills, the copper float inside lifts and throws in the automatic switch, thus starting the motor and emptying the tank.

POWER PLANTS TO BE RATED BY U. S. FUEL ADMINISTRATION

The problem of how to obtain maximum economy in power generation throughout the country is being approached in a novel and commendable manner by the Fuel Administration of the United States. According to investigations conducted by that body, it is possible to effect a saving of ten to twenty per cent.—from 25,000,000 to 50,000,000 tons of coal per year—by helping owners of power plants to operate them correctly with their present equipment. This includes plants in the industries, in office buildings, hotels, apartment houses, etc.

Certain procedure will be followed in carrying out the programme as follows:

1. Personal inspection of every power plant in the country.

2. Classification and rating of every power plant, based upon the thoroughness with which owner of said plant conforms to recommendations.

3. Responsibility of rating the plants, which will fall upon an engineer in each district, the rating to be based upon reports of inspectors, who will not express opinions, but will collect definite information. The State Fuel Administrator, in his judgment, may entirely or partially shut off the consumption of coal to any needlessly wasteful plant in his territory.

4. Inspectors are to be furnished from one or more of the following sources: (a) Inspectors of the steam-boiler insurance companies; (b) State factory inspectors; (c) engineering students from technical colleges; (d) volunteers.

The ratings will be based upon recorded answers to questions, each of which will be given a value depending upon its relative importance to the other questions. Depending upon the efficiency of methods in use in any plant, it may be rated in class 1, 2, 3 or 4.

Advance Notice of Inspection

In advance of the first inspection a questionnaire will be sent to every power plant in each district, with notice to the owner that within 60 or 90 days his plant will be inspected personally and the questionnaire will be checked up by the inspector upon his visit. This action, it is believed, will tend to prepare the minds of plant owners for what will follow and will operate to produce a desire to improve plants, if necessary, so that they may be rated in a high class by the time the inspector calls.

The Fuel Administration has prepared a 50-minute film of moving pictures showing good and bad operation in the steam-boiler plant, methods of testing boilers, fuels, etc. These pictures will be available for each State in connection with its educational propaganda.

The administration is also preparing a series of official bulletins on engineering phases of steam and fuel economies. Some of these are now ready for printing. They will include: Boiler and furnace testing; flue gas analysis; saving steam in heating systems; boiler-room accounting systems; saving steam and fuel in industrial plants; burning fine sizes of anthracite; boiler water treatment; oil burning and stoker operation.

In addition to this service, a list of competent engineers has been prepared in Washington for each State and is available for use of each local administration. As the work develops, still further constructive assistance is contemplated for helping owners to bring their plants up to a high plane of economic operation.

Electricity and Hydraulics

PRINCIPLES AND OPERATION OF MODERN ELECTRICAL EQUIPMENT—IV.

By A. M. Pere.

THE operation of all dynamo electric machinery is based on the production of an electric current in a conductor by the action of magnetism.

Magnetic flux is a term used to express that property of a magnet whereby its action is made known in its effects on magnetic objects, such as iron or steel, and by its property of generating an electric current in a conductor under suitable conditions.

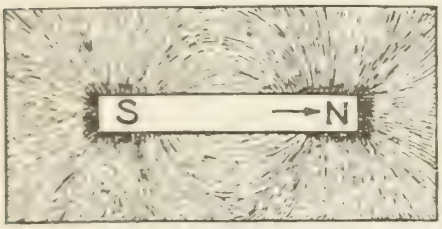


FIG. 1 MAGNETIC FIELD AROUND BAR MAGNET.

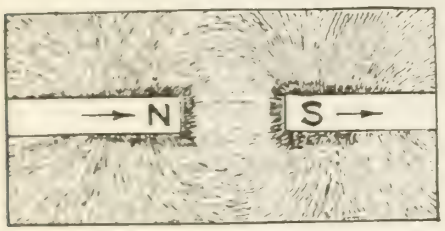

FIG. 2—MAGNETIC FIELD AROUND NORTH AND SOUTH POLES.

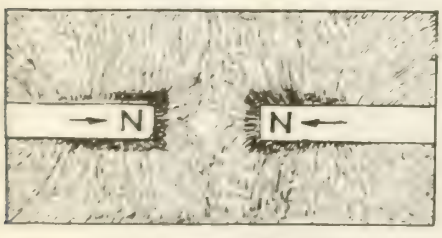

FIG. 3 MAGNETIC FIELD AROUND TWO NORTH POLES.

The act of magnetization not only alters the steel, but alters the space around the steel, causing it to assume a state of stress or strain.

If a magnet be plunged into clean iron filings they will be found to adhere in tufts, clinging chiefly to the ends or polar regions of the magnet. If such a tuft be examined it will be found that each hair or strand of the tuft consists of a lot of filings which have arranged themselves as a chain. This property of a magnet may be shown very clearly by covering the magnet with a sheet of cardboard upon which iron filings have been sprinkled; and if the cardboard be gently tapped the filings will assume the form of a series of curves, arranging themselves in more or less continuous lines from one pole to the other, as is shown in Fig. 1.

These curves, while interesting in themselves, render visible to the eye the paths of forces which would be otherwise invisible, and the mechanical forces which magnets exert upon each other and magnetic objects in their neighborhood can be very clearly depicted by this means. Wherever we find these lines of force crossing any part of space there is a mechanical tension or pull, just as if the lines were stretched threads of rubber or some other elastic substance. This state of strain really exists in the neighborhood of the poles of the magnet, and is only made visible by the behavior of magnetic objects brought into its field of action.

If two bar magnets be brought near each other in such a manner that a north pole and a south pole are adjacent to each other and a sheet of cardboard be placed on top, sprinkled with iron filings and lightly tapped, the curves formed by the filings will show that the lines of force proceed from one pole to the other, spreading out on the way, as shown in Fig. 2. But if two north poles are brought together the filings will arrange themselves as if the two magnets and the lines of force repelled each other, much as is shown in Fig. 3. Such is the case, and under all conditions like poles repel and unlike poles attract. This is explained on the assumption that the magnetic flux has sense or direction. It is understood that the magnetic flux flows out of the north pole and in at the south pole of any magnet.

The Earth's Magnetism

The earth itself is a magnet, and to this fact we owe that useful instrument, the compass, for if a magnet be freely suspended it will be found to turn and point in a direction almost due north and south.

The north magnetic pole of the earth is not of the same polarity as that of the north pole of a magnet, for we have just shown that like poles repel. The north and south poles of a magnet, strictly speaking, are the NORTH SEEKING and SOUTH SEEKING poles respectively. Fig. 4 shows an elementary diagram illustrating this. The north pole of the magnet is shown as having the flux coming out of it, proceeding to the north pole of the earth, emerging at the south pole and entering the south pole of the magnet. This fact once established, no difficulty is ever encountered in remembering the relation of a magnet's poles to the earth's magnetism.

FIG. 4—RELATION OF THE EARTH'S MAGNETISM TO THAT OF THE BAR MAGNET.

The true magnetic poles of the earth do not correspond exactly in location to the geographical poles, but are a considerable distance away and shift slightly from year to year. The magnetic north pole of the earth is more than 1,000 miles away from the actual pole, being in lat. 75° 5′ N. and long. 96° 46′ W.

Magnetism and the Electric Circuit

Magnetism and electricity are very intimately related; so much so, in fact, that one can hardly be studied without the other.

When an electric current flows along a wire a magnetic field is set up in a circular direction around the wire. Fig. 5 represents a conductor in which the current is flowing from the observer to the paper. This direction is indicated by the cross in the centre of the wire. This cross represents the tail feathers of an arrow travelling in the direction in which the current flows. The opposite direction is represented by a dot shown in Fig. 6, which indicates the tip or point of the arrow. This convention is often made use of, and is very convenient. In Fig. 5 the direction of magnetic flux around the wire is in a clockwise direction. If the current travels in the op-

posite direction the flux is also reversed, as in Fig. 6, and a compass needle, as shown, points the opposite way.

Many analogies are used as an aid in remembering this relation between the directions of magnetic flux and current, and perhaps the most useful of them is that of the right-hand nut and screw. If a right-hand screw be held in the hand

FIG. 5 — MAGNETIC FIELD AROUND A WIRE CARRYING CURRENT IN A DIRECTION FROM THE OBSERVER.

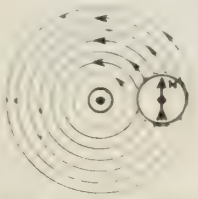

FIG. 6 MAGNETIC FIELD AROUND A WIRE CARRYING CURRENT IN A DIRECTION TOWARDS THE OBSERVER.

and the nut spun around on it, the direction of travel of the nut along the screw represents the direction of flow of current, while the direction in which the nut is rotated corresponds to the direction in which the magnetic flux travels.

The Solenoid and Electro-Magnet

If a coil of wire be wound, as in Fig. 7, and a current is sent through it, as shown by the arrows at the ends of the wires, the magnetic field created around the wire will form magnetic poles at the ends of the coil similar to those of the common bar magnet. A little consideration will show that the magnetic flux around the wire will travel in the directions indicated by the arrows, and that the effect of the coils will be considerably stronger than that of a single straight wire.

A useful rule for connecting the direction of the current and the direction of the magnetic flux in a solenoid or elec-

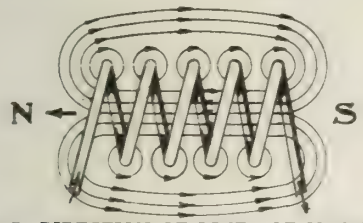

FIG. 7—DIRECTION OF LINES OF MAGNETIC FORCE THROUGH A SOLENOID.

tro-magnet is as follows: Grasp the solenoid or coil with the RIGHT hand in such a manner that the fingers point in the direction in which the current flows around the coil and place the thumb on the top of the coil as shown in Fig. 8. The thumb will then point in the direction in which the magnetic flux flows, i.e., towards the north pole of the solenoid or electro-magnet.

If a bar of iron is placed in the centre of the coil of wire shown in Fig. 7 the magnetic effect of the current will be found to be very much increased. Iron has the peculiar property of being a much better conductor for magnetic flux than other materials and thus increases the strength of the magnetic field in much the same manner that a wire of copper will pass a greater quantity of electricity than will an iron one of the same size and length, under the same voltage. This quality is called the permeability and is shared to a slight degree by cobalt and nickel. Practically all other materials are much poorer conductors of the magnetic flux and all are about equal in this respect. The permeability is measured by taking that of air as the standard and making it equal to one. Wrought iron and cast (machinery) steel have about the same permeability, which may easily reach a value of 1,200 or 1,500. This means that in a closed magnetic circuit such as would be formed by winding a coil of wire around a ring of soft iron, 1,200 to 1,500 times as much flux would pass through the iron as would pass through an air current of the same dimensions for an equal current strength.

Flux Density and Saturation

In many problems it is important to be able to express the amount of flux as a numerical quantity and a unit has been chosen for this purpose called the Maxwell. This name is somewhat out of use at present and in place of saying so many Maxwells it is more usual to say, so many lines of force. The flux density or the strength of the magnetic field is measured in lines per square centimetre. This quantity is important because iron has a peculiar variation in its permeability such that when magnetized to a high flux density the permeability or capability for further magnetization greatly decreases. Under such conditions the magnetic material is said to be getting saturated and with very high flux density is said to be saturated. Saturation is a rather indefinite term. With good wrought iron or steel it would be reached at something like 20,000 or

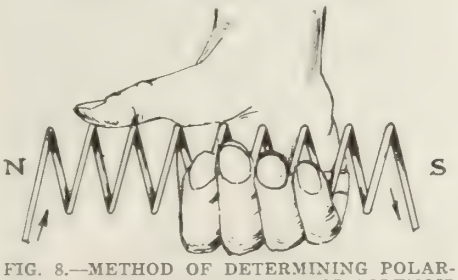

FIG. 8.—METHOD OF DETERMINING POLARITY OF AN ELECTRIC-MAGNET OR SOLENOID

more lines per sq. cm. while in cast iron it would be at 8,000.

Ampere Turns and Magnetic Flux

The magnetic flux created by a current increases as the current increases, decreases as the current decreases, and is reversed in direction when the current is reversed.

The amount of flux created in a magnet varies as the number of turns in the winding, and as the number of amperes passing through it. This is to be expected for it may reasonably be supposed that two turns would cause twice the amount one would. This is correct when low densities are considered but when the iron approaches saturation naturally it no longer holds good. The product of the number of amperes and the number of turns is called ampere-turns and equal numbers of ampere-turns create equal magnetic flux in similar circuits. This is true no matter whether one ampere and ten turns or ten amperes and one turn be considered.

Answers to Last Month's Problems

1. The current produced through a resistance of 5 ohms by an e.m.f. of 10 volts will be $10 \div 5 = 2$ amperes.

2. An e.m.f. of 15 volts will produce a current of 3 amperes through a resistance of $15 \div 3 = 5$ ohms.

3. To produce a current of 4 amperes through a resistance of 4 ohms will require an e.m.f. of $4 \times 4 = 16$ volts.

4. The current will be $500 \div 20 = 25$ amperes.

5. The dynamo must generate a current of $20 \times .2 = 4$ volts.

6. The smallest e.m.f. that will ring the bell will be $400 \times .03 = 12$ volts.

7. The resistance necessary to limit the current to a value of 5 amperes will be $500 \div 5 = 100$ ohms.

8. The total resistance of the circuit neglecting the line resistance will be $150 \div 25 = 6$ ohms. The resistance of the dynamo is one ohm. Deducting this leaves a value of 5 ohms for the resistance in question.

This Month's Problems

1. In what direction does the magnetic flux flow out of a magnet?

2. Does the north magnetic pole of the earth correspond to the north pole of a bar magnet, as regards the direction of flux travel?

3. Draw a diagram showing the relation between the magnet and the earth's magnetism and then compare it with Fig. 4.

4. In what direction does the magnetism flow around a conductor carrying current; does any other analogy besides that given in the course occur to you in this particular?

5. What is the effect of coiling a conductor carrying current into a helix or coil?

6. What method may be used for determining the polarity of a solenoid?

7. What is meant by the term ampere-turns?

8. If 25 amperes flow through a coil having 100 turns, how many ampere-turns result?

READER'S QUERY

The factory with which I am connected obtains its power from an outside source. Three single-phase transformers of 250 kv.a. capacity each serve to transform the incoming line voltage of 13,200 down to 550 volts, at which voltage it is distributed throughout the shop for the operation of the various three-phase motors.

We are experiencing considerable trouble with the secondary cables which run from the transformers to the switchboard. These secondary connections consist of three single-core lead covered 750 m.c.m. cables, each of which runs through a separate iron conduit to the board. These pipes are hot to the touch and great inconvenience has been

caused by the end-bell compound running out of the endbells on these cables at the switchboard. The transformers are hardly ever run at rated capacity and the power factor is about 85. Are the cables too small for the load carried or is there some other trouble? H. A. B.

Answer. — The trouble experienced above is one which occurs quite frequently if the design in any respect is at fault. The primary cause for the flowing of the end-bell compound is of course the heating in the cables, and the reason for the location of the trouble at the switchboard will in all probability be found in the difference in elevation between the two ends of the cable. While the material with which the cable is impregnated is very viscous and while the end-bell compound at normal temperatures is nearly in a solid state, yet given sufficient time and a sufficient temperature rise both will flow like any liquid though at a slower rate. End-bells are manufactured which are absolutely tight and are able to resist the head or pressure caused by the compound under similar conditions to the above.

The rise in temperature is not alone due to the resistance of the conductors but in this case is due to hysteresis in the iron conduit or pipe surrounding the single conductors.

When a current of electricity flows through a conductor a magnetic field is set up in the space surrounding the wire and when a single conductor is carried through an iron pipe the pipe is very strongly magnetized, given sufficient current. When the current reverses the magnetic flux also reverses. This reversal of magnetic flux requires a certain amount of energy for its accomplishment and this energy is dissipated in the form of heat. When the two sides of a single-phase circuit or the three leads of a three-phase circuit pass through the same pipe or conduit the resultant magnetic field due to the currents flowing is zero for the outgoing and return currents are equal in value and the direction of magnetic flux is opposite in each.

POLARITY INDICATOR

The query in last month's issue regarding the composition of the liquid used in a polarity indicator has reminded me of another solution which has been used with good results. If a few crystals of iodide of potassium are dissolved in water and then a little starch paste is added a very sensitive electrolyte is obtained which turns to a dark blue color at the anode when a very weak current is passed through it.

The decomposition of the iodide of potassium liberates iodine at the anode or positive pole which, acting on the starch in the solution, turns it a dark blue color at the anode.

Montreal. FRANK WILLIAMS.

PLATINUM is first recorded in Russia in the year 1821, when it was distinguished in the working of alluvial gold in the Ural mountains. Its value was not appreciated then, hence the discovery attracted little attention.

Torsion Meter for Power Transmitted by Propeller Shafts

The advent of the turbine introduced new problems in the measurement of power developed by marine engines. The conditions under which such apparatus is used on board ship demand simplicity of construction and reliability of operation. The apparatus described in the following article has proven satisfactory in actual service and is the result of efforts to combine extreme accuracy and lightness with the aforementioned features.

EXTREME accuracy, simplicity of construction, and lightness for unit length of shaft combine to insure the success of the Gary-Cummings torsion meter. This meter is the result of long experience with various power measuring instruments on board ship and the makers have been able, through their own efforts as well as through the experience of users with whom they have kept in close touch, to bring this instrument to a high state of prefection.

The personal equation is entirely eliminated from the readings on this type of torsion meter. These are recorded mechanically and form a permanent record for future reference if desired. All parts of the meter which are subjected to centrifugal action are made as light as possible and balanced perfectly. The instrument is largely housed within the shaft entirely out of the way. When space is limited, as on torpedo-boat destroyers, this feature is of great importance. All parts which might possibly get out of order are attached to the outside of the shaft flange where they can be readily inspected and removed or replaced in a very few minutes. The instrument contains no gears whatever. Another feature that contributes largely to its accuracy is the fact that it measures the torsion in one complete section of a shaft, making necessary but one multiplying device. There is but one part to wear and this is easily taken up, giving considerable advantage over those meters which attempt to measure the angular twist in a short section and require numerous multiplying devices all of which are a possible source of error in the reading.

Construction

The instrument is primarily a rigid steel tube extending for one complete shaft section and fastened rigidly at one end but free to move at the other. The fixed end of this tube is firmly attached to an arm which rests in a radial slot in the flange of the shaft where it is securely fastened. Along the steel tube at intervals are spider collars which fit loosely but are held from moving along the tube by long cotter pins placed through the tube on each side of the collar. These spiders eliminate all possibility of any whipping action. The free end of the steel tube is supported and centered in a ball bearing so that it is free to rotate with respect to the shaft. It is therefore free to transmit any angular displacement between the tube and the shaft to an arm which is secured across the end and extends radially through another slot in the shaft flange in which it is free to move angularly. In other words, any angular displacement between the two flanges on the shaft can be noted by the movement of this arm with respect to the flange. An umbrella, equipped with two recording points, is fastened securely to the outside of the shaft flange at the free end of the tube in such a way that it is capable of rotating in a plane at right angles to the shaft. Any movement between the arm and the flange is transmitted through a sliding ball joint to the umbrella, causing it to turn an amount which is directly proportional to the twist in the shaft. The two points on the periphery of the umbrella record on a specially prepared card placed in a holder at the side of the shaft as it revolves and are adjusted so as to cause a small negative reading when no power is being transmitted. When the shaft is transmitting power the distance between the two marks recorded on the card minus the zero reading is directly proportional to the twist in the shaft. From this measurement the actual torque transmitted by the shaft can be readily obtained from the calibration data. Using this and the revolutions per minute of the shaft the horsepower transmitted is easily calculated. If the record of the shaft revolutions is noted on the same card with the torsion meter reading, a permanent record is obtained which can be filed for future reference.

Torsion Member

In constructing this meter unusual care is exercised to secure an absolutely rigid fastening at the fixed end of the meter tube. The supporting spider is turned to fit the inside of the shaft with a tight fit. On the spider is a collar into which the steel tube fits and to which it is riveted solidly. The radial arm is secured to the spider head by machine screws prick-punched to prevent unscrewing. The arm itself fits tightly into the slot cut in the shaft flange and is secured by bolts through the flange. This construction eliminates the possibility of any play at this end of the tube.

The free end of the tube is riveted to a suitable collar which rests in a ball-

bearing within the spider which supports and centers this end of the tube. The spider is carefully made to fit within the shaft and is then secured there by tapered plugs in each spider leg which expand the four ears hard against the walls of the shaft. Further stability is added to the spider by two webs connecting opposite adjacent ears. The tube is thus supported and centered at this end but is free to rotate, or to move along the shaft as it expands or contracts. The position of the meter tube is therefore controlled entirely from its fixed end. The relative position of the two flanges is what the meter must measure and what is transmitted to the recording umbrella.

To understand the instrument it must be borne in mind that the tube is secured to one flange of the shaft only. It is free to rotate in the other flange; therefore the meter tube itself cannot possibly be subjected to any twisting action, but it is the shaft that twists about the meter tube, and it is this twist or difference in displacement between the shaft and the tube that is measured.

Recording Device

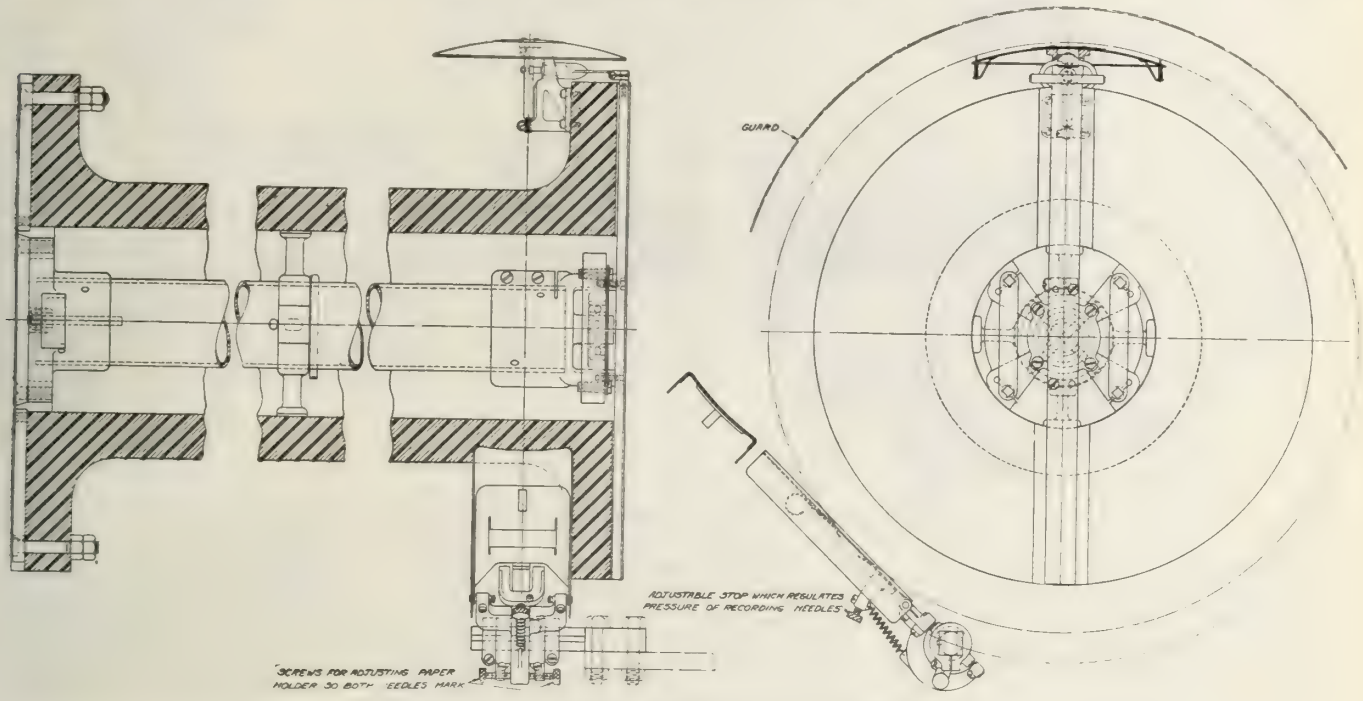
Probably the most interesting part of this torsion meter is the method of recording the twist of the shaft. A V-shaped or butterfly arm extends from the radial piece to the sliding ball joint which moves the umbrella. This butterfly piece is pivoted, as shown in the sketch, to the radial arm in order to provide for the very slight but positive movement of this arm in a plane vertical to the shaft axis. The pivoting joint can be easily adjusted for wear or for an approximate zero reading by the conical screws at each end. At the sliding ball joint provision also is made for taking up any possible wear. The ball is fastened to the supporting axis of the umbrella so that any angular movement of the radial arm attached to the free end of the meter tube causes a proportionate rotation of the umbrella. The recording points are set on opposite sides at the outer edge of the umbrella. When the shaft rotates these recording points move in a plane perpendicular to the shaft. As the shaft is twisted, the plane of rotation of one recording point moves aft and the other forward to correspond with the amount of twist in the shaft. The needles record on a card the exact distance between these planes. The prepared card is held in a holder supported from the hull or bearing foundation. The plane of the card must form practically a tangent with the circle described by the points of the needles when recording. When not taking readings a spring keeps the card away from the recording needles. All that is necessary to take a reading is to push the card-holder forward against an adjustable stop and the needles will record as the shaft rotates.

The card-holder itself has to be carefully constructed to obtain the best results. The opening for the needle record is only 3¼ inches wide by 2½ inches high, and in order that the needle readings may be properly centered on the card the holder contains a screw adjustment for moving the opening in the holder forward or aft parallel to the shaft axis a short distance. Provision is also made for adjusting the recording card so that both needles will mark properly. Ootherwise, only one needle would record. With these two adjustments the recording holder can take care of all variations due to temperature and the like.

Calibration

In order to obtain the best results, the shaft should be calibrated after the meter is installed in the section in which it is to be used aboard ship. The torsion meter is installed in the shaft exactly as aboard ship except for the card-holder. The shaft is placed on two suitable supports and the end containing the fixed end of the meter securely fastened to a heavy fixed girder. The opposite end of the shaft is supported by a bearing which allows it to turn in an angular direction with as little friction as possible. To this free end of the shaft another girder it attached for applying the test loads. Whatever apparatus is used it is necessary that the turning forces shall be balanced so that there will be no eccentric twist in the shaft. The usual method consists of applying known weights at one end of the beam and a turn-buckle or jack with a weighing scale at the other end. Suitable corrections are made for the weight pans and the turn-buckle with its attachments. The weights in the pan at one end act downward while the turnbuckle must act with equal force in an upward direction at the other end of the girder. The points at which the turn-buckle and the scale pan act upon the girder should be knife edges carefully measured from and on the same line with the axis of the shaft. For convenience these distances are usually made equal.

Of course the recording umbrella does not rotate around the shaft axis during this calibration test as it does when installed in the ship. Extra provision must, therefore, be made for properly recording the angular twist obtained during this test. The record card is placed in a small holder carried by an arm that rests on a special plate on the shaft itself. This supporting plate is fitted to the circumference of the shaft and when moved around the shaft causes the record card to describe a circle whose center is at the center line of the shaft.



GUARD
ADJUSTABLE STOP WHICH REGULATES PRESSURE OF RECORDING NEEDLES
SCREWS FOR ADJUSTING PAPER HOLDER SO BOTH NEEDLES MARK

DETAILS OF TORSION METER AND CARD HOLDER.

As the card passes the recording needle two parallel lines are traced. The distance between these lines is a measure of the twist or torque applied to the shaft.

Applying Load

In conducting a calibration test the needles should be adjusted so that the zero reading will be from ten to fifteen-hundredths of an inch, and a card taken. A known moment is applied to the shaft which is then rapped sharply with a lead hammer to remove any "set" that may have been caused by binding in its bearing, and a record taken from the recording points on the umbrella. Weights are then added in increments and the turn-buckle adjusted each time for the same upward thrust. The shaft should be thoroughly rapped each time with lead hammers before readings are taken. These operations are continued until the desired load has been reached. To check this, similar records are taken as the load is removed step by step. From these results, with proper corrections for zero readings of the instrument, the calibration curve for the meter is easily plotted. Torsion meter readings are plotted as abscissae and the torque, which is the equivalent load at one-foot radius, as ordinates. If the test has been properly conducted the resulting curve will be a straight line, indicating that the angular twist in the shaft is directly proportional to the load applied; this will, of course, be the case up to the elastic limit of the shaft. If the curve is a straight line it proves that the calibration is correct unless there was an error, such as friction, common to all points.

From the calibration readings the torque per one inch of meter reading is calculated. This will be found practically the same for all the loads applied to the shaft. Theroretically it should be exactly the same. The average of these gives a figure on which to base the horsepower constant for that meter in that particular shaft. To facilitate the ready calculation of the power transmitted, however, the constant used for each shaft contains the additional constants which enter into the calculation of the horsepower.

Calculations

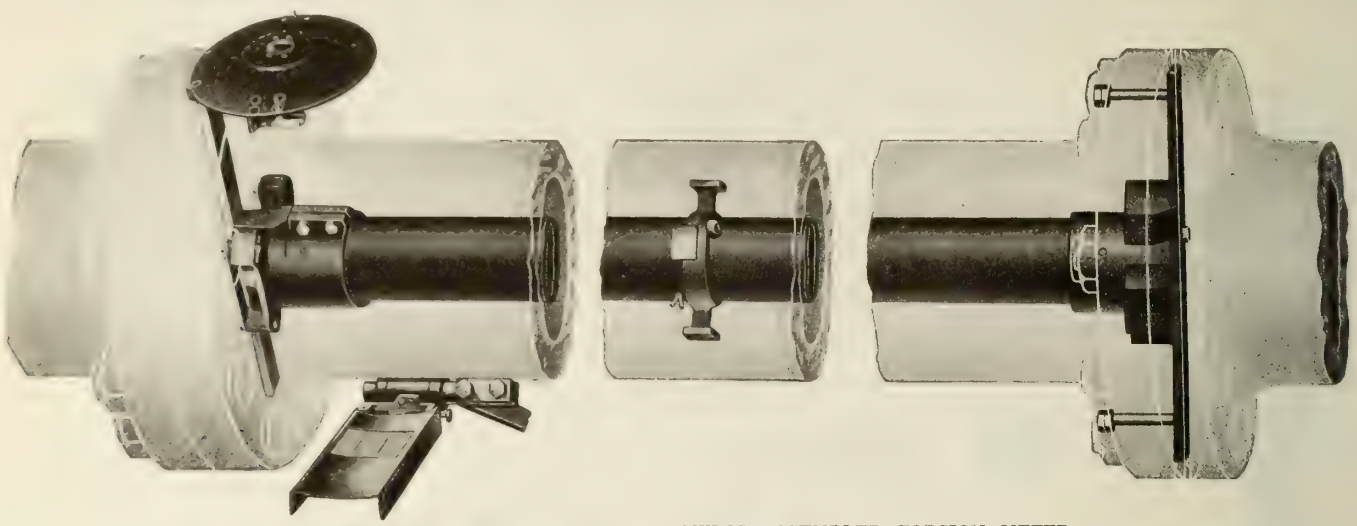
Algebraically, the calculations are as follows:

$$S.\ H.\ P. = K \times T \times RPM$$

R = radius on which load is applied in feet.

W = weight of load in pounds.

RPM = revolutions per minute.



PHANTOM VIEW OF SHAFT SHOWING ASSEMBLED TORSION METER.

M = torque or moment in foot pounds.

Q = foot pounds for 1 inch torsion meter reading.

T = torsion meter reading in inches.

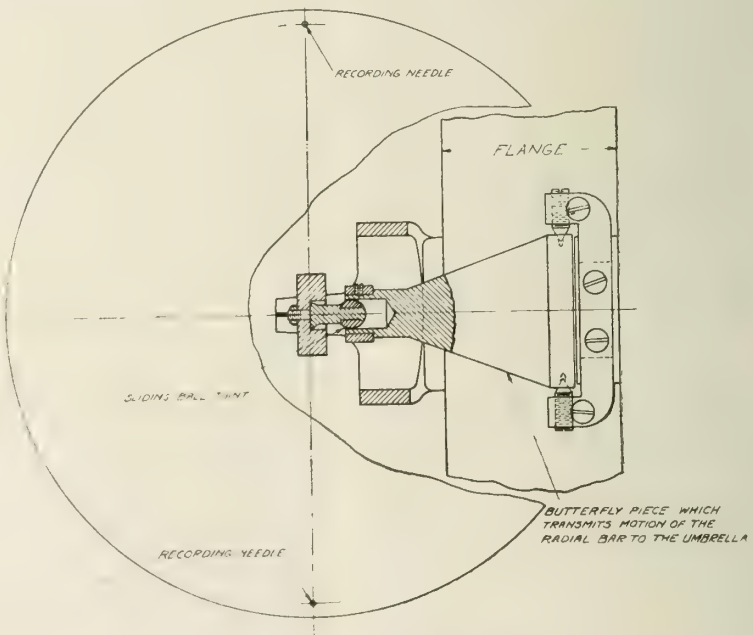
K = torsion meter constant.

From this equation the horsepower transmitted through each shaft in the ship is calculated, and when noted on the sheet containing the torsion meter reading becomes a part of a permanent record of the test.

In the use of this meter aboard ship it is essential that the needles record a small negative reading when the shaft is transmitting no power—that is, when the propellers are dragging, but still turning over. This zero reading is obtained by properly adjusting the set screws joining the butterfly piece with the radial arm when the meter is is installed. If the meter was set for no zero reading, that is, both points marking the same line on the card, it would not be possible to tell whether both needles were recording or not. With the small negative reading, however, it is easy to note that both needles are recording properly.

Setting Recording Needles

A gauge in the spare-part box fits the flange with a tongue projecting out to set the height of the recording needles.

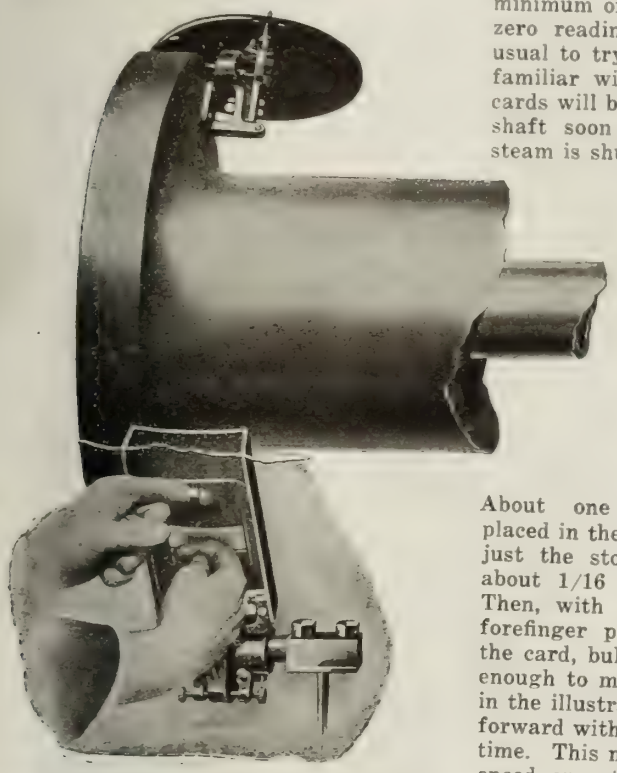


RECORDING NEEDLE
FLANGE
SLIDING BALL JOINT
BUTTERFLY PIECE WHICH TRANSMITS MOTION OF THE RADIAL BAR TO THE UMBRELLA
RECORDING NEEDLE

SECTIONAL VIEW OF BUTTERFLY PIECE AND SLIDING BALL JOINT

These should be set with a watch key (No. 4 key in spare-part box) so that they just touch the gauge as it is moved around the flange. Then both recording

points are at the same distance from the centre of the shaft and will record when the card is brought in contact. By means of the centring screws on the block attached to the top of the bar the needles are set so that one is about ⅛ inch farther from the flange than the other. The mark on the gauge should be equidistant between the planes of the



THE MOST CONVENIENT WAY OF TAKING CARDS.

needles. This is the approximate zero reading.

The needles are set so tht their planes of rotation do not cross when the shaft twists in ahead direction, otherwise the zero reading would have to be added to the reading taken when under way instead of being subtracted as it should be.

Operation

In running a test the recording apparatus is attached to the shaft, care being taken to scrape the rust and dirt from the flange. The butterfly piece should be adjusted by the centring screws, so that it is freely movable without lost motion.

The Card-Holder

The card-holder is attached by two bolts to its support, which should be built out from the frame of the ship. By loosening the binding screws on the collars over the round bar the holder may be moved forward or aft, so that the centre of the opening is in the plane of the axis of the umbrella as it revolves with the shaft. Otherwise, when the shaft twists one needle would mark on the card and the other would be out of range.

Getting Zero Reading

After tightening all screws the torsion meter is ready for dragging the shaft. This should be done by getting some way on the ship, about one-third speed, then shutting off the steam to the turbine, including all auxiliary exhaust, and permitting the shafts to revolve partly by way of the ship and partly by its own inertia and that of the rotor. Cards should be taken at frequent intervals while the shaft gradually slows down and the minimum of these readings taken as the zero reading. Before dragging it is usual to try taking cards in order to be familiar with the operation so that no cards will be lost during the drag, as the shaft soon stops revolving after the steam is shut off. One man, experienced at taking cards, should be at each torsion meter while the shafts are dragging.

Taking Readings

Since the stop was set so that needles would not touch the card when the ship geats under way, the first thing to do is to adjust this stop so that the needles just make a mark without tearing the card. About one dozen cards should be placed in the holder. Some prefer to adjust the stop so that the needles are about 1/16 inch away from the card. Then, with a slight pressure with the forefinger placed horizontally back of the card, bulge it outward slightly, just enough to make needles work, as shown in the illustration. The holder is sprung forward with the other hand at the same time. This method is used by all experienced operators, because it lessens the danger of the needles striking metal and does not require such a fine adjustment of the stop screw. It is attended, however, with some danger of getting the fingers cut slightly by the revolving needles, so should not be attempted by careless operators. Should one needle mark before the other, the card should not be pushed farther in, but the side thumb screws should be adjusted, backing off one and tightening up the other. (Be sure holder is held tightly between these two adjusting screws before taking another record.) Keep trying this until both needles mark.

To calculate the horsepower a card is taken at the same time the revolutions per minute are being determined. Very often the torsion meter operator will take counter readings of each shaft on the minute, then go aft and take torsion meter cards, then counter readings again, say five minutes later. Each card should be marked with the shaft from which it was taken and also with the date and time. The revolutions per minute of each shaft are worked out for five minutes and noted on the cards also. The linear distance in inches between the two parallel marks on the cards minus the zero reading (in rare cases this is plus because planes of needles cross as shaft twistsis) is the corrected tersion meter reading. A convenient scale is furnished each ship for measuring cards. Multiply the corrected reading (in inches and fractions thereof) by the torsion meter constant and this result by the revolutions per minute of the shaft final result will be the horsepower being transmitted through the shaft. The torsion meter constant is worked out from the shop calibration of the shaft, as already described.

A NEW WOOD, THE LIGHTEST KNOWN

By D. Street.

A NEW wood, apparently little known and called balsa wood, is exceedingly light and promises to have an extended field of usefulness in connection with cold storage structures when heat insulation is important. It is a tropical wood, growing principally in the States of South and Central America.

The wood is remarkable—first, as to its lightness; second, as to its microscopical structure; third, for its absence of woody fibre; fourth, for its elasticity; and fifth, for its heat-insulating qualities. So far as investigation has disclosed, it is the lightest commercial wood known. It has also considerable structural strength, which makes it suitable for many cases. In general appearance balsa wood resembles bass wood.

Until recently Missouri cork wood, weighing 18 lb. per cubic foot, was believed to be the lightest, but recent investigations indicate that balsa wood is much lighter, having a net weight of 7.3 lbs. per cubic foot. The ordinary commercial balsa wood is seldom perfectly dry, and because of the moisture content its weight has been found to be between 8 lbs. and 13 lbs. per cubic foot.

The extreme lightness of this wood suggests its application as a buoyancy material in life-preservers and life-boats. When, however, it was attempted to apply the wood practically it was found to be of little value, because it absorbed water in great quantities, and also because it soon rotted, and also warped and checked when worked. After testing nearly every method that had been suggested, Colonel Marr's method of treating woods, which had been recently patented, was finally successful. In this method the wood is treated in a bath, of which the principal ingredient is paraffin, by a process which coats the interior cells without clogging up the porous system. The paraffin remains as a coating or varnish over the interior cell walls, preventing the absorption of moisture and the ill-effects as to change of volume and decay which would otherwise take place; it also prevents the bad effects of dry rot which follow the application of any surface treatment for preserving wood of the same type. The Marr process tends to drive out all water and makes the wood waterproof.

The North-Western Engineering and Supply Co. of Calgary are installing a 150 horse-power Babcock & Wilcox water tube boiler in their pumping and lighting plant at Drumheller, Alberta. This is the second Babcock & Wilcox boiler to be installed in this plant.

Exhibitors' Association Plans Representative Display

United Efforts of Manufacturers and Dealers Insure Interesting and Instructive Display—Industrial Power Conditions Impart Unusual Interest to Fuel and Labor-saving Appliances

AS in former years, a feature of the annual convention of the Association of Stationary Engineers will be the exhibition of power house apparatus, accessories and supplies which is organized by the Exhibitors' Association.

Events of the past year or eighteen months have served to convey with increasing seriousness the gravity of the present state of affairs regarding fuel supply and power resources. Taking place as it does in the midst of a district dependent almost entirely on outside sources of fuel and power, the convention and exhibition afford an admirable and timely opportunity for discussion of those questions which directly concern the welfare and prospects of stationary engineers along with inspection and investigation of the various appliances of which conduce toward the efficiency of the present day power house operator.

As indicated in a previous issue of POWER HOUSE the sessions will commence Tuesday, June 25, the opening ceremony in Hyman's Hall being performed by Mayor Summerville, following which, the appointment of the various committees will take place. The afternoon trip to Springbank Park will enable a close inspection of the pumping plant to be made, following which an entertainment by a select company of eminent artists will be offered the guests and members.

During the course of the convention addresses will be delivered by speakers on various subjects pertaining to the work of the members, including an address by Fred Raven, secretary of N.A.S.E., Chicago. In view of the organized efforts of power house engineers in the United States toward assisting in the national welfare the presence of Mr. Raven is looked forward to with considerable expectation.

Hyman's Hall is admirably suited for the double purpose of holding sessions and exhibition. Convenient of access from hotels, railroad depots and street car lines, it is located on a residential thoroughfare amidst pleasant surroundings, and much of the pleasure afforded members at the convention will be due to the conditions under which it will be held—the activities and labor of the local lodge under the secretaryship of Mr. W. G. Walters being worthy of due appreciation by all.

The Exhibitors' Association is under the presidency of Lieut. L. Archibald, of the Dart Union Co., who is at present overseas. As in former years, Mr. G. C. Keith, editor of the "Canadian Manufacturer," will discharge the duties of secretary, the other officers being E. F. Hetherington, Goldie-McCulloch Co., Galt, past president; C. N. Schrag, O. W. Meissner Co., Ltd., Toronto, first vice-president; Geo. E. Moll, hon. president, London; Jas. S. Mock, Jenkins Bros., Montreal, second vice-president; L. H. Dumage, V. D. Anderson Co., Cleveland, assistant-secretary; B. G. Newton, THE POWER HOUSE, Toronto, treasurer; C. B. Turner, Toronto; H. J. Ramshaw; Garlock Packing Co., Hamilton, chairman reception committee; Arthur Betton, Jas. Morrison Brass Mfg. Co., Toronto, chairman exhibition committee.

EXHIBITORS' COMMITTEE, C.A.S.S. CONVENTION, LONDON, JUNE 25-27.

NATIONAL ELECTRIC LIGHT ASSOCIATION CONVENTION

The thirty-fourth annual meeting of the National Electric Light Association was held at the Hotel Traymore, Atlantic City, June 13 and 14, and was devoted entirely to problems connected with the war.

No papers were read at this convention, and reports from committees and individuals and discussions were confined to matters of major importance. The brief time, two days, allowed no time to be taken up with the usual helpful discussions on general subjects relating to the progress of the art.

ANNUAL CONVENTION OF THE C. E. A.

The annual convention (28th year) of the Canadian Electrical Association will be held on Friday, June 21st, at the Chateau Laurier, Ottawa.

As this is a war-time convention, no entertainment will be provided, and the matters discussed will be principally confined to the effect of the war on the central station industry.

HYMAN'S HALL, LONDON, WHERE THE CANADIAN ASSOCIATION OF STATIONARY ENGINEERS AND THE EXHIBITORS' COMMITTEE HOLD THEIR 1918 CONVENTION AND EXHIBITION JUNE 25-27.

EDWARD CLARENCE MEIER, DECEASED

A large number of power house engineers and manufacturing firms learned with regret of the sudden death on May 7 of E. C. Meier, president of the Heine Safety Boiler Co. Mr. Meier was at Philadelphia attending a meeting of the district production division of the Emergency Fleet Corporation, and had made a short address regarding the speeding up of boiler construction. When he resumed his seat he was seen to fall forward in his chair, and was immediately removed to an ante-room, where a physician pronounced the body lifeless.

Edward Clarence Meier was born at Wyandotte, Kansas, in 1870, his father, Col. E. D. Meier having achieved distinction as founder of the Heine Safety Boiler Co., president of the American Society of Mechanical Engineers, and the leading spirit in the development of the present A.S.M.E. boiler code which is being rapidly adopted throughout the continent. Mr. Meier had worked through all the departments of the Heine Boiler Co., which was organized in 1884. The present plant at Phoenixville was established by the company in 1899 and Mr. Meier had been in charge of it up to his death. He was elected president of the company on the death of his father in 1916, and had been very active during the past year in designing a boiler for marine work.

M. C. Huyette, for 22 years with the Murphy Iron Works of Detroit, died at Buffalo, Friday, June 7, aged 75 years. The deceased was manager of the Buffalo office, and had charge of the Canadian business of the company. Despite failing health, due to heart trouble, he was active to the last, and had been in touch with the office the evening before his death.

Milton and Prentiss have formed a partnership in the business of engineering and machinery and power house

EDWARD CLARENCE MEIER

Late President of the Heine Safety Boiler Co., Phoenixville, Pa.

brokers, with offices in the Trader's Bank Building, Toronto. A. G. Milton was formerly of the Lincoln Electric Co. and later did business under the name of Archibald G. Milton, his special line being electricity. J. M. Prentiss, his partner in the new business, was for several years secretary of the Chartered Trust & Executors Co., for which concern he had charge of the winding up of the Interurban Electric Co., Ltd. He was also with the Power Plant Equipment Co., organized the Interurban Engineering Co., Ltd., and built and equipped an up-to-date machine shop on Vine Ave., West Toronto. The new firm have the agency of Schaeffer & Budenberg, for recording and pressure gauges and recording thermometers, also for steam jet ash conveyors, and other lines of interest to industrial plants.

W. H. Farrell, terminal superintendent of the Grand Trunk Railway in Toronto, has been offered and accepted the position of general manager of the Algoma Eastern Railway Co., with headquarters in Sudbury. Mr. Farrell will have charge of the line from Sudbury to Little Current, and will assume the duties of his new position on July 1st, Mr. Farrell has been in the Grand Trunk service thirty-four years, for twelve of which he has been superintendent of the Toronto terminals. The new general manager, like almost all successful railwaymen, started at the bottom, and by his untiring devotion to duty worked his way up to his present position.

P. O. D. Burke has been appointed inspector for the New Brunswick board of fire underwriters and will inspect sprinkler equipment and electrical installations throughout the province. He was formerly in the employ of the Nova Scotia Steel Company at Sydney Mines and came to New Brunswick as successor to Simon Skidmore, who was employed by the underwriters to inspect sprinkler installations, and who resigned to take up a position in Montreal on May 1. Mr. Burke, who is an expert electrician, will look after all special risks.

TWENTY-NINTH C.A.S.E. CONVENTION

CIRCUMSTANCES affecting the practice and profession of power house engineering continue to be influenced by events of the day, and during the last year much has happened to impress upon our fellow workers the necessity of the most rigid economy—first, last and all the time.

The convention of the Canadian Association of Stationary Engineers which takes place at London this month is primarily devoted to the affairs of that body. The transaction of business relating to statutory affairs—the discussion of matters affecting the welfare and advancement of members and their work—the consideration of present policy and the formulating of new, in order that the work of the Association may be of greatest benefit to the country as well as individuals—these constitute an objective which can only be partially reached in the three days available.

The value of such occasions for strengthening the bond of friendship amongst the members is well known to executives, social events and plant visitations forming an attractive portion of the events.

Graded certificates have become the object of increasing discussion with each successive convention and this, the 29th occasion, will be marked by official recognition of the efforts put forth by members in furtherance of this desirable object. Dr. Riddell of the Public Works Department of the Ontario Legislature is expected to speak on the subject and his remarks, as indicating the attitude of the government towards graded certificates will be heard with more than ordinary interest.

Little more can be said at this time on the certificate question. Its ultimate consummation in Ontario will be a matter for mutual congratulation by all parties concerned, and will remove the stigma which has hitherto attached to this province, which, although the foremost in industrial activity, was the last to recognize the necessity and justice of classifying power house engineers according to their ability.

Should the immediate future witness the settlement of the graded certificate question in the manner desired by all progressive and ambitious engineers, the convention of 1918 will be noteworthy for that feature alone.

PRACTICAL METHODS OF FUEL CONSERVATION

FACTORY owners in the United States are being actively assisted by the Federal Fuel Administration in the matter of effecting fuel saving.

The question of how much coal a factory can get is not any more important than knowing how to get the most heat from the coal after it is receivel.

The mode of operations is on somewhat similar lines to the "greater production" propaganda recently carried out. A board of competent engineers is recommended to be attached to a conservation committee in each State, while a corps of lecturers will be employed to arouse public interest and disseminate engineering information.

A fifty-minute film of moving pictures will demonstrate good and bad methods of operating steam plants while methods of testing boilers, fuels, etc., will be similarly dealt with.

The prospect of possibly harder times regarding fuel will make all factory owners and power users approve of such missionary work. Despite the prevalence of electric power in most Canadian provinces, the consumption of coal is plenty high enough to make imperative every possible economy of fuel. Where the fuel is used for heating a few degrees less in temperature mean a large difference in the coal consumption.

Many factories are over-heated in winter, necessitating the discard of some clothing by employees. Such conditions are criminal and their continued existence is a betrayal of the country's welfare. Such propaganda as outlined above should bring all parties to a sterner realization of conditions as they will actually be in the coming winter.

Preparedness and Efficiency are indeed the watchwords of the hour.

The Operators' Point of View

IS EXHAUST STEAM HOTTER THAN LIVE STEAM?—READERS' DISCUSSION

In reply to J. W. Maxwell's question, 'Is exhaust steam hotter than live steam?' I would like to state my experience.

I had always, prior to a year ago, pooh-poohed the idea that less exhaust steam would be required to heat a building than would be the case if live steam were used, but the proof of the pudding is in the eating.

A year ago, whilst carrying on alterations in my boiler plant I shut down the engines and took outside power. I only had one boiler in service for laundry, cooking and sterilizing purposes, and also for any heating that might be required. The first day was decidedly cool and I found it impossible to carry more than 50 to 70 lbs. of steam pressure on account of the great demand for steam heat. That night certain connections were made which gave hot water for the boiler feed, so that the next day there was a slight improvement, but at no time during the entire two days did we get more than 80 lbs. pressure instead of 125 lbs.

The third day was still cool, and the laundry man was hot (under the collar), so in desperation it was decided to start up two engines and run them light. This was done, and the live steam shut off the buildings, with the result that we got steam to every room in the building, whereas previously only the centre of the buildings was heated, and then not the two top floors.

Not only that, but the steam pressure rose until within an hour or so the safety valves blew off, so that actually more work was done with less coal by using the exhaust steam from the engines for heating in place of live steam. The engines were not doing any work but were only running fast enough to give a dull red light in the pilot lamps.

I do not pretend to explain why this should be, but the above is actual experience.

According to all theories that I have heard expounded, live steam, allowed to expand through a reducing valve (not doing any work during its expansion) is slightly superheated and is therefore more valuable for heating than is exhaust steam.

If we take 100 lbs. of steam at 125.3 lbs. pressure we have a total heat above freezing point of $1192.2 \times 100 = 119.22$ b.t.u. If this is expanded through a reducing valve to a pressure of 3.3 lbs. we obtain 100 lbs. steam at a temperature of 222.4 degs. F., having a total heat of 1154.2×100, which equals 115.420 b.t.u. But there are 3,800 b.t.u. unaccounted for.

As the steam has done no work in expanding it is impossible to imagine there could be any loss due to condensation, therefore it follows that the steam must be superheated.

If on the other hand we take 100 lbs. steam at 125.3 lbs. pressure and use it in an engine, we find that the engine will extract a certain amount of heat from it. In a good non-condensing engine taking say 30 lbs. steam per h.p., we should obtain, assuming the 100 lbs. of steam were used in one minute:

$$100 \div \frac{30}{60} \text{ h.p.} = 200 \text{ h.p.}$$

The number of b.t.u. extracted by the engine in doing work would be $200 \times \frac{33{,}000}{788}$ b.t.u. $= 8484$—778 being the mechanical equivalent of one b.t.u., so that the engine extracts only about 7.7 per cent. of the heat supplied to it.

However, if we add to the heat extracted by the engine the heat losses in the pipe, and the heat lost by cylinder condensation and radiation which will be about another 2½ per cent. or a little over, we shall have about 90 per cent. of the heat contained in the steam as it left the boiler available for heating.

In the case of live steam we have 119,220 b.t.u., and in the case of exhaust steam we have 107.298 b.t.u. Now figures cannot lie, but it looks in this case as if they were taking liberties with the truth. According to this illustration, live steam should be far superior to exhaust steam for heating, but the facts are to the contrary.

My own opinion, but which I submit in great diffidence, is that the pulsation of the engine exhaust drives the steam farther than does the steady flow of live steam through a reducing valve. I should like to have the opinions of some other of your readers on this subject.

Toronto. S. BALMFIRTH.

* * *

The question raised by Mr. J. W. Maxwell regarding live and exhaust steam heating has often been placed before me, and I would like to state that live steam is hotter in temperature than exhaust steam. But when it comes down to the heating of buildings, the exhaust steam is more saturated and will deliver more units of heat more quickly to the atmosphere and will maintain the coils or radiators at constant temperature, effecting a saving of 7 per cent. over live steam.

If it is desired to use exhaust steam for heating it is desirable to instal an asbestos covered receiver equal in diameter to twice the diameter of steam engine cylinder. This tank should be installed on the exhaust line 8 to 10 ft. away from the engine. This will maintain a constant flow of steam and will do away with fluctuation caused by the stroke of the engines. A back pressure valve is to be placed over the receiver and should be set at eight pounds.

Montreal. H. V. Smith.

* * *

The question has been asked as to whether or not exhaust steam is hotter than live steam. Some engineers claim that it is hotter and others claim that it isn't so hot. These claims are made because it has been thought or has been actually experienced that exhaust steam heats better than live steam.

According to the steam tables there is no difference whatever. At atmospheric pressure the temperature of steam is given at 212 degrees F. regardless of whether it is live steam or exhaust.

However, there is such a thing as superheating, and the question therefore resolves itself into these two: Is the live steam superheated? Is the exhaust steam superheated?

It is easy enough to place a thermometer in a pipe and measure the temperature of the steam. It would be interesting and good practice if more engineers would put thermometers here and there in their steam pipes and learn more about the temperatures of the stuff as it whizzes to and fro—in and out. I'll wager that a great deal will be learned about your plant by yourself or your engineer if this practice would be adopted. Thermometers don't cost much and in the end they might lead to some very important economies.

As for the live steam, we quickly become "suspicious" or interested in it and we are more liable to purchase a thermometer for measuring its temperature. Live steam sounds more expensive. But when it comes to exhaust the owner or engineer generally says to himself:

"Sure that's just exhaust steam and isn't good for much anyway, so why waste any money on a thermometer for measuring its temperature." That, in a nutshell, is the reason why so many of us overlook the value of exhaust steam. Too little is known about the heat contained in exhaust.

Is it likely that exhaust steam is superheated? Yes, and no. It all "depends." I have searched through voluminous treatises labelled Thermodynamics but didn't find the subject discussed, so will just point out a few probable reasons why exhaust steam is often or sometimes superheated.

In the first place steam enters a steam engine at high or fairly high pressure. The temperature is such as to correspond with the pressure as per our well known steam tables. As it enters the cylinder it heats the cylinder walls to about the temperature of the steam itself. Condensation occurs within the cylinder due to the imparting of this heat to the walls. During the expansion stroke some and perhaps all of this condensate is re-evaporated. Then dur ing the exhaust stroke the steam is pushed out past the hotter cylinder walls and through the hot exhaust ports which are kept hot by condensation and in the writer's mind it is quite possible that the exhaust steam is superheated. Where condensation is excessive perhaps the exhaust is not superheated. Never having made any tests it would be folly for me to declare that all exhaust steam is superheated.

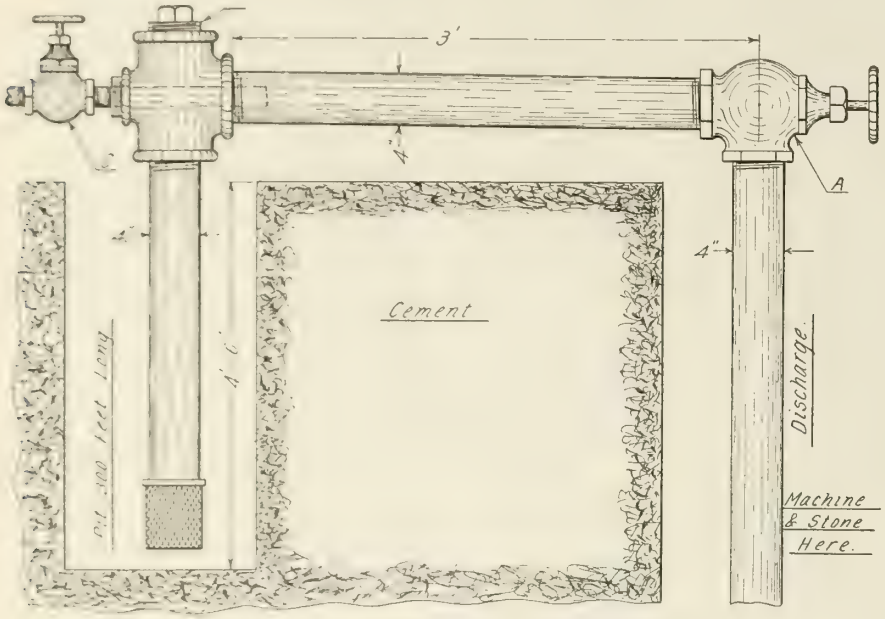
If the steam initially admitted into the cylinder is highly superheated, does it not seem quite probable that the exhaust may be superheated? True, again, much depends upon the point of cut-off.

Further, if the cylinder is steam jacketed and kept hot by live steam does it not seem quite probable that the exhaust will be superheated? I did find in the treatises through which I searched that one objection to steam jacketing is that a great share of the heat given to the jacketing is lost through the exhaust. If that is the case there must be a rise in temperature somewhere especially if the cylinder walls are kept so hot at all times that no condensation is formed.

It is well known that when live steam expands through an orifice as in a throttling calorimeter the steam on the low pressure side is superheated. It usually superheats to such an extent that the moisture contained in the initial is itself evaporated into steam and superheated. For the same reasons, to some extent at least, the exhaust steam from a steam engine or from a non-condensing steam turbine may be slightly superheated. If such is the case the suspicions of the engineers who believe exhaust steam to be better than live steam may be better founded than is generally believed.

This is a question that the writer has never seen discussed and he would like to read about some engineer's actual experiences. Or, he would like to be directed to some actual tests that have been made along this line.

W. F. SCHAPHORST.



SKETCH OF ARRANGEMENT FOR STARTING SYPHON.

SYPHON STARTER

By J. E. Noble

At the plant where the writer is employed there is a pit 300 ft. long and 4 ft. 6 in. deep, which receives a constant supply of strained sewage. After being treated with chloride of lime the sewage is syphoned into a machine, which travels back and forth the length of the building, i.e., 300 ft., being operated entirely by the syphoned water.

During its travel the machine discharges the sewage in the form of a spray over a stone-filter bed, 5 ft. deep, which covers the entire floor of the building, 60 ft. wide.

About once a week the machine has to be stopped for flushing out with clean water, etc, and the syphon breaks when the pit is emptied. To start the syphon again the valve A (see sketch) would be closed and the air extracted by a hand air pump placed on the tee at B.

In time the valve A leaked; it was refaced, but soon started leaking again. This was repeated until the valve could not be refaced again. By this time the air pump was almost worn out. Even when valve A and the air pump were both new it required from 15 to 20 minutes quick pumping to get the syphon started.

A plug was therefore placed in the tee at B, and a hole drilled in the back of the tee to take in a ½ in. high-pressure steam pipe having a valve outside at C. The 4 in. leaking angle valve was left on at A.

When the pit became full of water the valve C was opened and the valve A nearly closed, and inside of two minutes the syphon would start. The steam valve would then be closed and A opened wide.

KEY PULLER

By John Port

THE accompanying sketch shows a key puller which will prove satisfactory. When used with a suitable key drift and hammer the tightest keys will start.

Three pullers from light to heavy will handle about all the different sized keys to be found in any plant. The legs A and B can be lengthened or shortened to suit requirements by the nuts on the ends. The bolt C holds the puller leg against the key. Fig. 2 shows the centre leg or puller of different design. The puller is placed over the key head and bolt A is turned up, pulling the piece C over as far as the space at B will allow.

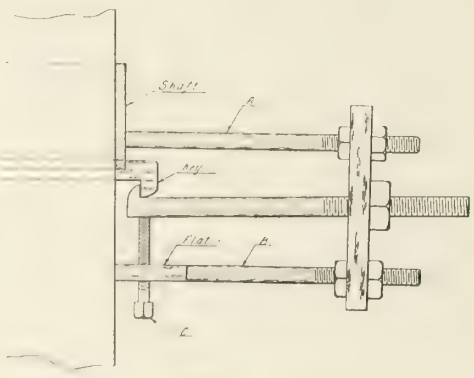


FIG. 1.

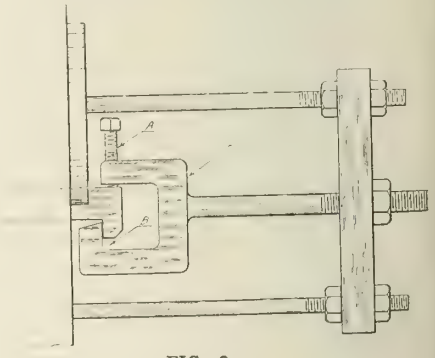

FIG. 2.

SETTING VALVES ON DUPLEX PUMP—READER'S QUERY

Replying to your correspondent's inquiry regarding the setting of valves on a duplex pump, it is only necessary to get everything central—that is, to set all the moving parts in mid-position.

To do this proceed as follows:

Remove both steam chest covers.

Push one piston to the extreme end of its stroke, and mark the rod where it enters the stuffing box, say, at the steam end. Push it to the other end of the stroke, and mark again at the steam end. Divide the distance between these two marks and mark the rod again at this point. This is the mid-stroke mark, which is to be set at the edge of the steam cylinder stuffing box.

Do the same with the other rod. Then with both piston rods set at mid-stroke, set the rocker arms in a vertical position. If necessary use a plumb bob.

Then set the slide valves in mid-position—that is, just covering the steam ports. If the lost motion between the nut on the valve rods and the lugs on the valves is not the same on both sides of the nut make it so by screwing the rod in or out of the nut as required. This is all that is to do to set the valves of a duplex pump.

In case of excessive wear in the valve gear some of the lost motion on the valve rod may be taken up by placing a washer on the rod next the nut until the valve gear is repaired or renewed.

Toronto. S. BALMFIRTH.

EVERYBODY HIS OWN MOULDER

By J. E.

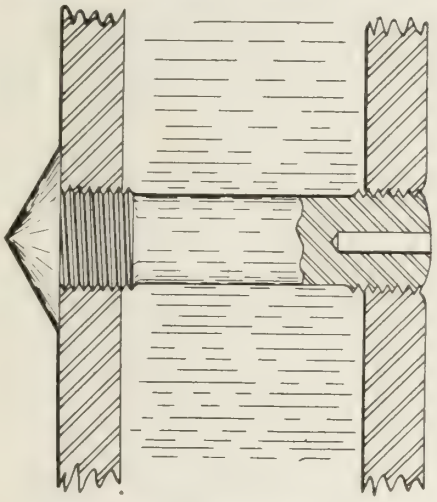
While conversing with a brass moulder a short time ago, I was given some valuable information, likely to be of considerable help to most mechanics. He described to me a method for making castings of brass or copper as easy to melt and run as lead. In special places the plumber can have brass or copper tacks to solder on his waste. I confess there are very few lead tacks used now, but I remember the time when I used hundreds of them. The jobber can run copper or brass name plates in the ordinary brass mold, such as is used to run lead tacks. The engineer can make plumb bobs from the metal, castings with holes can be filled with the metal and look as solid as a rock, and hundreds of other uses can be found for it. Here are the details.

Secure a quantity of brass or copper filings, dissolve a quantity of sheet zinc in about a cupful of muriatic acid, and add about a cupful of water. Place a quantity of either of the filings in this dilute zinc chloride to clean them. As a binder, melt nine parts of lead to one part block tin; remove the filings from the acid mixture, and place them somewhere so that they will dry out fairly quickly without getting hot enough to burn or tarnish. Now stir the filings into the lead and tin in about the same proportions as the former—that is, nine parts of filings to one part of the binder. Sprinkle a little rosin in with it. It will become one complete mixture, which will run as freely when heated as a pot of lead on a gasoline furnace or even over a wood fire. This metal can be made into castings and turned in a lathe, and it will require close examination to detect the counterfeit. When made into such things as plumb bobs, etc., a brass or copper surface can be secured by a slight rubbing over with fine emery cloth or sandpaper and polishing with whiting or any other polishing agent. Of course, this metal can not be used on anything which will be subject to a strong heat, as its temperature of fusion is about the same as lead.

REPAIRS TO STAYBOLTS ON VERTICAL BOILER

By A. Rodgers

A recent repair on a small vertical boiler reminded me of a job that was successfully accomplished by the writer a number of years ago. The work required was the stopping of several leaky staybolts. Several attempts had been



REPAIR TO STAYBOLT.

made to stop the leak by caulking, but with very little result. The writer was then placed on the job, and the method adopted was as follows. As illustrated in the sketch, the fire end of the staybolt had been so badly burnt that nothing remained of the riveted section; in fact, the portion near the thread had been destroyed below the level of the main plate. As the two shells were of cylindrical form it seemed to me that there was little need of staybolts anyway, so decided to leave the old bolt in position and remedy the trouble by expanding the thread of the bolt into the thread in the plate. By means of a ratchet and a ¼ inch drill the small hole shown was made in the center of the bolt, after which a small slightly tapered drift was inserted and the metal of the bolt gradually expanded until the leak was entirely stopped. When this was attained a small steel plug was driven into the hole and locked by slightly riveting over the end of the bolt. The repair proved very satisfactory and showed no signs of leaking even under excessive pressure.

READER'S QUERY

Question.—I have been given several samples of oil to test and would like to be given a simple method of determining which is the best.

Toronto. G. M.

Answer.—The most important qualities which permit of easy comparison are vicosity, low coefficient of friction and wearing powers. As a means of determining these properties the following test is recommended:

Take a piece of glass, preferably plate glass, about fifteen or eighteen inches long whichever happens to be handy, and also a disc of glass about 10 sq. ins. in area. Load this small disc with sufficient weight, determined by trial, to insure its sliding on the large glass when the latter is tilted and covered with the lubricant.

In testing out the oils take a small definite quantity of each oil and test these quantities out in rotation by thoroughly spreading the oil on the disc and on the glass slide. Then slowly tilt the glass until the loaded weight begins to slide and observe this angle for each sample. Then tilt the glass farther and let the disc travel to the bottom and repeat until the disc refuses to travel further. Be sure after each oil is thus tested to clean off both disc and plate thoroughly before trying out another sample.

The different angles at which ahe disc starts to slide for different oils will give a comparative measure of viscosity and coefficient of friction, and the number of times that the disc travels down the plate before it sticks gives an indication of its wearing and lasting powers.

BOILER SERVICE MAINTENANCE

A boiler is in a dangerous condition when the plates, bolts, braces, or rivets of which it is constructed become weakened to such an extent that the internal force or pressure equals the tensile strength of the material at the weakest section or sections. In this condition, strains due to varying temperature will cause rupture and an explosion, the volume and destructiveness of which would be in accordance with the size of the boiler and the pressure carried therein.

The moment a boiler is placed in service it gradually becomes weaker, due to the destroying forces continually acting upon it. These forces are of both a chemical and mechanical nature. Corrosion and oxidation are continually acting on the material from which a boiler is constructed, and take place both internally and externally, these processes being the two most serious and subtle causes of weakening to which a boiler is subjected. Evidences of these are most noticeable in the grooving and pitting of plate, and more especially at locations most subject to deposits of mud, scale, and organic substances.

Expansion and contraction also play a very important part in the destruction and weakening of a boiler, more especially when concentrated at any one point, such as at sharp bends or flanges in the plates where the inner and outer

sheets are subjected to different temperatures. Constant working or bending of bolts, flanges, or angles, however slight, will sooner or later destroy the fibres in the material at points subjected to it, causing crystallization, cracking, and leaving same more susceptible to the chemical action of the feed water.

It is, therefore, obvious that only thorough examination by competent inspectors who understand the construction, nature of defects, and remedies to be applied, will maintain a steam boiler in safe working condition.—"Cheap Steam."

ACCIDENT PREVENTION

By J. Hamilton

Industrial accidents must always be recognized as one of the possible factors in any mechanical development or enterprise. Much has been done during the past, particularly in recent years, to minimize the casualties resulting from inexperience, carelessness or accidental causes. It is safe to say that the greater proportion of accidents to industrial workers has resulted from individual carelessness or thoughtlessness, either on the part of the injured workman or some other party. Close study on the part of officials and safety supervisors —relative to the causes and prevention of accidents—has resulted in the adoption of many appliances that have assisted in reducing the size of the casualty lists in industrial establishments.

The efficiency of the majority of these devices, however, depends very largely on whether the same are acceptable to the workmen, who are required to adapt themselves to the changed conditions. It is invariably true that the application of a safety device will, for a time at least, prevent the operator from maintaining his accustomed production, and should he be working on a piece-work basis, the loss very often develops an antagonistic feeling towards the appliance indirectly responsible, so that it will not receive the just trial it is reasonably entitled to. Frequently the device is discarded as an obstruction to production until another mishap demands its further application.

When guards are mentioned as a means of reducing or preventing accidents we naturally think of some tangible appliance for the purpose intended, but the most efficient guard for permanent results has been acknowledged as the better education of the workmen respecting the serious possibilities that may arise through careless or thoughtless performance of their respective duties. This does not imply that instruction should take the place of safety appliances, but rather that the adoption of such devices should be preceded by personal consultation with the workman upon whose machine the method is to be applied. The conversation should be such as to impress the operator with the need of the device, and at the same time make him feel that his interests are being considered; obtaining, if possible, any suggestions he has to offer in connection with the design or installation of the attachment. His constant operation of the machine may result in a suggestion that may have been overlooked by the designer, and a slight change made to meet the suggestion of the workman may not only remove an antagonistic tendency but would undoubtedly act as a stimulus for the operator to give the device every opportunity to prove its effectiveness.

ENGINE ROOM RULES

Employees should be strictly forbidden to enter the engine room except for a special mission, and then should remain only as long as necessary. The engineer should not be permitted to leave the engine room until some other attendant who is thoroughly familiar with the engine, valves and signals is present to take charge.

No person other than those responsible for the operation of the engines should be allowed to touch any valves or other part of the mechanism or approach any moving part.

The safe speed for each flywheel should be known, and in no case should this be exceeded. Flywheel revolutions should be recorded every day in order to make sure that the engine is not running over the speed limit.

All parts of engines and accessories should be frequently and thoroughly inspected, and daily tests should be made of the governor mechanism and automatic engine stops.

Under no circumstances should engines be started until they are thoroughly cleared by alternately blowing live steam through each end of the cylinders, and the steam pipe and cylinders thoroughly drained of all water. The drip should be left open until the load is put on and then closed. Be sure to warm the engine cylinder at both ends.

In shutting down, the drip valve should be left closed until the engine is stopped. If the throttle is equipped with a bypass valve, the throttle should be closed and engine stopped with the bypass. This gradually stops the engine, avoids the pumping effect of the piston and prevents water being drawn into the cylinder.

Never attempt to "bar" a flywheel around, nor pull it off centre by grasping the belt when the steam pressure is on.

Never start to take cylinder head off or piston out of cylinder without making sure that the throttle and exhaust valves are shut tight and locked and the drains wide open; nor without trying the indicator cocks to see whether there is any pressure on.

Never stop the air pump before stopping the engine (condensing), as the condenser and exhaust pipe may be flooded and overflow into the cylinder.

All steam traps should be kept clean and in working order. Should a trap get out of order, and it be impossible to repair it at once, the bypass should be opened sufficiently to pass off all water which might collect.

Leaks in pipes, flanges or gaskets should be repaired at the earliest possible time.

In opening up a cold line, all available drips should be opened. The line should be warmed by opening the bypass where possible or by opening the stop valve sufficiently to warm very slowly. Never open the main valve until certain that the line is thoroughly heated. An inexperienced attendant should not be allowed to turn steam into a cold line until properly instructed.

Automatic valves should be frequently examined to insure their proper action in emergency.

Under no circumstances should vacuum breakers, governors, engine stops or other safety devices be blocked or otherwise made ineffective. If such apparatus is out of order, it should be repaired at once.

Do not stand in front of cylinder head of engines.

Do not place any material, tools, etc., on platforms or stairs around engine. They might fall off and injure someone below.

Never work in a gas-engine room alone; always have a helper with you.

If you find a man overcome with gas, get him into the open air at once, send for the doctor and notify the foreman.

Smoking and open lights should be forbidden around gas machinery and gas pipes; otherwise an explosion might occur.—The National Safety Council.

A NORWEGIAN engineer has devised an ingenious method of reducing the cost of paper manufacture by utilizing the residue from the mills, which produces a fuel to run the plant. The paper pulp obtained from wood constitutes only 45 per cent. of the wood, and the residual 55 per cent. has hitherto been found useful chiefly for the wood alcohol and acetic acid obtained from it by distillation. This engineer has recently patented and perfected a new process by which the residue furnishes a fuel in the form of a powdered coal, or charcoal, which evolves great heat in commbustion. The first plants have been erected at Greaker, on the Christiana fojrd, and it is estimated that they will shortly be able to yield an annual output of 6,000 tons of this new fuel. This will suffice to supply all the cellulose plants in Greaker with an inexpensive fuel, and at the same time it rids them of a burdensome encumbrance. Since the total production of paper pulp in Norway is estimated at 1,000,000 tons yearly, doubtless other plants throughout the country will soon be similarly equipped.—M.L.

THE task of the power plant engineer can be materially lightened by the use of an electric recorder which records the level of the boiler water at all times. This instrument indicates where the water is, where it has been and the time in each instance. It is provided with high and low alarms in the form of lights and bells. A light burns continuously when the boiler water is on the economical line.—C. T.

Progress in New Equipment

WHY CAST IRON PROTECTS SOOT CLEANER ELEMENTS AGAINST HIGH TEMPERATURES

Although steel, wrought and cast iron are used more than other metals in engineering works, there are few engineers who can tell what effect high temperatures have on them as regards strength.

Tests have been made mostly in Europe, but the results of those tests have been buried in dry, voluminous reports or in foreign language literature. These tests have recently been sought and collected by the Vulcan Soot Cleaner Co., of Du Bois, Pa.

Permanently installed soot cleaners must often be placed in temperatures that are comparatively high and for that reason the above manufacturers have investigated the matter with thoroughness. Their study, experience and conclusions will doubtless prove of interest to all who have anything to do with steam boiler operation.

Most laymen are aware of the fact that when metal is heated to a high temperature it bends easily. When "red hot" they know it is forged easily. And when still hotter it becomes liquid. But these phenomena are not associated with decrease in tensile strength. Yet it is this decrease in tensile strength that permits the metal rod or pipe to be bent or broken easily and that is why tensile strength tests are so important in this discussion.

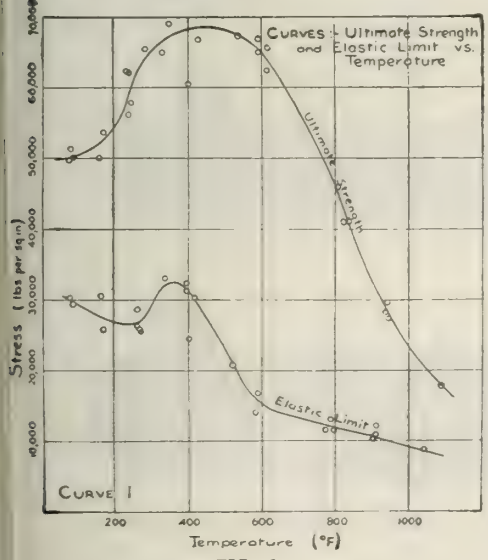


FIG. 1.

On the other hand, it is commonly believed by engineers who have given more thought to the subject that steel and wrought iron become weaker with increase in temperature. But that is not strictly true, and therein lies a point of considerable interest.

Steel and cast iron both grow stronger up to a certain point as shown by the ultimate strength curves in Figs. 1 and 2. Thus the maximum strength of wrought iron occurs at a temperature of 50 degrees F. whereas the corresponding temperature for steel is about 525 degrees F. However, with further increase in temperature the curves show that ultimate strength decreases rapidly. These figures also give the elastic limits of wrought iron and steel at high temperatures and the curve relation between elastic limit and ultimate strength.

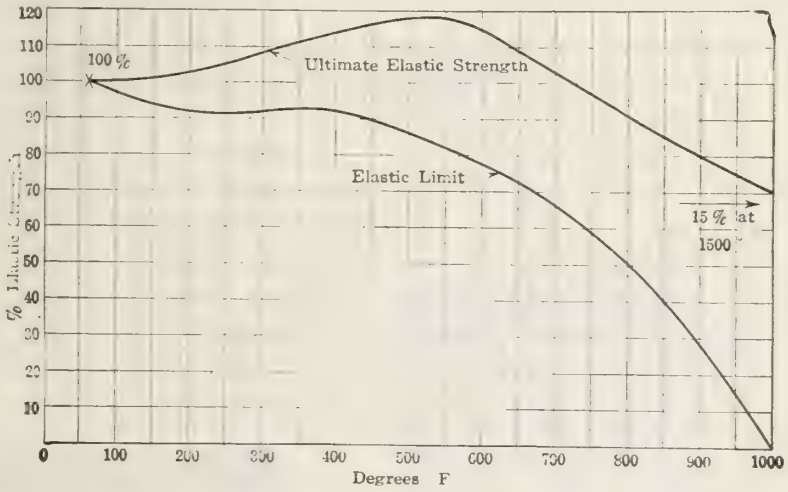

FIG. 2.

Fig. 1 shows that the ultimate strength of wrought iron drops very rapidly when the temperature is in the neighborhood of 1000 degrees F. and Fig. 2 shows that at the same temperature, steel no longer has an elastic limit. In other words, if soot cleaner elements are made of steel alone, and if they are heated to a temperature of 1000 degrees F. they are liable to sag due to their own weight and become inoperative in a short time.

The maximum temperature to which soot cleaner elements are subjected is not definitely known, but it is doubtful if the temperature of the metal itself ever passes 1000 degrees F. even though the temperature of the hot gases is 1500 degrees F. For example, a test made by A. W. Conklin shows the temperature at the top of the first pass in a hand-blown boiler to be 954 degrees F. In the same boiler, cleaned by a permanently installed cleaner, the temperature at the same place was reduced to 934 degrees or a difference of 20 degrees in favor of the mechanically cleaned boiler. Thus the mechanical cleaner protects itself in providing for itself a minimum temperature. Even at points close to the fire near the bottom of the first pass, there was a temperature difference which favored the mechanical cleaning method. Although it may sometimes be necessary to place soot cleaner elements in gases having a temperature of 1500 degrees F. as for instance in the first pass of a B. & W. boiler, it has not been found difficult to maintain a temperature in the cleaner elements of less than 1000 degrees F. by means of dead gas pockets, baffle screens, etc. Convection currents are thus warded off and by placing the elements in close proximity with the boiler tubes, which seldom if ever have a temperature higher than 380 degrees F., the temperature of the element is kept well within the bounds of safety by radiation.

It has been stated by such authorities as Kreisinger and Barkley that in taking temperatures of gases, surrounded by colder or hotter surfaces, there is usually an error of some 3 to 25 per cent. in temperature. This error is due to radiation. Quoting from "Finding and Stopping Wastes in Mod-

ern Boiler Rooms Vol. II" by the Harrison Safety Boiler Works:

"If a temperature measuring instrument is immersed in hot gases surrounded by cooler surfaces, it absorbs heat by convection, and its temperature rises. Gases are permeable to radiation and as soon as the temperature instrument exceeds that of the surrounding surfaces, heat passes from it to them through the gases by radiation. The temperature of the instrument continues to rise with a decreasing rate until the quantity of heat it gives off by radiation is equal to the quantity is received by convection. The temperature then remains constant, but is below the temperature of the gases. The magnitude of the error depends mainly on:

(1) The size of the part of the instrument exposed to the gases and the radiation.

(2) The difference between the temperature of the gases and that of the surrounding surfaces.

"The smaller the exposed part and the smaller the difference of temperature, the smaller the radiation error."

Rules 1 and 2 are applicable to a soot cleaner element as well as to a thermometer. Thus according to rule 1 it is advantageous to make the element large. And according to rule 2 the difference in temperature, perhaps 600 degrees or 700 degrees F. at times, serves as a further protection.

Thus it has been found that the elements are seldom if ever subjected to a higher temperature than 1000 degrees F. However, to make assurance doubly sure, the manufacturers decided to make the Vulcan cleaner safer and longer lived by reinforcing the element with a metal sheath that is not easily influenced by heat.

A study of pages 543, 544 and 545 of Marks' Mechanical Engineers' Handbook will soon convince anybody that there is no better metal for this purpose than cast iron. Among the various metals listed are alumnnum, bronze, phosphor bronze, cast manganese bronze, malleable iron, cast steel, cast nickel, Monel metal, machining steel, metal vanadium steel and rolled Monel metal. All of these metals lose their strength very rapidly when the temperature is in the neighborhood of 1000 degrees F., but it is shown that soft cast iron and strong cast iron both retain their strength remarkably well.

Fig. 3 is plotted from the test data given in Marks' Mechanical Engineers' Handbook for strong and soft cast iron. These curves tend to show that cast iron grows stronger up to a temperature of about 450 degrees F. and from that point on the strength reduces slightly. The strength of soft cast iron, it will be noted, is practically constant all the way from 100 degs. to 1,000 degs. Fahr.

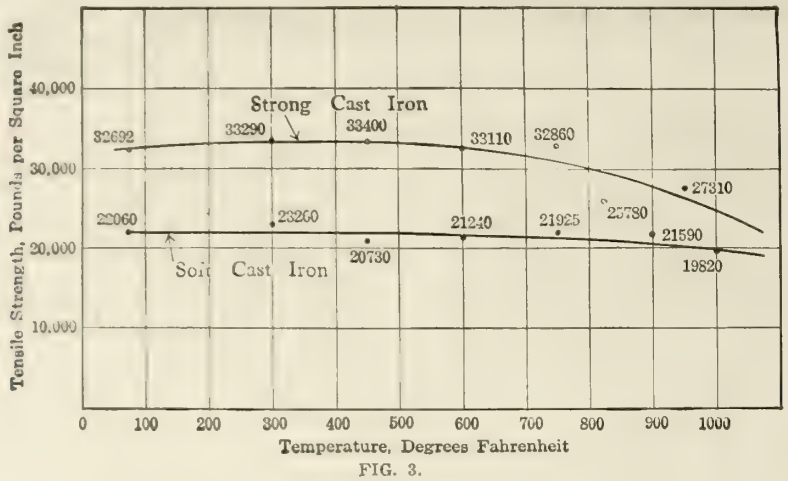

FIG. 3.

From these curves the conclusion may be drawn that cast iron of almost any good composition will protect soot cleaner elements sufficiently. But a specially uniform grade of cast iron has been decided upon and is now being used.

Also, inasmuch as the cast iron sheath placed over the soot cleaner element makes the element somewhat larger, it is evident that the rate of radiation will be greater, according to one of the rules quoted above. The greater size, therefore, insures lower temperature.

Cast iron also has a high heat radiating factor. Marks' handbook gives the following factors for the several substances: Cast iron, rough, oxidized, 1570; lamp black, 1540; wrought iron, dull, oxidized, 1540; lime plaster, rough white, 1510; water, 1120; wrought iron, highly polished, 467; brass, dull, 362; copper, slightly polished, 278.

To further emphasize the value of cast iron for retaining its strength at high temperatures take for example the well known comfortable, red hot, cast iron stove. Have you ever stopped to consider the strength retained by the metal, even at the high temperature of a good cherry red (1,500 degs. Fahr)? Moreover, you recall that the top of the stove does not scale or burn.

All engineers are quite familiar with the use of cast iron in grates where temperatures go very high.

In the field of steam engineering we are all familiar with super-heaters that have cast iron rings placed upon the inner tubes of steel, these being used principally to strengthen the structure at high temperatures which prevent overheating and warping. These superheater rings do not scale or burn.

We are also told of a case in a steel foundry where certain cast steel parts for furnace cage which was used to transfer the part to be annealed in and out of the furnace fell down repeatedly. The foundry was employed in making castings of steel only and the parts that were failing were finally sent out to be made of cast iron, and thereafter proved entirely satisfactory and resisted warping under the high temperatures to which they were necessarily exposed.

An editor of "Metallurgical and Chemical Engineering" wrote the following:

"Cast iron is better than wrought iron or steel for purposes where the material is subjected to considerable heat. Most steel is heat treated, and if subjected to considerable heat in practice it will lose to some extent the properties which were given it by the heat treating. Cast iron contains a much larger percentage or carbon than either wrought iron or steel and retains its properties up to quite high temperatures."

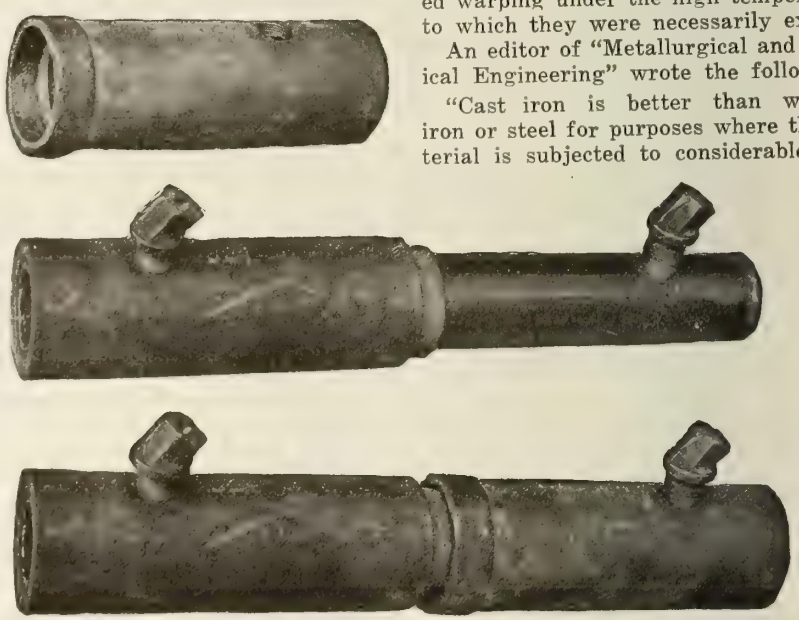

FIG. 4—SOOT CLEANER ELEMENT AND CAST IRON PROTECTING SLEEVE.

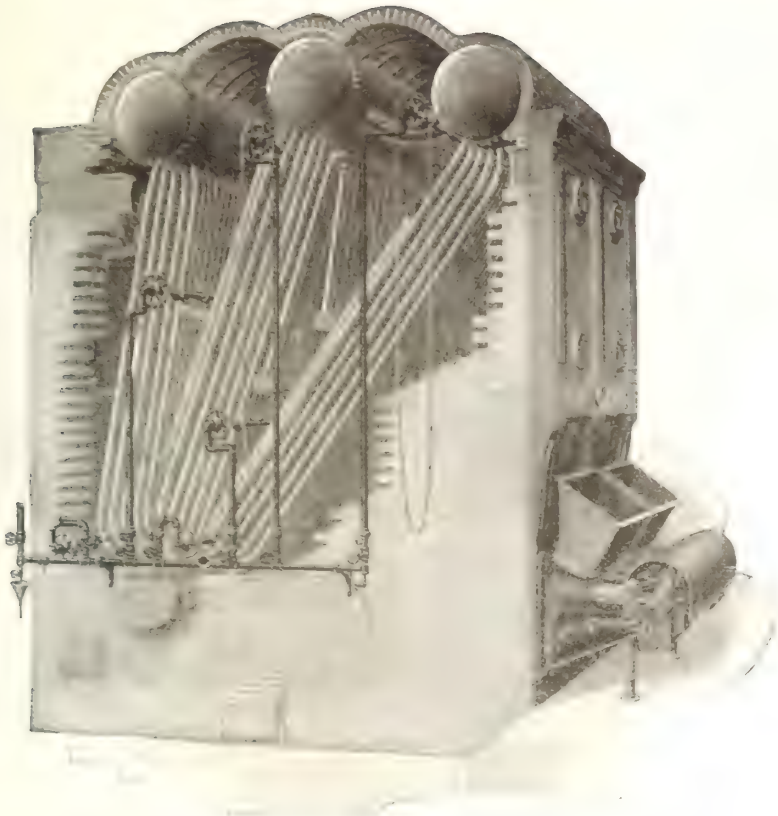

FIG. 5—SOOT CLEANERS INSTALLED IN BOILER SETTING.

Cast iron is used in Diesel engine cylinders, for example, where steel would not stand the strain.

Cast iron has an additional important advantage because of its resistance to corrosion. It is well known, for instance, that there are a great many cast iron economizers which have been in successful operation for fifty years. Cast iron is used for pipes under all sorts of conditions, in underground work, in water, in out-door exposures, subject to acid fumes, etc. We are all familiar with the cast iron pipe advertisements showing examples of pipes that have been in active service for some 100 to 200 years without evidence of serious corrosion. Cast iron forms a scale on its outer surface which seems to act in a protective manner, and besides, the crystal construction of cast iron itself is effective in resisting corrosion.

Fig. 4 illustrates how the problems of designing these non-warping sheathed elements was approached. The steel inner pipes in the element are wholly encased in the heavy cast iron sheaths with a loose fit. Fig. 4 is a short length of a standard element for horizontal tube boilers. Above the assembled view is shown the same element with part of the sheath removed exposing the inner steel tube. This photograph also shows the arrangement of nozzles for blowing down obliquely.

Fig. 5 shows a soot cleaner installation adapted for vertical tube boilers. It is similar to Fig. 4 except that its nozzles are at right angles to the element and not oblique. This element is located between the circulating tubes above the first pass in boilers of the type illustrated in Fig. 6 where the tube arrangement is such that the nozzles discharge at right angles to the element.

AUTOMATIC STARTERS FOR DIRECT CURRENT MOTORS

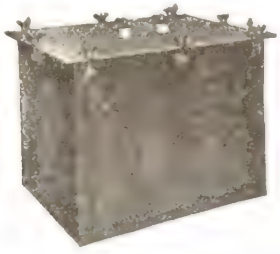
A SIMPLE and reliable means of controlling direct current motors from remote points is offered in the automatic starters manufactured by the Canadian General Electric Co. and illustrated herewith. These starters are particularly advantageous when used with motors

OIL TANK PARTIALLY REMOVED FROM AUTOMATIC STARTER FOR INSPECTION.

which are required to start and stop frequently, and may be applied to either shunt or compound wound motors.

All contactors are designed for heavy duty. The operating coils of the line contactors ,as well as the coils of the smaller accelerating contactors are wound with enameled wire and impregnated for moisture proofing. On the larger sizes coils are wound edgewise with heavy copper ribbon.

The main circuit is made and broken on solid copper contacts provided with magnetic blow out and arc chutes. The starters provide current-limiting acceleration which always starts the motor



OIL IMMERSED AUTOMATIC STARTER

quickly on light loads and slowly on heavy loads.

The terminals are plainly marked and the line, motor and control connections are made on the front of the panel, thus facilitating installation.

These automatic controllers are recommended for use with motors driving centrifugal or rotating machinery, air compressers, blowers, etc., or any machinery where automatic starting is desired and

A MODIFICATION OF THE STANDARD REMOTE CONTROL STARTER HAVING THE LINE SWITCH FUSES AND OVERLOAD RELAY MOUNTED ON THE PANEL.

may be operated by a float switch pressure governor or other switch.

Where fire hazard is prevalent these controllers are supplied of the oil immersed type.

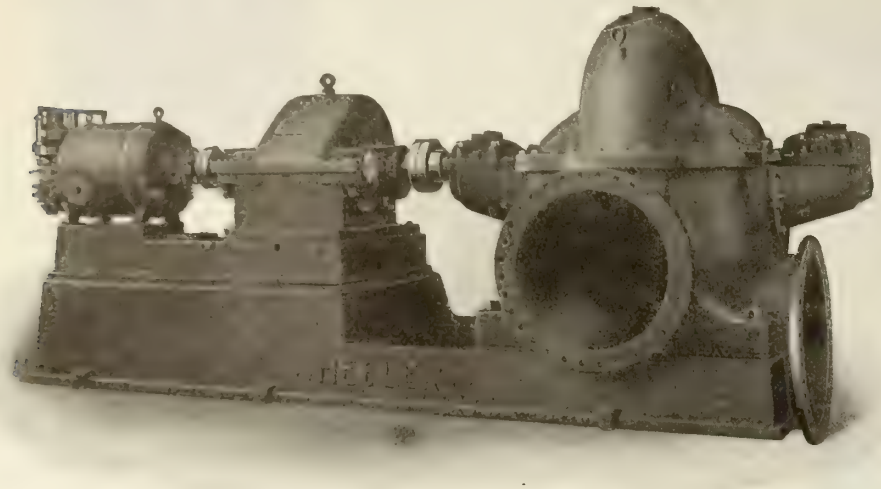
All starters are provided with either under-voltage release or under-voltage protection. The under-voltage release provides that in case of failure of voltage the motor will automatically restart on return of voltage. Under-voltage protection provides that in case of failure of voltage the motor will not start upon return of voltage until the starting button is pressed. Overload protection is supplied by an instantaneous hand reset overload relay which opens the closed circuit on overload. An electrically reset relay can be supplied if desired.

A NEW END SUCTION CENTRIFUGAL PUMP

A NEW design of pump manufactured by the Wheeler Condenser and Engineering Co., Carteret, N.J., is illustrated herewith. This pump is of unusual interest because of the unusual position of the suction opening which is directly

beneath and parallel to the end bearing. In this position it is out of the way, yet in a convenient place for the erection man for inspection and for upkeep.

This arrangement makes it possible to place a pumping unit in a room of small ground area—considerably smaller than where the suction end is opposite the outlet end as is the most common practice. In many cases this also facilitates the making of pipe connections, sometimes saving elbows and reducing the length of piping more or less.



STEAM TURBINE DRIVEN CENTRIFUGAL PUMP WITH END SUCTION ADAPTED TO CONDENSER PRACTICE

The capacity of the particular pump shown is 45,000 gals. per min. against a head of 20 ft. The diameter of the outlet pipe is 36 inches. The speed of the pump is 240 r.p.m., and it is coupled by a 10 to 1 reduction gear to a steam turbine whose speed is 2,400 r.p.m.

LARGE EXHAUST RELIEF VALVE

ONE of the largest relief valves ever manufactured is illustrated herewith. The illustration gives a good idea of its relative size. It is a 48-inch horizontal exhaust relief valve, and is hydraulically operated, and serves as a safety relief for the condenser on a turbine unit.

The complete valve weighs 4,000 pounds and measures 7 feet 5 inches from face to face of flanges. The valve disc, 48 inches in diameter, is made of cast iron, and has a bearing metal face which seats on a brass ring. It is water sealed, and is double cushioned with brass-lined dash pots above and below the disc. The valve stem is 3½ inches diameter. This valve is the latest addition to the valves built for the Detroit Edison Co. by the G. M. Davis Regulator Co., Chicago.

IMPORTANT RADIUM DEVELOPMENT

More than $180,000 worth of radium for use in the sciences has been delivered to the Bureau of Mines at Washington under an agreement between it and the National Radium Institute to develop a more efficient process for the manufacture of radium out of the carnotite ores of Colorado and Utah. It is stated that the amount of radium in question was procured for an expenditure of less than the amount of radium in question was $38,000. In addition, under the agreement, the bureau has turned over to the National Radium Institute about 6½ grams of radium, and has given to the country a method for producing pure radium compound from the ore for one-third the current price of radium.

When the Bureau of Mines began this work in 1912, it found that the precious carnotite ores, constituting the largest known supply of radium ore in the world, was going to Europe, mainly to Germany where it was being turned into radium and sold back to the United States at fabulous prices.

THE question of the most advantageous way of cooling a car is surrounded with a number of considerations due to the circumstances underwhich the car is employed, and consequently it is impossible to say what would be the best course to adopt until all the qualifying conditions are examined. In South Africa it was found most convenient to cool brine at the termini and run this brine into coils on the top of the cars. For Russia, with the long journeys from Siberia to the capital, it was ultimately decided as the result of long and careful tests that iced cars were the most suitable. On the Eastern Bengal State Railways a similar conclusion has been arrived at, provided the character of the insulation were suitable. Experimental vans were built to deal with the fish traffic from Sara and Goalunda to Calcutta, and at the same time the carriage of fruit was considered. In connection with the latter it was found that the carbon dioxide given off by the fruit hastens its decomposition, necessitating special means of ventilation.

Cork slab insulation was tried, but after using it and other materials the consideration of effectiveness, weight, and cost, resulted in the use of "Sunsul" (*Bombox Malabarium*) which is a variety of cotton tree common in India. It is said also to be only slightly absorbent of moisture. The insulation consists of 12-in. to 8-in. of non-conducting material, with ice compartments at one or both ends. Electric fans circulated the air previous to loading as well as on the journey, the temperature being reduced from 90 deg. Fahr. to 48 deg. or 42 deg. Fahr. in twenty-four hours. It was found that the temperature rose practically one degree in four hours.

Arrangements have been made to run the railway cars with various types of refrigerating machine either direct driven, or by means of electric motors taking current from a generator driven from the axle, and in some cases whole trains have been cooled from one of the cars fitted with the necessary machinery. —*Refrigerating World.*

LARGE EXHAUST RELIEF VALVE.

The Lack of a Grease Extractor Cost Them $5,000.00

We can't give the actual name of the college power plant at which this neglect took place.

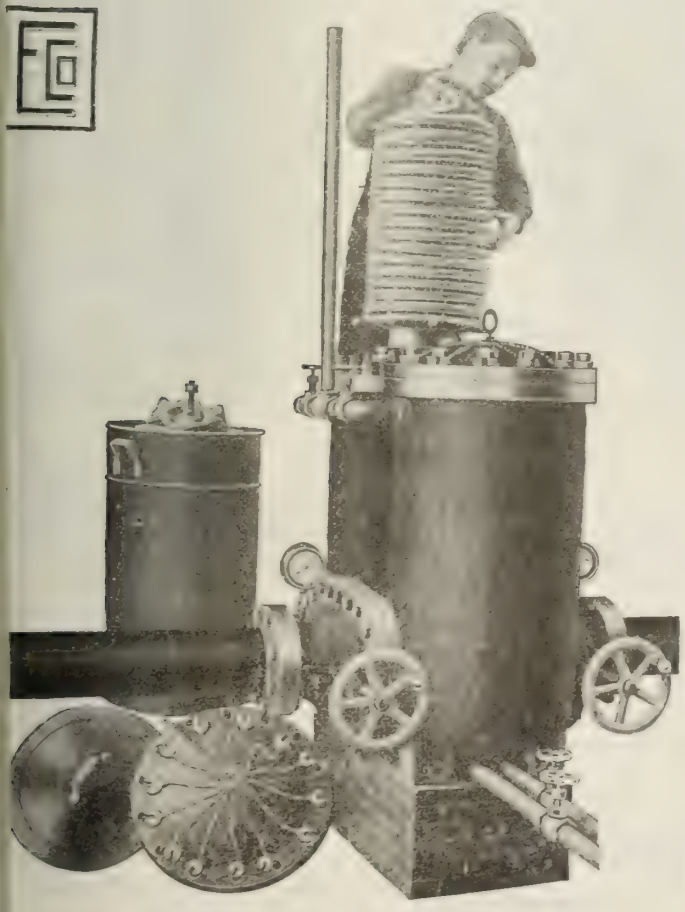
Naturally no plant wants to be connected with a true story like this.

But here are the facts:

Oil was allowed to get into the boilers and four of them were ruined by sagging—it cost $5,000—get that, five thousand in cold cash to reset these boilers.

With the reset boilers, a Twin Grease Extractor was installed and—

They have had no trouble since.



The Twin Filter and Grease Extractor

Avoid the Danger of This—Install a Twin Grease Extractor

This actual case proves again how much better it is to use the ounce of prevention. Keep oil out of your boilers thoroughly, efficiently, safely, with a Twin Grease Extractor.

You'll find unusually good features in the "Twin." For instance, you can clean it easily—a very important point. But more important, the twin idea; two separate filtering chambers—while one is in service, the other can be cleaned without by-passing or interrupting the flow of water.

You'll find a complete description in our Bulletin B. Send for a copy.

TRADE GOSSIP

Chicago.—A portable track welding outfit weighing less than 200 pounds which takes its power from trolley wires has been invented for small street railways that do not require elaborate equipment.

Renfrew.—The town council, through the waterworks' committee, has decided to purchase a twin horizontal enclosed turbine waterwheel, and a 12-inch two-stage pump. It is practically a duplicate of the present outfit. Some idea of the way prices are increasing can be gained from the fact that the present price quoted is $1,244 over the quotation of October 23, 1917, and $1,640 over that of July, 1917.

To Build Briquette Plant.—It is announced that the federal government has sanctioned the plan whereby a plant for the manufacture of briquettes from lignite coal will be established in the Estevan district. The federal government will provide $200,000, and Manitoba and Saskatchewan each $100,000. This plant will be erected as soon as possible, and may prove a factor in the solution of the pressing fuel problem.

Detroit.—Henry Ford has this to say of the much-discussed Liberty motor; "It is a wonderful creation. It is undeniably the finest mechanism of the kind the world has ever seen. It represents about the maximum of power possibilities in aeroplane motors, inasmuch as it develops about two horsepower for each pound of weight. The men who have worked out this extraordinary motor deserve the thanks and heartfelt appreciation of the nation."

Manufacturers Protest.—At a general meeting held in the Kerby House at Brantford of the manufacturers of the Counties of Brant, Elgin, Oxford, Norfolk, Haldimand, Welland, Lincoln and Wentworth, it was decided to send a delegation to Toronto to arrange for a meeting in regard to the order for the curtailment of the gas supply of manufacturers in this district. There was a representative attendance of about forty manufacturers present, many of whom were entirely dependent upon gas to operate their respective plants.

New Equipment.—The Otis Fensom Elevator Co. have purchased a 50 h.p. motor-driven De Laval 3-in. three stage centrifugal pump for use in connection with a hydraulic elevator, which they will install in the Bell Telephone Building. The Hydro-Electric Power Commission of Ontario have purchased six De Laval single and multi-stage pumps for the Ontario Power Company. These range in sizes from 100 to 150 h.p., and all will be motor driven. Sales were made by the Turbine Equipment Co., Ltd., Toronto.

Increased Output.—Efforts are already under way to relieve the coal situation in the Canadian West. In Alberta a large increase is noted in the amount of coal mined and exported. A report just issued states that the total amount of domestic coal mined in 1918 during January, February and March amounted to 810,972 tons, as compared with 744,700 tons mined last year during the same period. In the bituminous field the amounts were 712,313, as compared with 650,319 tons mined last year. Anthracite was 39,409 tons in 1918, as compared with 37,817 last year.

Coal Mixing Plant.—A coal mixing plant is to be installed by the Grand Trunk Pacific Railway at Edson, and contracts for the construction work are now being awarded. The purpose of the works will be to combine three different grades of Alberta coal into a standard fuel, which will be used on all locomotives of the system between Winnipeg and Prince George ,and the consumption of home mined coal will thereby be increased to the extent of 200,000 tons a year. The plant will be in operation about the 1st of August, and employment will be given to some fifty men.

Winnipeg.—One result of the decision to make the West dependent on Alberta for a coal supply this winter has been a move for an investigation into the price that is to be paid. One of the Winnipeg papers has gone into the matter at some length, pointing out that the price of the coal at the mines is from four to four and a half dollars. The same article delivered to the consumer is paid for at the rate of $12.50 per ton, and it is held that the spread is too great. The Winnipeg Board of Control are also taking action in regard to the same matter.

Montreal.—Sir Herbert S. Holt, presiding at the annual meeting of Montreal Light, Heat and Power Company, Consolidated, stated that while the new La Salle gas plant had been considered sufficient for five years' growth, enlargement would be necessary to meet the growing demand. The directors were not inclined to go ahead with extensions just now, because of the high cost of machinery, etc., but an extension in this case was virtually forced on the company by conditions. Sir Herbert referred to the rates for gas and electricity in Montreal being the lowest in America, and reaffirmed the company's intention to make no change unless further increases in cost of operation, taxes, etc., compelled such action.

Patents Issued.—The following is a list of Canadian patents recently issued through the agency of Messrs. Ridout & Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained. H. E. Angold and Wm. Duddell, distance operated mechanisms and signals connected to electric supply systems; Wm. T. Bell, Leonard W. Jones and Wm. H. Watson, motor plow; Wm. J. P. Cloakey, dust collector; Wm. Hooker, atmospheric gas burner; H. and A. Saunders, safety catches for brooches and the like; Henry P. Baird, air moistening and filtering attachment for radiators; Shurly-Dietrich Co., Limited,

POSITION WANTED

SUCCESSFUL SALESMAN, MARRIED, 27 years old, catering to hardware trade east of Toronto to the Sydney's, desires connection with reliable concern. Have A1 connection and thorough knowledge of modern salesmanship. William Baldwin, 752 St. Valier St., Montreal, Que.

STATIONARY ENGINEER, AT PRESENT WITH large power company, desires change. British born, married, ten years' experience in Canada, five years with previous employers. Have had considerable experience in electrical equipment operation and can furnish excellent references. Am looking for a more congenial locality than where now employed. If you need a first-class engineer now or will need one shortly, let me write you further. Box 428, Power House. (p6h)

CHIEF ENGINEER

Wanted by large manufacturing plant in Ontario; must be competent to take charge of Boiler House and several repair gangs; free house, good salary, and permanent position. Address, stating age, past experience, and full details to Vice-President, P.O. Box 360, Montreal, P.Q.

saw blade; G. & J. Weir, Limited, control device for rotary pumps; Gutta Percha & Rubber, Limited, the manufacture of sheet rubber; the Williams, Greene & Rome Co., Limited, reversible cuffs.

CATALOGUES

"The Proper Care of Belts," is the title of a booklet gotten out by the Joseph Dixon Crucible Company. We suggest that engineers obtain a copy for their files. As long as the original condition of life and pliability of a belt is preserved it is worth its cost price. To neglect belts will result in a two-fold loss; a waste of power due to the inefficiency of the belts and increased cost due to frequent belt renewals. Just now as never before it is essential that belting be given careful attention. The booklet contains helpful suggestions for getting maximum results from belts and in addition has several pages devoted to useful information of a general character.

Hydraulic Valves and Fittings.—A new catalogue of hydraulic valves and fittings has just been issued by the Hydraulic Press Mfg. Co., of Mount Gilead, Ohio. The book is quite elaborate in make up and presents the complete H.P.M. line very attractively. The four general classes of hydraulic valves are clearly illustrated and described. These are operating, check, knock-out and safety. Every standard type of hydraulic fitting is also listed, also accumulator controls, pressure gauges, hydraulic pipes, etc. Many of these hydraulic devices are of improved design and are here published for the first time. Interested parties may obtain copies from the above address.

The Collapse of Short Thin Tubes.—Professor A. P. Carman of the Department of Physics, University of Illinois, has completed a series of experiments on the Collapse of Short Thin Tubes. The purpose of these tests was to find an equation by the application of which the pressure required to collapse a tube can be calculated when the dimensions of the tube and the elastic properties of the material are known. The results of tests of longer tubes were published by the Engineering Experiment Station in 1905 and the present report contains a brief summary of these earlier tests. Seamless steel, seamless brass, aluminum, glass, and rubber tubes mere used in the new tests. Bulletin 99 of the Engineering Experiment Station contains the results of these tests. Copies may be obtained gratis by addressing the Engineering Experiment Station, Urbana, Ill.

ALLOYS of from 57 to 63 parts of copper and the balance of zinc are used in the extruding process for making rods, tubes and shapes and a mixture of approximately 50 parts of copper and 50 parts of zinc has the highest content of zinc the alloy may contain and be workable.

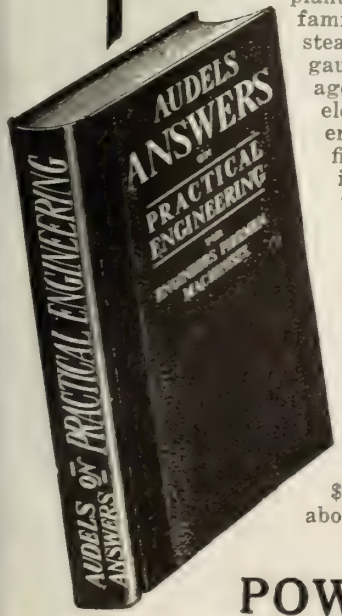
Audel's Answers on *Practical Engineering*



GIVES you the everyday practice and simple laws relating to the care and management of a steam plant. Its 250 pages make you familiar with steam boilers, steam, fuel, heat, steam gauge, installation and management of boilers, pumps, elevators, heating, refrigeration, engineers' and firemen's law, turbines, injectors, valves, steam traps, belts, gears, pulleys, electricity, etc., etc.

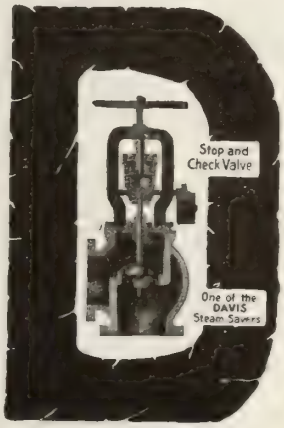
Price, One Dollar.

To subscribers to Power House who send us two new subscriptions, above book will be mailed, postage paid, for 35c. To subscribers who send three new subscriptions, together with $3.00 to pay for same, above book will be sent free.

Address:

POWER HOUSE

153 University Avenue, TORONTO, ONT.



DAVIS SAFETY

protects you and your plant from the possible boiler explosion that may happen next year, next week or *tomorrow.*

Not only does the Davis Stop and Check Valve protect, but it equalizes the load by making each boiler do its share. Automatieally it will prevent a reserve flow of steam caused by sudden drop of pressure; will equalize the loss by cutting out the laggards; and will close tight when the fire is drawn. Reliable, efficient and absolutely dependable. Visible action—will not stick.

For your free copy of the new Davis Catalog, write the G. M. Davis Regulator Co., 434 Milwaukee Ave., Chicago.

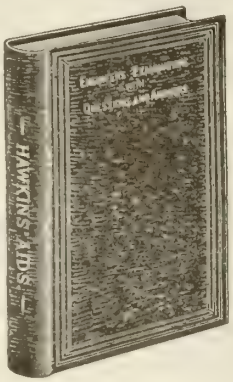
Books for the Engineer's Library

Hawkins' New Catechism of Electricity

It contains 550 pages with 300 illustrations of electrical appliances; it is bound in heavy red leather, with full gold edges and is a most attractive handbook for electricians and engineers. One-third of the book is devoted to the explanation and illustrations of the dynamo, with particular directions relating to its care and management—$2.10 post paid.



Engineers' Examinations

By N. Hawkins, M.E.

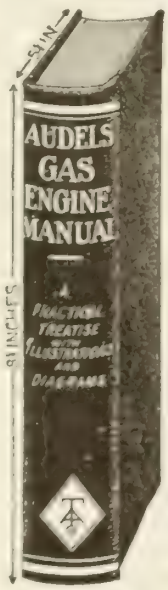
It presents in a condensed form the most approved practice in the care and operation of boilers, engines, pumps, condensers and refrigerating machinery, and covers the work in the problems relating to the safety valve, strength of boilers and horse power of engine and steam boiler.—$2.10 post paid.

Steam Turbines

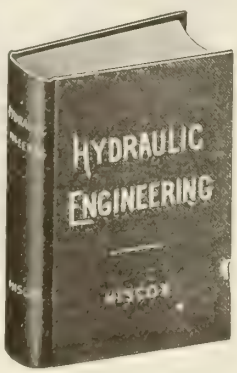
By Leland.

A reference work on the development, advantages and disadvantages of the steam turbine; the design, selection, operation and efficiency of steam turbine plants and turbo-generators. 135 pages. Illustrated.—$1.00.

Audel's Gas Engine Manual



A practical treatise relating to the theory and management of gas, gasoline and oil engines, including chapters on producer gas plants, marine motors and automobile engines.—$2.00.



Hydraulic Engineering

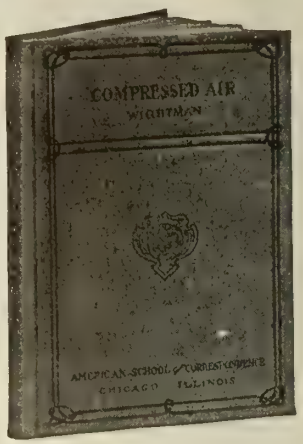
By G. D. Hiscox.

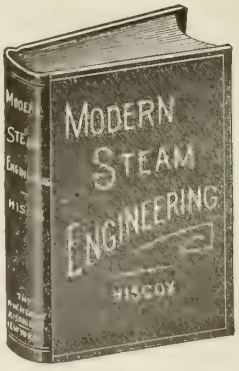
This comprehensive book of Hydraulics written by an experienced engineer, is a practical treatise on the properties, power and resources of water for all purposes, including the measurement of streams, the flow of water in pipes or conduits; the horse-power of falling water; turbine and impact water wheels; wave motors, etc. All who are interested in Water Works Development should have a copy. 320 pages, 305 illustrations. Price $4.15 post paid.

Compressed Air

By L. I. Wightman, E.E.

A reference work on the production, transmission and application of compressed air; the selection, operation and maintenance of compressed air machinery; and the design of air power plants. Illustrated.—$1.10.





Modern Steam Engineering in Theory and Practice

By Hiscox.

This book has been specially prepared for the use of the modern steam engineer, the technical students, and all who desire the latest and most reliable information on steam and steam boilers, the machinery of power, the steam turbine, electric power and lighting plants, etc. 450 pages. 400 detailed engravings.—$3.15 post paid.

Boiler Construction

By Kleinhans.

The only book showing how locomotive boilers are built in modern shops. Shows all types of boilers used; gives details of construction; practical facts, such as line of riveting punches and dies, work done per day, allowance for bending and flanging sheets and other data that means dollars to any railroad man. 421 pages, 324 illustrations, six folding plates.—$3.00.

Compressed Air, Its Production, Uses and Application. *By G. D. Hiscox, M.E.*

Comprising the physical properties of air from a vacuum to its liquid state, its thermodynamics, compression, transmission and uses as a motive power in the operation of stationary and portable machinery, in mining, air tools, air lifts, pumping of water, acids and oils and the numerous applicances in which compressed air is a most convenient and economical transmitter of power.—Price $5.15 post paid.

Boiler Accessories

By Walter S. Leland, S.B.

Assistant Professor of Naval Architecture, Mass. Institute of Technology, American Society Naval Architects and Marine Engineers. 144 pp., 80 illus. Cloth binding. A treatise giving complete descriptions of the various accessories of the boiler room and engine room essential to economical operation, such as evaporators, pumps, feed-water heaters, injectors, mechanical stokers, etc., with practical instruction in their use.—Price $1.10 post paid.

one can be too canny

EXPERIENCE is a thorough teacher, to be sure. But it is unwise to reason that all products advertised to solve the scale problem are inefficient—"no good." Don't let an unfortunate "affair" with a "compound" or "cure-all" keep you from learning about

METLSKIN
BOILER PRESERVATIVE
Neither "Compound" nor "Cure-all"

METLSKIN is a boiler-metal treatment, pure and simple. Not only does it remove old scale, but it also prevents further scale-formation. It preserves boiler-metal, and prolongs the boiler's span of life.

The annual fuel-saving alone will pay for a year's supply, and many times over.

But you need not take our word for this. Send a post card for details of the 60-day trial offer. Let us mail the latest booklet. It will prove interesting reading.

III IMPORTANT THINGS

TO CONSIDER ABOUT A SEPARATOR.

I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

GRATON & KNIGHT

Standardized Series

LEATHER BELTING

Tanned by us for belting use

14-in Graton & Knight Spartan Leather Belting on difficult quarter-turn drive. Standard Box Co., Baton Rouge, La.

Here is Economy

MAKE every ton of coal yield the maximum production." That's the peremptory command of America to manufacturers.

The importance of economical transmission of power cannot be exaggerated.

Economy of transmission is fundamental. It means efficient service. It is the basis of "Standardization" in belting.

Mills that have kept Belt Service records know that the use of Graton & Knight Standardized Series Leather Belts means economy in production. (And to-day they are even more economical, because while they have increased in price, their percentage of increase is **much less** than that of substitutes.)

Talk over the selection of belts with your practical production men, superintendents, and foremen. Ask them these questions: What belts give the longest service? transmit most power? are easiest to repair? have the proper elasticity with firmness? best stand mauling of shifters and flanges? when damaged can be cut down for use on narrower pulleys? when worn out bring the best price for scrap?

If you have kept suitable records, you know how to answer these questions. If not, you are only guessing. Start a belt record immediately. Write us for the necessary cards. An accurate record of belting service is as profitable as a record of a workman's service. Tell us the number of drives in your plant and we will mail record cards gratis.

385

LIEUT.-COLONEL ———, the writer of the following letter, abandoned a lucrative business and joined the Canadian forces in August, 1914. He has never been out of uniform since. He has been in some of the heaviest fighting; has been wounded several times; was given up by the doctors; recovered and is again at the Front; was offered command of a brigade. He is regarded as a man of so much importance that he has been guaranteed a sure seat in the House of Commons and will be one of the chiefs, if not the leader, in the returned soldiers' movements in Canada.

Lt.-Col. John Bayne Maclean,
Toronto, Canada.

France, April 5th, 1918.

Dear Colonel Maclean:-

Yesterday I had handed to me by Captain———a copy of MacLean's Magazine with your article on "WHY WE ARE LOSING THE WAR," which has been sent to him by a lady from Edmonton because of the reference made in it, no doubt, to . . . . . I have read the article over carefully and so have many of my officers and I thought I ought to let you know how deeply impressed we all are with your array of facts and arguments and the manner in which you have marshalled them together in a brief that should bring envy from the best legal minds in Canada.

For a long time I have been filled with the same ideas with reference to the infantile handling of the great affairs of State by the big men of our country and as one who has been brought up in the greatest awe and respect for those high in authority in England I tried to fight against the gradual turn my mind and heart was taking towards these great leaders. Furthermore, being a soldier, I felt it would not be in keeping with my duty to make comment or criticize those in authority and perhaps also I lacked the courage lest I might bring about my ears criticism which must always follow attacks upon big men. I believe there are many others who have shared the same views and for the same reasons refrained from "Talking out in Meetings." You have stepped into the breach and taken upon your own shoulders the burden of a whole people and in doing so I realize what it will mean to you and the courage and fearlessness which you must have in order to have taken this step. I know of no other man who has so boldly set before us Britishers our own case. You will, no doubt, having attacked these great leaders, find yourself in a maelstrom of criticism. You will be called disloyal and you will be vilified and abused, but the truth of your statements cannot be gainsaid and you must eventually stand out as a great and fearless citizen who was not afraid to place himself in jeopardy, that EVEN YET A ROTTEN SITUATION MIGHT BE TURNED INTO VICTORY BY PROPER HANDLING.

The history of this war has been a history of bungling on the part of the higher ups, interwoven with a history of devotion, loyalty and doggedness on the part of men in the ranks, which can never be excelled. It has been one continual panorama of "light brigade" episodes and our brave men still go on fighting knowing that "someone has blundered," yet feeling that blunder or no blunder, we must fight and fight on that civilization may be preserved and British traditions maintained.

Some sections of the public here abuse Northcliffe, Lloyd George and Beaverbrook but having watched things closely for a few months I have come to the conclusion that in these three men and their associates lies the future of the British Empire. The old regime is fighting and dying hard. Incompetency is also tenacious and hangs on doggedly to the high positions where it has been entrenched for so many years in British public life. A few brilliant charges like yours will start such an onrush of public opinion throughout the Empire that sooner or later he will be dislodged, and brains having taken his place, we may look for results. Until that time comes, we need not hope for a change in the present state of affairs.

OUR MEN MUST HANG ON FOR THE TURN OF THE TIDE IN THE BRITISH PUBLIC LIFE FOR AT THE SAME TIME THERE WILL BE THE TURN OF THE TIDE TOWARDS VICTORY IN FRANCE.

Faithfully

Signed.....

The "COLE" Return Trap for Handling Condensation

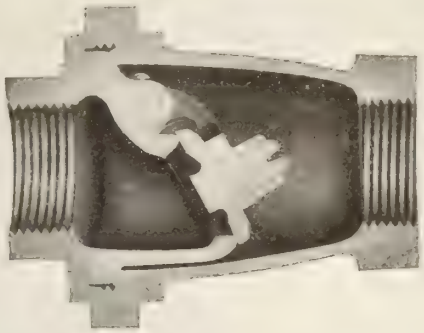
Coal Saved is Money Made

The first steam trap approved by the Steam Boiler Branch of the Department of Public Works of Ontario.

The Cole Trap System returns condensation back to the boiler at such a high temperature that you cannot help but show a saving.

We can cite instances where users have cut their coal bill almost in half. Think of what that means. Others have done it, so can you. Our book, "Steam Condensation," tells how this fuel saving can be accomplished.

You are under no obligation when writing us for advice. Our engineers are at your disposal at any time.



"COLE" Check Valves

Altogether different; there is nothing just like it. It eliminates the troubles that go hand in hand with ordinary check valves.

It's a combination of union and check valve. Made right to hold tight. All brass and fully guaranteed.

Away ahead in everything but price.

DON'T forget to send for our new ***Lightning Calculator.*** It shows steam and fuel losses at a glance. Every engineer should have one.

Geo. W. Cole, Limited

"Can I have another black belt?"

LEATHER TRADE VIM MARK BELT

"Why do you want a black belt?"
"Because I can turn out more work."
"You had one before?"
"Yes, sir."
"What happened to it?"
"One of the night shift stole it."
"How much more work can you turn out with the Black Belt than with the other kind?"
"I was making about $5.00 a day with the old belt. Since I got the Black Belt I've been making $6.50 to $7.00."
"What is the name of the Black Belt?"
"VIM!"
"You get a Black Belt!"

It's 100 per cent. Leather.

The value of, and the advantages of installing,

GREEN'S ECONOMISERS

are not only recognized and made use of in Canada and the United States, but are as well known in every part of the world where steam is generated by stationary boilers.

They are extensively used all over Great Britain and the Continent of Europe, especially in the great industrial centers. South America, Japan and China can also bear witness of their merit as savers of fuel.

The above installation, about 15,000 tubes, is the largest in the world—but whether your plant is large or small our engineers will be glad to submit data showing the saving possible by installing economisers.

Where Electric Power is Made

Municipal lighting companies take no chances when buying equipment. As current must be supplied uninterruptedly, every precaution is taken against shut-downs.

Take corporations such as

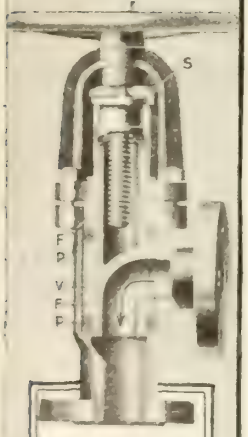
Montreal Light, Heat & Power Co., using 24.
Cleveland Elec. Ill'g. Co., using 178.
Edison Elec. Ill'g. Co., Brooklyn, using 100.
Potomac Elec. Lgt. & Pr. Co., Washington, D.C., using 24.
Duquesne Lgt. Co., Pittsburgh, using 34.
Omaha Elec. Lgt. & Pr. Co., using 97.
Worcester Elec. Lgt. Co., Worcester, Mass., using 36.

Each has its boilers equipped with from 24 to 178 YARWAY (formerly Simplex) "Seatless" Blow-off Valves—a choice that in effect, becomes a recommendation of the very highest character.

In the YARWAY (formerly Simplex) there are no seats or discs to cut, clog or grind down. There are no pockets to gather sediment—no obstructions of any kind. The port is free and wide open. Packing is protected and will last for years.

Other good points may be learned by trying a YARWAY for 60 days. It may be returned if not satisfactory.

Write for one to-day, stating size of line and whether screw or flange, angle or straightway.



Operation:

In closing valve, shoulder "S" on plunger "V" engages the loose follower gland "F," compressing packing "P" above and below the port, making an absolutely tight valve.

NON-CORROSIVE

CYLINDER OIL

MANUFACTURED ONLY BY

E. H. KELLOGG & CO.

NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.

FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done — give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

A Slipping Belt is a Lazy Belt

Lazy belts and lazy men put a drag on production; they are misfits in a well-managed plant. Neither should be tolerated, for their moral effect on efficient operators is bad.

Belt slippage is preventable.

DIXON'S SOLID BELT DRESSING

does the trick and it is absolutely harmless to the belt itself—whether of leather, rubber or fabric.

Ask for a booklet 222-O and free sample.

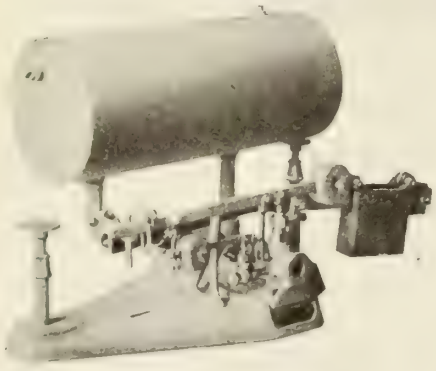
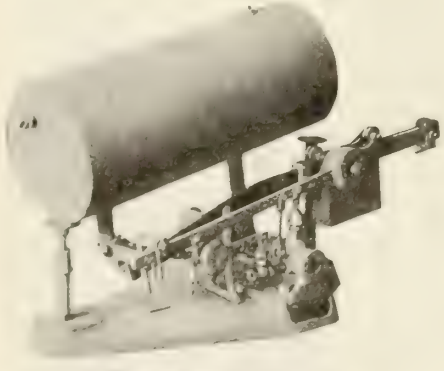
We Must Knock Down Our Fuel Consumption

Manager and Engineer discuss a serious problem.

WILL DO IT



Showing machine in filling position.



Showing machine in discharging position

CONSERVE and SAVE every pound of coal possible. It is imperative. Fuel of all kinds will be higher in price and more difficult to procure.

Is your Steam Plant Equipment 100% Efficient? That is the question you have confronted repeatedly. You will have to confront it again and again. The Morehead Back-to-Boiler System is the satisfactory answer and solution.

The present improved equipment is the result of 28 years' use and experience in thousands of heating and steam plants throughout the world.

THE MOREHEAD is the **original** and has at all times been the standard by which the comparative values of other Steam Traps have been measured.

It is a system of steam coil drainage and boiler feed by which the condensed water is delivered back into the boiler as pure hot feed water without pumps or complex equipment of any kind.

Morehead Machines fill every time and discharge every drop of condensation contained in the tank into the boiler at each operation. This is an advantage not obtained in other machines. As a result the maximum heat unit is thereby conserved.

Morehead capacity is greatly in excess of any filtering return machine in existence.

Send for Booklet, "Morehead Back-to-Boiler System." Read what other users say. Consider the saving this system has effected.

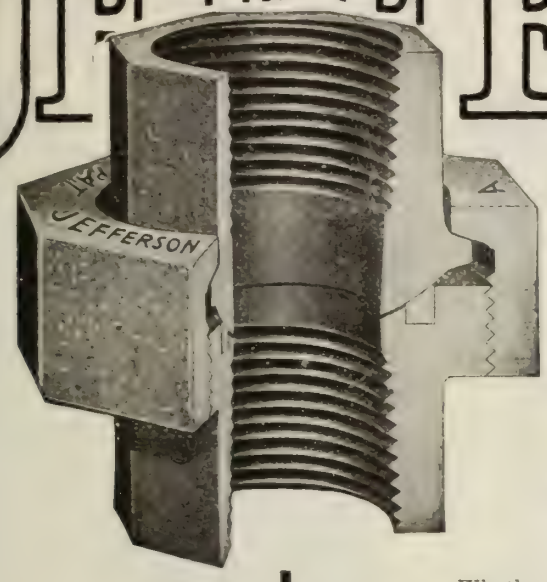
JEFFERSON



Test a Jefferson Union on your Toughest Job

Whether your idea of severe union service is superheat or heavy pressure or corrosive action, you must actually try out a Jefferson before you can realize perfect union service.

Built by specialists, Jefferson Unions embody all qualities necessary for 100% efficiency on pipe line and power plant service. The Jefferson Union is unique in construction because we have protected ourselves with basic patents covering the essential features.

Take the drawn brass seat ring for instance. Now of course, every practical engineer knows that a brass-to-iron joint will not corrode (Point No. 1). But with an all-brass seat the expansion and contraction would be excessive, so in the Jefferson Union we embed the brass seat ring into the malleable iron by exerting enormous pressures—up to 40 tons. The seat ring cannot become dislodged under any conditions. (Point No. 2). Finally the seat ring is ground accurately to fit the spherical face of the other part of the union. This insures a tight joint even though the pipe is slightly out of line. Point No. 3).

And so we could go right along with each Jefferson strong point, but these are all covered in detail in our new Catalog. Send for your copy to-day—we'll tell you where to find the nearest Jefferson Dealer.

JEFFERSON UNION COMPANY
Lexington, Massachusetts

Jefferson Swing Union. Allows connections, ranging from a slight offset up to 90 degrees, and many angle connections.

Union Elbow, all female. Takes the place of a straight union, nipple and an elbow. Also made male and female.

All Male Union. Saves two pipe joints between two female threaded parts.

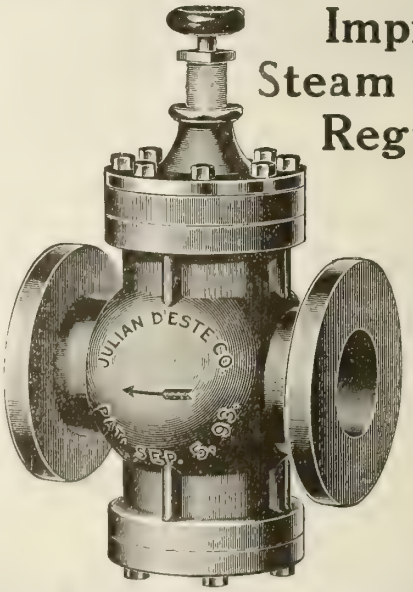
Improved Steam Pressure Regulator



For Universal Application to all the varied and various conditions under which a reduced pressure of steam, water or other fluid is required, this Regulator (see illustration) has no equal. It is compact and self-contained, without levers, weights or projections.

No glands or packing; no drip or leak of steam or water. Suitable for any boiler pressure; made entirely of metal; is a lock valve, very simple and sensitive.

The universality of use of this Regulator is one of its best features, but it is in **Steam Heating** that its use is most common and obvious. Send for leaflet fully descriptive of this Regulator (contains price list) to the manufacturers.

It Ends the Troublesome Drive

Extra power belt on motor generator in Coristine Building, Montreal. Belt is 26 in. x 6 ply, endless. Distance center to center 16 ft. 2 in. Pulleys 24 in. diameter. Speed 4172 F.P.M. Statement of Engineer Hutchinson: "No trouble—a smooth-running belt—steady readings of volt-meter, even with load varying from one to nine elevators—no slippage."

WHEN factory foremen make a point of asking for a specific piece of equipment it must have merits worthy of your consideration at least.

Above is a letter typical of the reputation Extra Power belting is earning in many up-to-date shops throughout Canada.

Particularly in those plants that have a *troublesome, hard, bugbear* of a drive do the super-belt qualities of Extra Power win fast friends.

It is scientifically constructed to ensure those features you expect from a belt—lasting service, economy, flexibility, freedom from trouble.

Its construction guarantees great strength and even balance, without power-squandering weight.

"Extra Power" is flexible—it is long-lasting—it is trouble-proof—free from stretch, shrinkage, ply-separation and pulling loose from the fasteners.

Add to its natural flexibility its gripping surface and you have a belt that hugs the pulleys for the last ounce of power—

—on every drive, light loads or heavy, steady or intermittent.

—but especially on *hard* drives.

Write or telephone the nearest Goodyear Branch. No obligation is involved in getting the trained and expert advice of Goodyear belting men.

EXTRA POWER BELTING

"CLING-SURFACE! Why I heard of that twenty years ago! Never took much stock in it, George"
"Well, Uncle, I couldn't get along without it"

Back in '96 and '97, when "Uncle" ran an engine, people took more for granted.

For instance: power lost between engine and machines. With shafting true and bearings oiled, they still lost a lot of power because the belts slipped.

Their belts were run tight. When stretched they were taken up again. This caused friction, which ate up coal and kept the shop busy filling oil cups and cooling hot bearings. So between slipping belts and this friction, 5 to 30 per cent. of the power was lost.

Yet no belt, unaided, could run under full load **without** slipping. If the belts were heavy enough, and the pulleys large enough, a good deal of slip was avoided, but larger equipment required more power to move it.

And sticky belt dressings were as harmful then as to-day. They stopped belt slip for a time, but gummed up both belt and pulley faces; they tore the belts and, often containing rosin or other injurious materials, eventually destroyed them.

It was about this time CLING-SURFACE was discovered. A small beginning: its name did not stare at you in the [illegible]

Yet CLING-SURFACE soon became well known. People heard of it because it accomplished things.

For tension was doing by **main force** what could better be done by **"persuasion."** And the men behind CLING-SURFACE had found this better way.

CLING-SURFACE stopped the slipping. Since this was [illegible] power cause for tension, with slipping already stopped, why use it at all?

The Cling-Surface Company preached **slack** belts. Manufacturers who tried CLING-SURFACE discovered a great [illegible] No take-up was necessary, there was no slipping, belts lasted longer, and more power was delivered to the machines with less oil, coal, time and money required than when the belts were run tight.

CLING-SURFACE has grown for twenty years because it has kept on accomplishing things. And it will do the same for you.

We have many interesting booklets; one may describe your conditions. Let us send it to you—with the plan 10,000 firms have found successful. All free.

Remember, use CLING-SURFACE and you won't need belt [illegible]

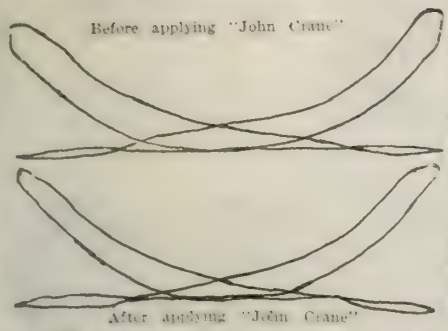
Before and After Applying "John Crane" Metallic Packing

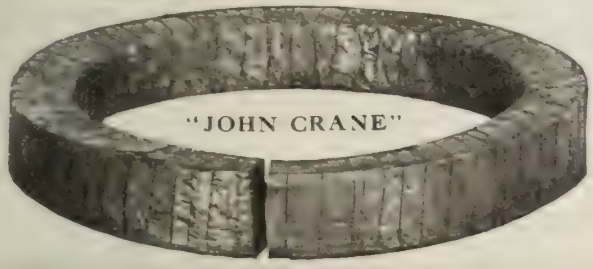


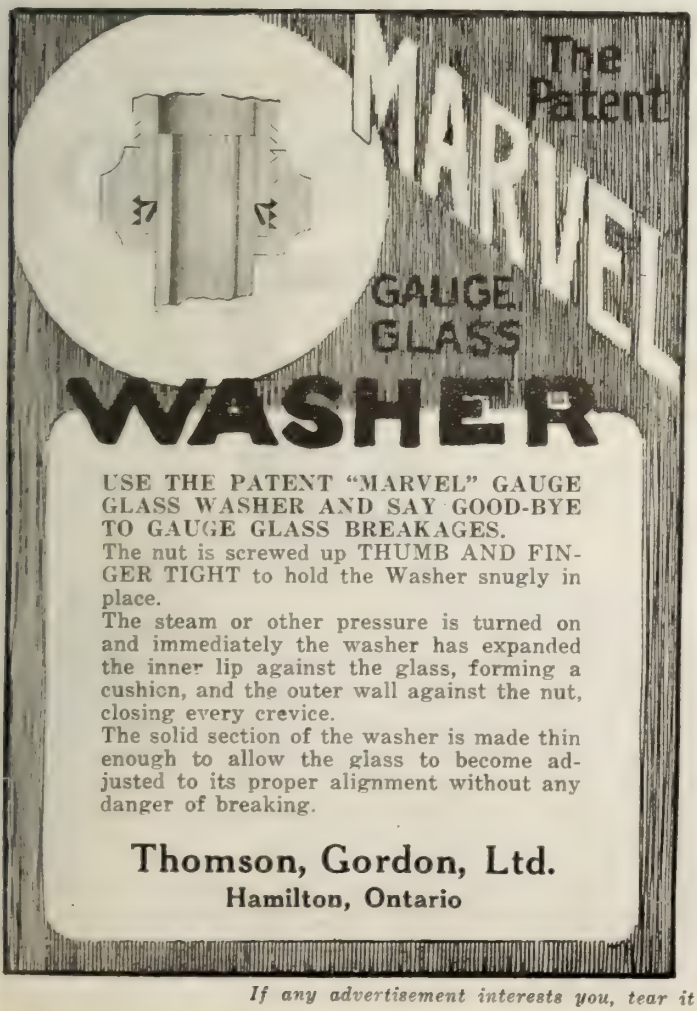
The best way to prove to your own satisfaction that John Crane Flexible Metallic Packing saves power is to take indicator diagrams before and after "John Crane" has been put in place. The diagrams at the left are typical friction cards. The power saving due to "John Crane" is directly proportional to the reduction in area of the cards.

Power saving is important, of course, but the above diagram represents only one of the many reasons why "John Crane" is preferable to all other makes. It is not at all like the shredded, twisted, braided, granulated, shot, metal and other types of so-called flexible metallic packing and is far superior to fibre packing for numerous reasons that cannot be told in this small space. A knife cuts it just like fabric. Made of smooth, sheet copper foil with high grade lubricant and graphite wrapped between every layer. Any engineer can get this packing on approval provided his rods are new or good. Bulletin No. 1 tells about it.

Crane Packing Company **Box 241, Windsor, Ont.**

General Office and Factory, Chicago, Ill.





USE THE PATENT "MARVEL" GAUGE GLASS WASHER AND SAY GOOD-BYE TO GAUGE GLASS BREAKAGES.

The nut is screwed up THUMB AND FINGER TIGHT to hold the Washer snugly in place.

The steam or other pressure is turned on and immediately the washer has expanded the inner lip against the glass, forming a cushion, and the outer wall against the nut, closing every crevice.

The solid section of the washer is made thin enough to allow the glass to become adjusted to its proper alignment without any danger of breaking.

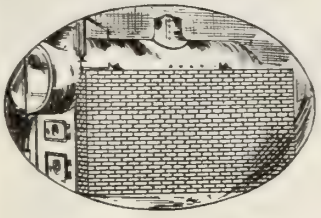
FIRE-BRICK WORK

in all its Branches

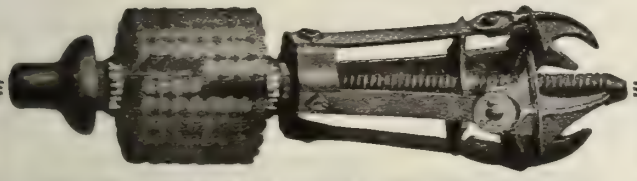


Your boilers need protection. Let me brick them up for you; this is my specialty. First-class, durable work—moderate cost.

Write for prices and particulars.

J. H. Wenting, Toronto, Ont.

Mason Contractor Phone Beach 1353 256 Lee Ave.



Looks like a good tool and it's just a little better than it looks. Adopted as standard by thousands of engineers who know from experience that it always gets results.

Pilleys Combination Flue Brush and Scraper

is adjustable to the tube—scraps and brushes thoroughly in one operation. Guaranteed against defective materials and that wires will not pull out or lay over. For sale by leading Canadian jobbers.

Eastern Office: 71 Fulton St., New York.

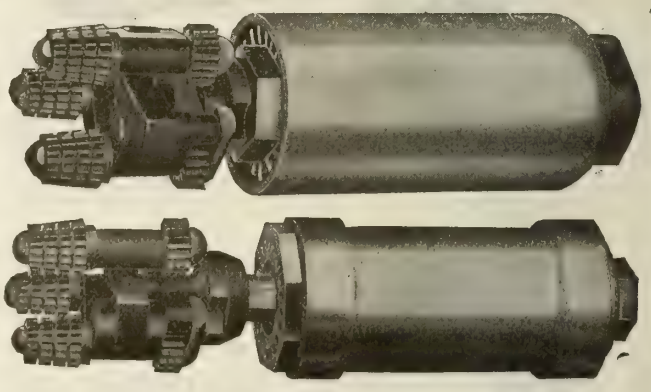
BABCOCK & WILCOX LIMITED

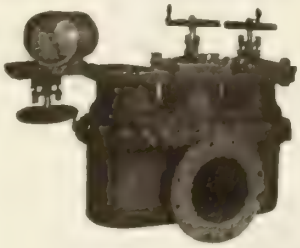
LAGONDA
BOILER TUBE CLEANERS

The latest Lagonda Water and Air-Driven Boiler Tube Cleaners are the most powerful and efficient tube cleaners made. They develop higher speed and greater power than has heretofore been secured with any Turbine Cleaner, and their use will materially shorten the time required in cleaning boilers.

These new Lagonda Cleaners are built for all sizes of tubes, either straight or curved, and they can be driven by water, air or steam.

Ask for Catalog L.





LAGONDA Multiple Water Strainers

The Lagonda Multiple Water Strainer in your water supply main will remove all objectionable solid matter and insure constant and economic conditions of pump and condenser operation. They are easily and quickly cleaned, without interruption of water supply, and take up small floor space. **Ask for Catalog R-2.**

POWER HOUSE BUYERS' DIRECTORY

If what you want is not listed here write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers names under proper headings is gladly undertaken, but does not become part of an advertising contract.

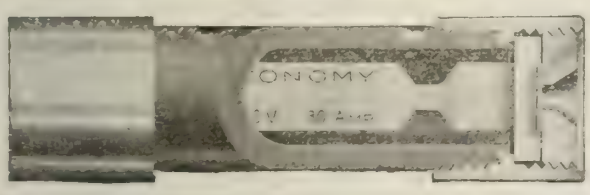
Manufacturers in Canada of S & B High Potential Fuses to 150,000 Volts.



LANCO BALATA BELTING

is now one of the most expensive belts on the market.

When the cost of raw materials increased the price of this belt to where it is to-day, we were a little afraid that it would result in a diminution of our sales. We have been very agreeably disappointed—the sales have not dropped off.

There are cheaper belts on the market that will give as good service but not for so long. That is the secret of the steady demand for Lanco Balata Belting. The method by which this belt is made ensures a very strong and long-lived material. The duck is very heavy and is so tightly woven that the only method of using a gum that would hold the plies tightly together is by impregnating the duck with a solution of gum. This method is used in making Lanco Balata Belting, and when the solvent evaporates it leaves the gum dry, pliable, and with a strength that, as far as we know, has never been equalled by any other gum. The duck is, of course, stretched while in the solution and until the solvent has evaporated. Balata gum softens at a temperature of 120° F., but under any atmospheric conditions, except those of heat, it will give a length of service that makes its price worth while.

Fearless and Entertaining

This is the most momentous time in history, and you want your reading to keep you abreast of what is happening in the world. You want articles that are timely, vital, fearless. Here's what is offered in June MACLEAN'S:

Must the British Empire Cease to Exist? Must all nations, as separate nations, cease to exist? Read what is said on this subject by - - - - - - - - - - **H. G. Wells**

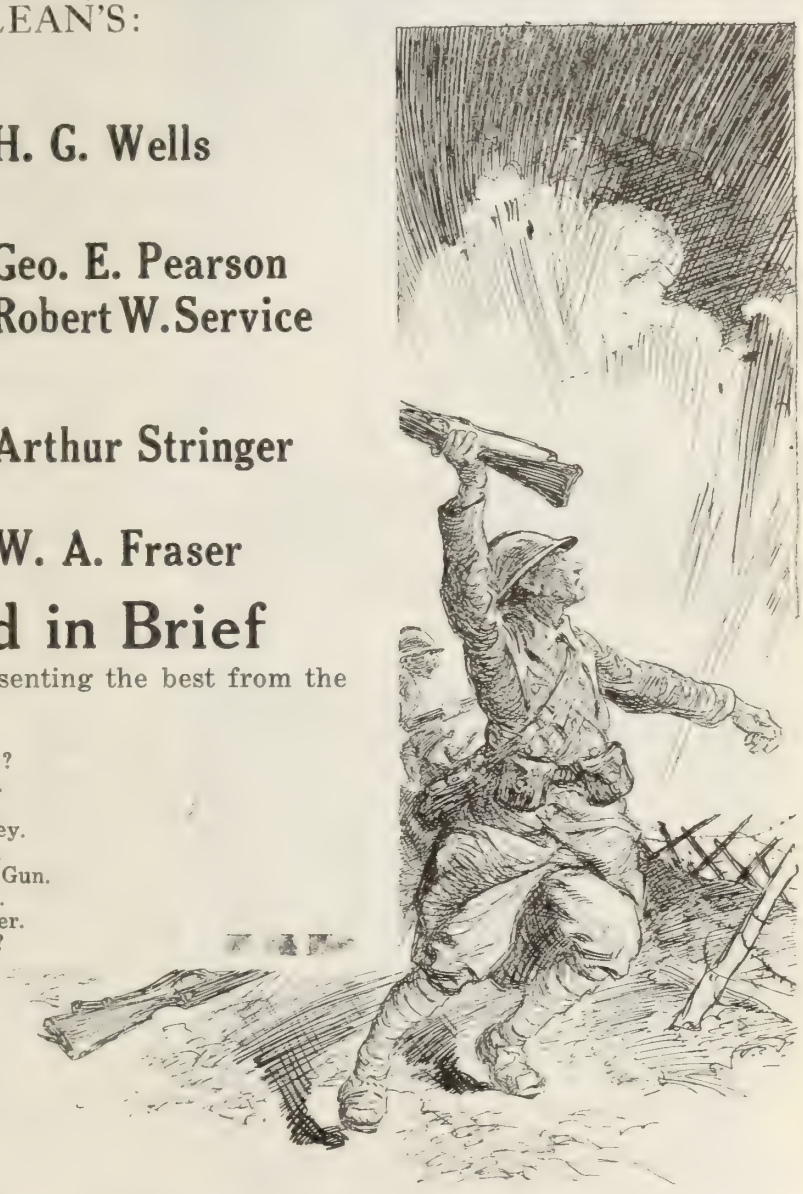
When a thousand guns play on a single trench, what happens in that trench? A powerful description by one who lived through it by - - - - - - - - - **Geo. E. Pearson**

A soul-stirring ballad of the trenches by **Robert W. Service**

Galvanizing the Government at Ottawa. An article on the work of the Ginger Group.

A gripping mystery story by - - - **Arthur Stringer**

The Three Sapphires—A new serial story combining Hindu mystery and war intrigue by a great Canadian novelist. **W. A. Fraser**



News of the World in Brief

The following articles are reprinted as representing the best from the best magazines the world over:

Is This Germany's Plan?
Is Japan Seeking a New Ally?
How Allied Victory Was Lost.
Is Foch Another Napoleon?
How Germany Annexed Turkey.
The Death of General Maude.
That Mysterious Long Range Gun.
How Bolo Pasha Was Caught.
The World is Growing Warmer.
Super-Kaiser or Little Willie?

Wanted—

Engineers to Contribute to Power House

THIS is a practical paper for practical engineers. It is an educational medium and out to help its readers. It is a technical school and a social meeting place combined. It is first, last and all the time an engineer's paper.

If you should meet two or three or a dozen of your brother engineers you would swap ideas—you'd tell of some idea you had worked out in your plant. Others would describe some pet schemes they had devised. And so you would be mutually benefited.

Why not make Power House your monthly meeting place? Why not describe in this paper some kink or scheme you have worked out and found successful? We will pay you for it and you, in turn, will be multiplying the usefulness of your idea five thousand fold!

Never mind polishing up your letters—just give us the idea; that's the main thing. Never mind how crude your pencil sketch may be. We have draughtsmen who will finish up your drawings so they may be reproduced.

Try this idea a time or two and see how much satisfaction you'll get out of it. Start the ball a-rolling and thus help other engineers, yourself and your paper.

POWER HOUSE, 143-153 University Avenue, Toronto, Ont.

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an immense saving in cost. For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CATALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.**

MACGOVERN & COMPANY, Inc.

114 Liberty St., New York City

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID, Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D., Supt. Trades & Labour Branch

D. M. MEDCALF,
Chief Inspector of Steam Boilers.

Add 10 Feet to the Length of Your Arm

There are two ways to close an overhead valve—either carry a ladder to it—or else give a slight pull on the operating chain of a

Babbitt
—Adjustable—
SPROCKET RIM

The Babbitt Rim is attached to the valve wheel by three hook bolts. It takes only 5 minutes and a wrench to do the job.

Why not try one? Or send for Descriptive Pamphlet.

Illustration shows an Inglis Horizontal Cross Compound Heavy Duty Corliss Engine recently installed in the new plant of the Canadian Kodak Company Mount Dennis (near Toronto), Ont.

Cylinders are 18 in. and 30 in. by 30 in. stroke, running at 150 r.p.m. Direct connected to a 300 k.w. Canadian Westinghouse 3-wire, 125-250 volt, d.c. compound wound computing pole type generator.

Engine operates on a steam pressure of 150 pounds, with 5 pounds back pressure. Valve Gear is operated by double wrist plates set for long range cut-off, the governor controlling both high and low pressure cylinders. Flywheel is 11 ft. in diameter and weighs 22,000 pounds.

CANADA'S MOST PROMINENT INDUSTRIAL CONCERNS HAVE SHOWN A PREFERENCE FOR INGLIS ENGINES.

Put your Engine problems in our hands—tell us of your special requirements and Inglis Experts will go into details immediately with you, without charge, and without placing you under any obligation to us whatever.

Stocked by Leading Jobbers.

Penberthy Injector Company, Limited, Windsor, Ont.

Unequaled Service Through Co-operative Distribution

One of the principal objects accomplished by the new method of marketing our mechanical goods is the increased co-operation that has been made possible with dealers and jobbers.

The well-known brands of our subsidiary companies—

Revere Rubber Co.
Peerless Rubber Mfg. Co.
Mechanical Rubber Co., Cleveland.
Mechanical Rubber Co., Chicago.
Sawyer Belting Co.
India Rubber Co.
Eureka Fire Hose Mfg. Co.

are now marketed through ONE strong sales organization—
UNITED STATES RUBBER COMPANY, MECHANICAL GOODS DIVISION

We are now able to offer dealers and jobbers a stronger and more complete line of mechanical goods than ever before offered by any rubber company.

We deeply appreciate the great service rendered by dealers and jobbers to consumers. We feel that in making it possible for consumers to purchase their favorite brands of packing, belting and hose through their own dealer and jobber, we are assisting the consumer as well as the dealer and jobber. Dealers and jobbers everywhere now have an unexampled opportunity to promote the interests of their customers as well as themselves, by taking advantage of the attractive proposition presented in the wide variety of well-known brands assembled in the United States line of mechanical rubber goods. We wish and intend to do everything to extend the numbers of dealers and jobbers, as we realize that this means greater service to consumers.

Dealers and jobbers are enthusiastically co-operating in the new plan, and as merchants they have been quick to grasp the strength of this complete line of mechanical rubber goods, embracing such famous brands as

Rainbow Packing
Honest John Packing
Peerless Spiral Packing
Rainbow Belting
Eureka Fire Hose
Giant Steam Hose
Relio Conveyor Belt
Holdtite Friction Tape
Rainbesto Packing
Buckeye Splicing Tape
Four-Ace Seamless Belting
Paragon Fire Hose
Anaconda Tender Hose
Peerless Air Hose
Kold-Pak Jar Rubbers
Revere Garden Hose
Spring Step Heels
Giant Seamless Belting
Giant Suction Hose
Usudurian Packing

all bearing, in addition to their own well-known trade-mark, the great seal signifying service and quality of the largest rubber manufacturer in the world.

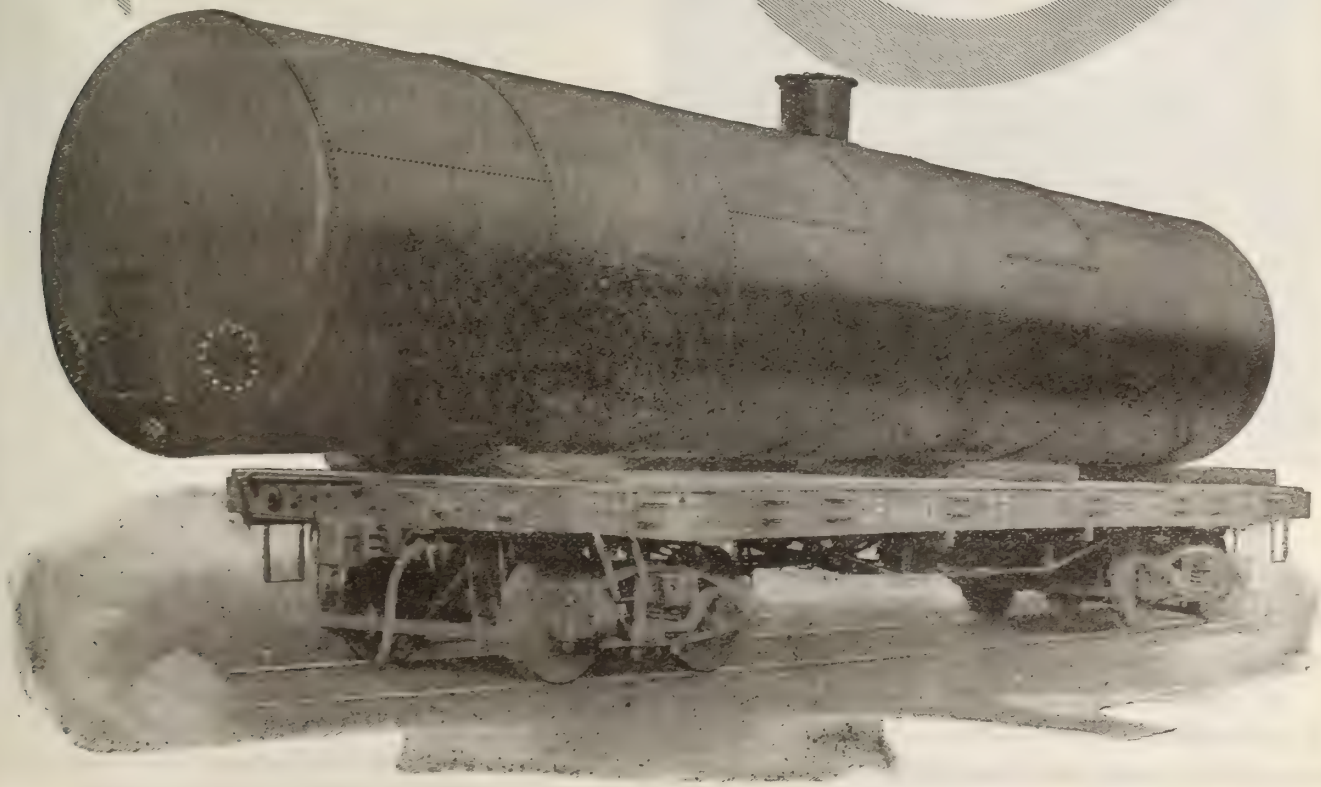
BRANTFORD - CANADA



Be Fair to Your Engineer—and *Good* to the Bearings in Your Plant

Supply HOYT METALS

For Hoyt Metals will make the work of your engineer easier, because bearings properly babbitted with Hoyt Metals will not need re-babbitting nearly as soon as bearings babbitted with common alloys. That is readily understood if you consider that more than a theoretically correct formula is essential to the making of a perfect babbitt. There must be long experience in the actual mixing of alloys and a very intimate knowledge of the various services required of a Babbitt.

Hoyt Metal Company

Eastern Avenue and Lewis Street
Toronto, Canada

London, Eng., New York, U.S.A.
St. Louis, Mo., U.S.A.

FROST KING

Hoyt's famous general purpose babbitting metal has been introduced into the most particular power plants in the world, and is there to stay. Represents the accumulated experience of 40 years. A trial will prove its value in your plant.

NICKEL GENUINE

Is designed especially for use in gas engines, gasoline engines, and all classes of marine engines, and is especially adapted for automobiles. For heavy duty, high speed work, is probably as perfect as an alloy can be made.

Boiler Scale Costs More than Boico

Think of all you pay for it—Boiler scale. In the course of a year you pay tons of coal, and all the time it acts as a check to power efficiency. Like corroding rust, it slowly but nevertheless surely shortens the life of your boiler.

The cost of Boico is trivial compared with all you pay for scale. For Boico positively removes boiler scale and absolutely prevents further formation. It saves fuel, oil and packing. It will not carry over in the steam; it will not cause foaming or priming, and it is guaranteed not to injure packing or valves in the slightest. **Write for free trial.**

Anti-Clinker Shell Bar Grates

insure more heat from much less coal. Built on a scientific air-draft principle, fully 50% of the total surface air space, they provide ample air to command perfect combustion, adding as much as 25% more heat to the fuel gases and so preventing clinker formation. Moreover, Anti-Clinker Shell Bar Grates cannot twist or warp, and they're easily cleaned.

Copper Asbestos Boiler Gaskets

are made of copper, with pure asbestos cord-filled corrugations. They put a stop to leaks in pipe lines, for they never blow-out and never stick.

Tip-It Patent Welding Process

gives you tools whose shanks are carbon and whose cutting tips are high-speed steel. A money-saver!

Get in touch with us to-day!

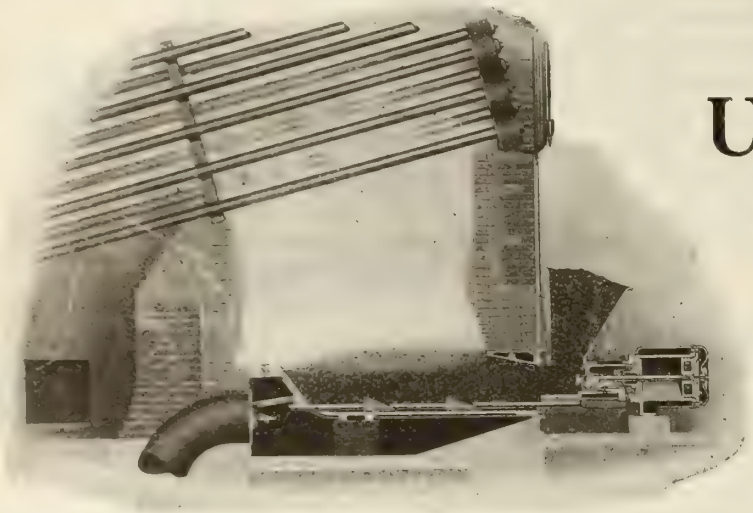
Shell-Bar Boico Supply, Limited

376 Dufferin St., Toronto, Canada

Gives You a Fuel Saving of 15 to 25% and a Smokeless Stack

It gives you a steady steam pressure regardless of fluctuating loads, and scientifically gets all the energy out of coal by perfect automatic control of fuel and draught.

The Jones Underfeed Automatic Stoker hasn't a working part that moves in contact with the fire. It is the simplest stoker built—no grates to lose fuel through—no complicated mechanism.



JONES UNDERFEED STOKER

is the fuel saver needed in your plant. **Let us put you in touch with a number of users.**

Jones Underfeed Stoker
Company, Limited
37-41 Britain St. - TORONTO

Cyclone SHAKING and DUMPING Grates

Should be under your boilers, because Cyclone Grates get the most out of screenings, hard coal or soft coal of cheapest grades.

No Clinkers and No Waste as a Result of 60% Air Space and 90% Underdraught.

Let us fully explain the jarring, shaking movement of Cyclone Grates, which cleans the ashes off the centre of the bars without letting good fuel drop into the ash pit.

Problem for Canadian Power Plants!

Present indications are that fuel shortage will constitute an exceedingly serious problem for Canadian power plants throughout the duration of the war.

You owe it to your country and you owe it to your own business interests to give this problem your most serious attention. And the time to take action is NOW.

Back up the Fuel Controller in his efforts to ward off a crisis and at the same time save money for yourself by installing

COPPUS Turbo Blowers

Fill the Bill in an Emergency

Overseas shipping and railroads demand the best grade of bituminous coal. They must be supplied equal to their requirements. You may have to burn a low grade of coal as a consequence. But this will not cause you any concern if you have installed **Coppus Turbo Blowers.** They enable power plants to make steam with anything in the form of coal—even what looks like black dirt—and at the same time greatly increase boiler capacity. Because they make combustion conditions instantly adjustable to the coal, no matter what the grade—because the draft is always under CONSTANT CONTROL. Scientifically correct design; simplicity, ruggedness, power and low steam consumption make COPPUS TURBO BLOWERS constant dividend payers under normal conditions as well as indispensable in emergencies. **Write us and let us show you how easily you can cope with the fuel problem which is bound to confront you for one, two or three years to come. The fact that we are equipping on an average 100,000 B.H.P. per month with Coppus Turbo Blowers is ample proof of our ability to serve you.**

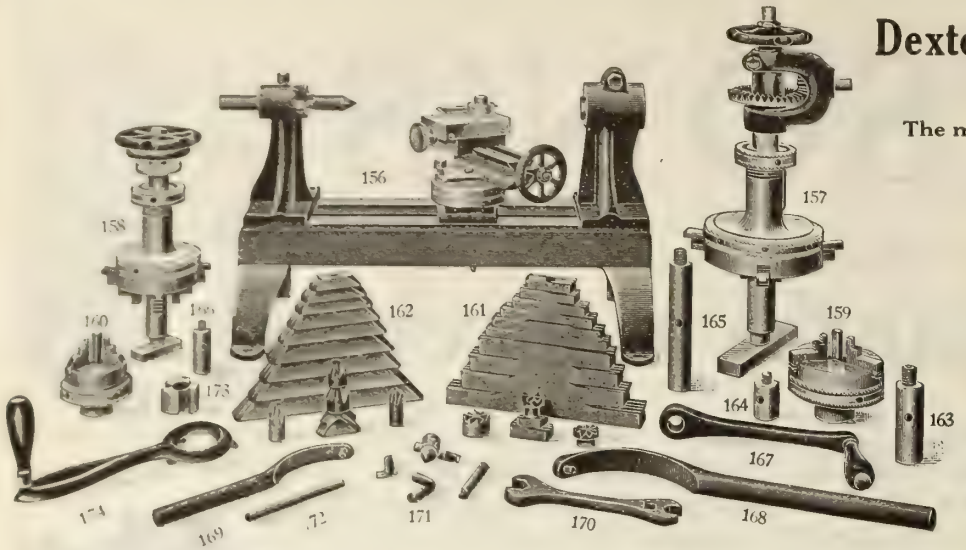
New Bundy Return Trap



Dexter Valve Reseating Machine

The much admired machine at the C. A. S. E. Convention

BY request, we are in this issue showing the Dexter Valve Reseating Outfit.

This outfit is complete for reseating all flat and taper seated globe valves from ¼" to 6" inclusive.

It includes two complete improved Globe Valve Reseating Machines. It has fifteen steel cutters for flat and fifteen steel cutters for taper seats, one improved turret disc, including those having radial wings or projections, check valves, etc., one disc holding chuck, extension spindles, and set of recess cutters, spanners, etc., as shown in illustration herewith; all neatly packed in a polished case with tray for cutters.

The great feature with these machines is that with proper care, they will last a life-time, and pay for themselves over and over again.

The price of valves to-day is about three times as much as three years ago. Use a valve reseating machine instead of buying new valves.

The refacing of a flat seated globe valve ten or twelve times reduces the seat to the level of the body of the valve. A new seat can be raised by using this little recess attachment shown in illustration, and the life of the valve extended. This attachment is worth its weight in gold to the user of a Dexter machine.

Eight Years of Trench Service

No, this isn't "Somewhere in France." It is a pipe trench "Somewhere in Lincoln, Nebraska," and runs from the main plant of the Lincoln Hotel to the Annex.

This Nonpareil Cork Covering was installed in 1907 and for eight years the brine was never shut off. Constantly subjected to moisture and with a steam pipe close by, the Nonpareil Cork saved ton upon ton of refrigeration year after year with no appreciable loss of efficiency.

While its installation underground in this fashion is not generally recommended

Nonpareil Cork Covering

For Cold Pipes and Tanks

is built for hard service and will last for years, if properly applied. It is made solely of clean granulated cork, one of the best nonconductors of heat known. Furthermore, it does not take up moisture by capillary attraction. Where other coverings become water-logged and worthless, Nonpareil Cork will keep on rendering effective service indefinitely.

Armstrong Cork & Insulation Co. Ltd.

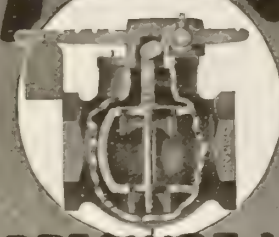
DAVIS



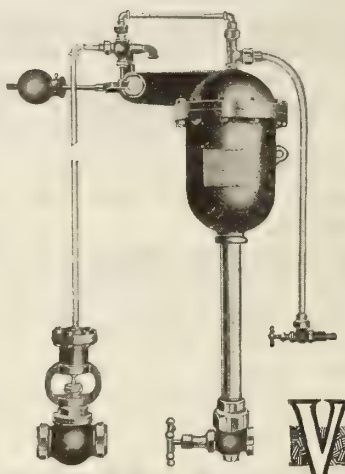
BACK PRESSURE VALVES

are designed to maintain a constant back pressure of steam for heating, drying, cooking or other purposes where light pressure is needed. On the exhaust line of a non-condensing engine, the Davis Back Pressure Valve fills the need. For use with condensing engines or turbines the Combination Back Pressure and Exhaust Relief Valve maintains the back pressure when running non-condensing and acts as an exhaust relief when operating condensing. Noiseless and absolutely reliable — cannot stick or bind.

These consistent steam savers are all illustrated and fully explained in the new Davis Engineering Booklet. For your free copy address the G. M. Davis Regulator Co., 434 Milwaukee Av., Chicago. Branches in principal cities.

DAVIS VALVE SPECIALTIES

STEAM SAVERS SINCE 1875



Keeps the Water Within ¼" of Middle Gauge

This VIGILANT

Automatic Feed-Water Regulator

It does precisely **that,** automatically, perfectly, regardless of the load or firing. Therefore it is a positive protection from all high and low water accidents.

Incidentally—and this we can also prove—the Vigilant Feed-water Regulator saves 3 to 17 per cent. on fuel costs.

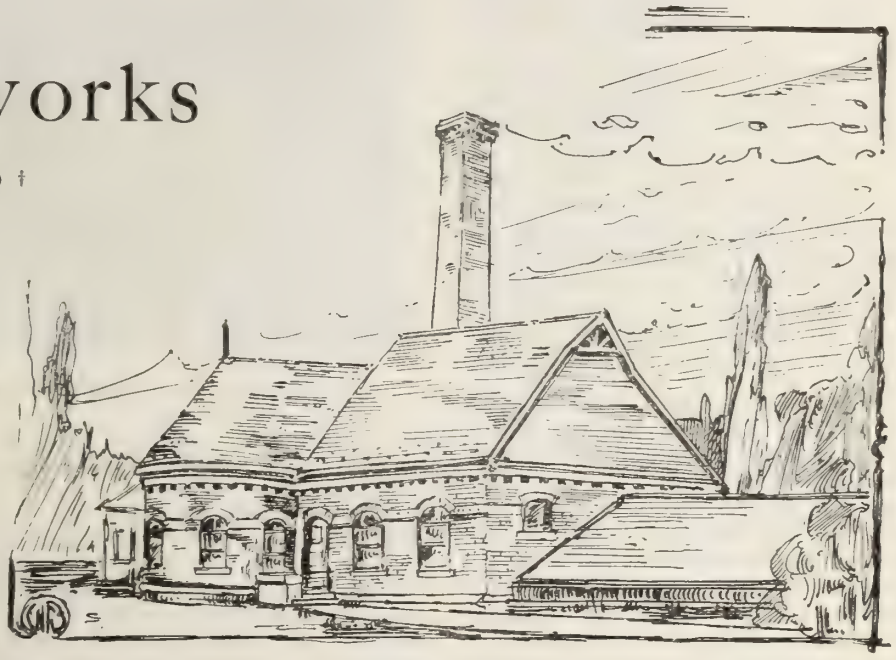
POWER HOUSE

Galt Waterworks

By W. F. SUTHERLAND *

Combined steam and hydro-electric pumping station. Spring water of exceptional purity taken from limestone formation used.



THE City of Galt is fortunate in its water supply, having at all times an ample supply of cool and exceedingly pure water of excellent quality. The pumping station, while located on the Grand River a short distance south of the city, draws its supply from springs and wells driven through the underlying limestone formation. This results in the obtaining of a water which, though somewhat hard, is practically free from bacteria and organic contamination and which requires no treatment with chlorine or filters before being used.

*Associate Editor Power House.

Water Supply

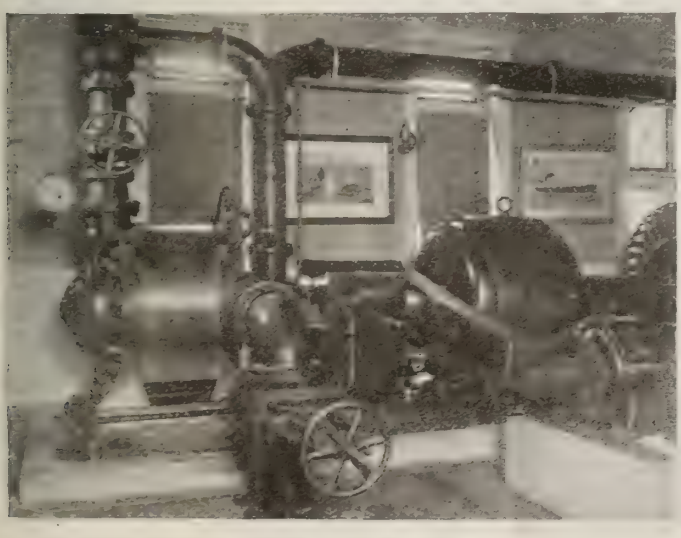
The water from the springs, of which there are a number on the seventeen acres forming the waterworks property, is gathered in a collecting gallery and flows by gravity into a pump-well or basin, forming part of the pump house.

This pump well is about 25 ft. wide and 100 ft. long with concrete walls and bottom, and when full contains about 218,000 gallons of water, thus forming a storage reservoir and an admirable source of supply from which to draw in case of fire or other suden need.

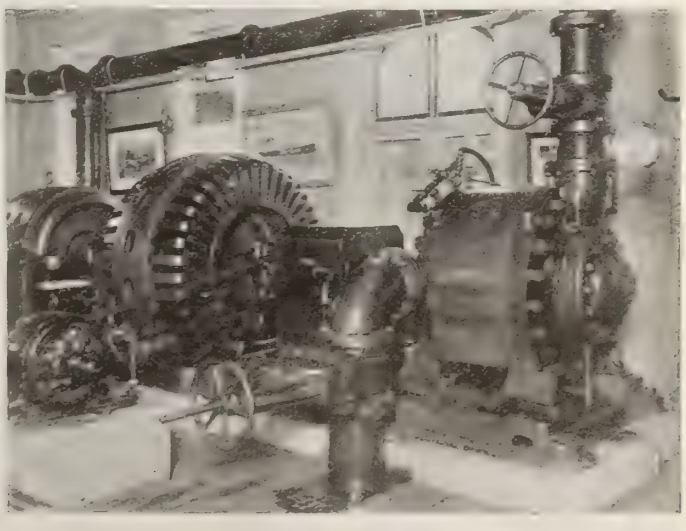
Four wells have been driven to depths ranging from 240 ft. to 252 ft. in depth. Three of these, of 8in. bore for the first 40 ft. and 6in. thereafter, are located outside the pump-house, while the fourth is located under the pump well. This last well is 12ins. for the first 40 ft. and 10ins. for the remaining depth.

Plant

The pump-house is a substantial brick



CANADA FOUNDRY TURBINE PUMP DIRECT CONNECTED TO SWEDISH GENERAL ELECTRIC SYNCHRONOUS MOTOR.



CANADA FOUNDRY TURBINE PUMP DIRECT CONNECTED TO WESTINGHOUSE SYNCHRONOUS MOTOR.

structure built in 1891 when the waterworks was first developed and houses not only the original equipment but the electrical installation since added.

The original equipment consisted of two 72 in. by 16 ft. horizontal tubular boilers, supplying steam to a Jerome Wheelock engine pumping unit. This engine although 27 years old is in excellent condition and beyond the adjustments necessitated by wear has never required a complete overhauling, the cylinders and valves being in perfect condition.

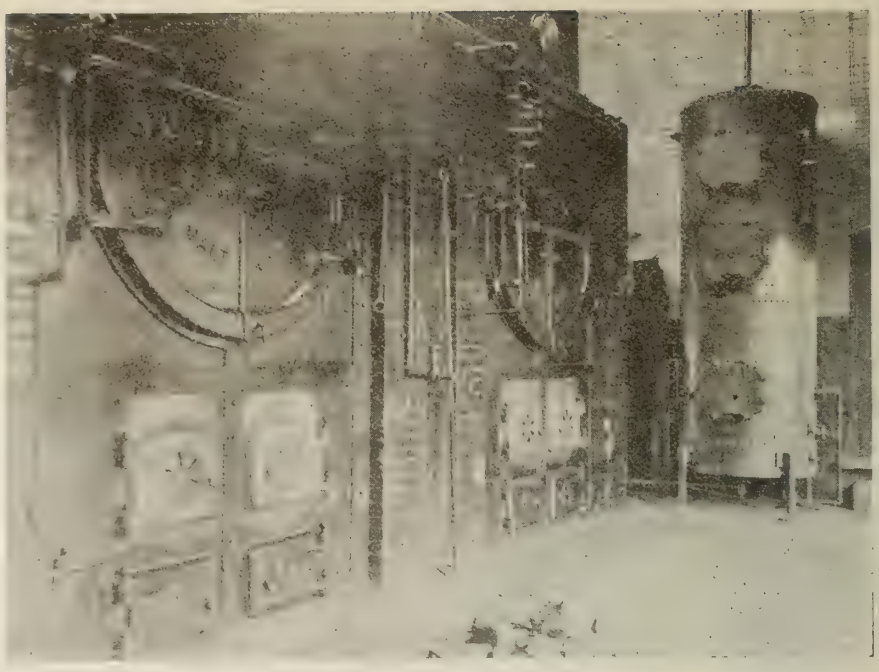
As will be seen from the illustration the engine is cross-compound condensing with the pumping cylinders connected tandem behind the steam cylinders. A jet condenser forms part of the equipment and the air pump is worked from a rocking arm attached to one of the piston rods. The steam cylinder sizes are 13 x 26 ins. by 30 ins., stroke and the pump plungers are 7½ ins. diameter. When running at 50 revs. per min. this unit has a 24 hour duty of 1,500,000 gallons.

Banked fires are carried at all times, the Wheelock engine forming a valuable reserve feature supplementing the electric pumps.

Several years after the original installation was completed it was decided to purchase an additional pump as an auxiliary feature and accordingly a Northey duplex compound pump was added. This dump also shown in one of the illustrations has a capacity of 1,000,000 gallons per 24 hours when running 65 strokes per minute.

Boiler Room

As mentioned above banked fires are carried under the boilers at all times as a precaution in the event of power failure. The boiler room contains two 72 in. by 16 ft. horizontal return tubular boilers installed six years ago by the Goldie & McCulloch Co. A pressure of 120 lbs. is maintained when the steam plant is in operation. An open type Moffat feed water heater and the necessary boiler feed pumps are also installed in the boiler house.



VIEW OF BOILER ROOM SHOWING MOFFATT FEED WATER HEATER.

Turbine Pumps

Several years ago it was found that the capacity of the steam equipment was insufficient to meet the needs of the rapidly growing city, and various methods were considered for increasing the capacity. About this time hydro power was made available, and it was finally decided to instal turbine pumps driven by a synchronous motor.

By the use of a synchronous motor-driven unit power factor correction could be applied to the local hydro system and a considerable economy effected.

The unit as originally installed consisted of two Canada Foundry turbine pumps of 800 gallons per minute capacity delivering water at 11 lbs. pressure and having three stages. These pumps were designed for 270 ft. discharge head when working with a suction lift of 15 ft. The suction inlet of each pump is 10 in., while the discharge is 8 in.

The suction piping of the pumps is so arranged that they may either draw from the wells alone, the tank, or from both wells and tank.

At present one pump draws water from the three outside wells while the other one draws from the well in the pump house, the water also being pumped out of the reservoir when the springs have nearly filled it.

The pumps may be primed either by straight city pressure from the mains or by means of a water injector worked also by city pressure.

Original Pump Layout

As originally installed the two pumps were mounted on the one bedplate with the motor between. Clutches were provided so that either pump could be disconnected for repairs or because of light water requirements. Owing, however, to difficulties in operation and the desire for increased motor capacity for power factor correction this arrangement has since been altered by the addition of another motor, making two separate units.

Dodge couplings are fitted between each motor and its pumps so that the motors may be run solely for power factor correction if desired.

JEROME WHEELOCK PUMPING ENGINE. THIS ENGINE HAS BEEN IN CONSTANT SERVICE SINCE 1891.

Electrical Installation

The original motor installed with the pumps was supplied by the Swedish General Electric Co. This machine is a 2,200 volt 25 cycle motor running at 750 revs. per min. and is rated at 66 amperes full load. It is furnished with a 6.6 kw. belt-driven exciter furnishing exciting current at 20 volts. The exciter runs at 1,650 revs. per min.

The above motor is started by means of a grid resistance starter having seven steps and a total resistance of 6 ohms.

The auto-synchronous motor described

above has the advantages of both the synchronous and slip-ring induction type machines and in design has many points in common with the latter.

The motor is started in a similar manner to an ordinary slip ring induction motor, that is by connecting a resistance across the slip rings and gradually cutting it out step by step as the speed is built up, until at full load speed the slip rings are short circuited. The exciter is then connected to the slip rings by means of a double-throw switch, the starting resistance at the same time being disconnected.

The motor then synchronizes itself and will operate with the same characteristics as a synchronous machine the amount of power factor correction being controlled by the varying of the voltage of the exciter.

If for any reason the exciter should become damaged the motor will operate as a straight induction machine, and should a heavy overload be thrown on the motor when running synchronous, the motor will not stop but will continue to run as an induction motor until the disturbing conditions are removed and it has the opportunity to speed up into synchronism again.

The Canadian Westinghouse Co. installed the second 2,200-volt 25-cycle, 3-phase motor which is rated at 350 k.v.a. This motor also runs at 750 revs. per min. and is fitted with a 3.5 kw. exciter running at 1,400 revs. per min. and having a nominal voltage of 125.

Switching and Controlling Apparatus

The switchboard is divided into two panels, one for each machine. The panel controlling the Swedish General Electric machine is equipped with line ammeter, exciter ammeter and power factor indicating meter, together with the usual exciter field rheostat and other controlling apparatus. A switchboard type hand-operated oil switch forms part of the equipment and is fitted with an overload and no voltage release relay.

Placed on this panel and metering the whole power supply are two Westinghouse graphic meters, one a recording wattmeter and the other a recording power factor meter.

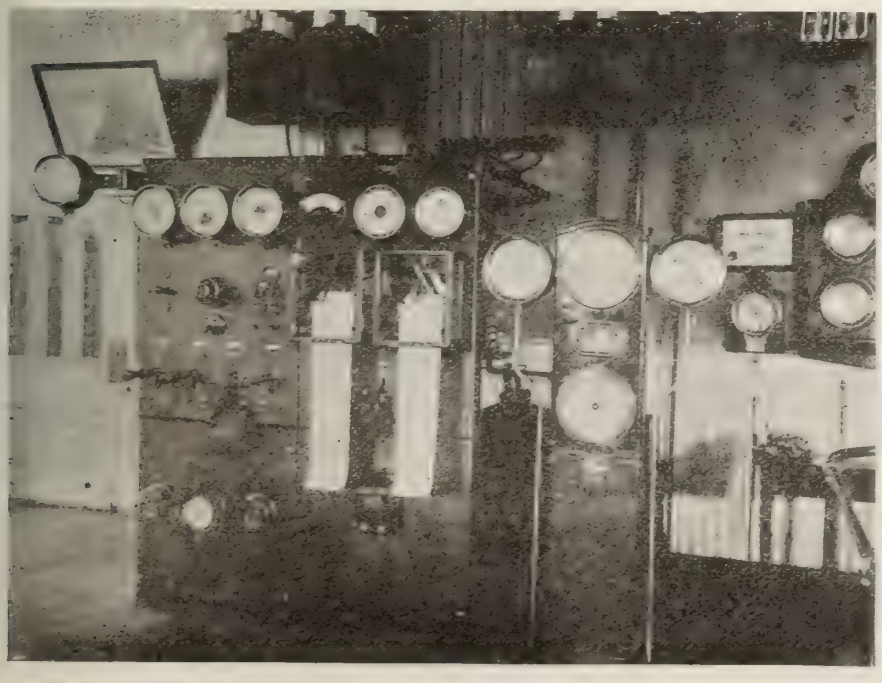
The Westinghouse unit is controlled by the remaining switchboard panel which is also equipped with the usual ammeters, power factor indicator, exciter rheostat and other equipment.

This unit is started by means of auto-transformers placed behind the board and connected to starting switches mounted on the wall well out of reach and remote controlled from the switchboard. These switches are type B Westinghouse oil switches; three are provided, two for the starting positions and the third for the running position. Westinghouse type C.O. relays control this unit.

Water Indicating and Recording Instruments

The city water consumption is very completely recorded by a 10-in. Venturi meter unit, built and installed by the Builders' Iron Foundry, Providence. This meter has a five inch throat and is equipped with dials showing the total volume of water pumped and the rate of flow. A graphic recording dial also forms part of the equipment by means of which an accurate record of the water pumped at any period is maintained.

Bristol recording meter is installed which gives a continuous record of the pressure carried at all times and the value of these various features has been amply proven when disputes have arisen as to the pressure when fires have occurred.



VIEW OF SWITCHBOARD CONTROLLING SYNCHRONOUS MOTORS WITH VENTURI METER ON THE RIGHT.

Distributing System

A standpipe located on the highest of the hills that encircle the city, about 1½ miles from the pumping station, forms part of the waterworks system. When full this standpipe contains 220,000 gallons. The piping system is so arranged that the standpipe can be cut off from the city mains and pumps, in this case delivering direct to the mains, relief valves being provided for proper operation and avoidance of water impact.

The water mains comprise a total length of 32½ miles and vary from 18 in. to 1½ in. in size, the major portion being of 4 in. size. Some steel pipe has been laid at various times but having been severely corroded in places it has been taken up as far as possible and replaced by cast iron. This improvement has resulted in a remarkable saving in the volume of water pumped.

Historical

On several occasions previous to the year 1890 by-laws for various amounts had been submitted to and defeated by the ratepayers of the town, and it was only in that year that sufficient money was voted by the electors for the purpose of constructing the present system.

In the following year contracts were let to the Goldie & McCulloch Co. of Galt for the equipment first installed. This comprised the pumping machinery, hydrants, valves and standpipe. The excavating and laying of the water mains was let to another contractor. Willis Chipman, Esq., was the engineer employed by the corporation for the supervision of the installation.

Since 1891 several bylaws have been carried at various times for the enlarging of the waterworks system and the purchase of additional pumping equipment and the waterworks owes its present excellent and efficient equipment to the public spirit of the community and to those who have ably conducted its affairs from the beginning. From the inception of the system until the year 1902 the waterworks was operated by a committee of the city council and in that year a board of commissioners was formed, of which Dr. J. H. Radford was elected chairman. Dr. Radford has been intimately associated with the waterworks from the beginning. Mr. R. B. McGregor is the present chairman of the board of commissioners, having been elected last year on the retirement of Dr. Radford. The present superintendent of the plant, Mr. P. H. Cowan, has been connected with the system since its beginning, a service of 27 years, and it is through his courtesy that the present account of the plant is written.

Mr. W. S. Fulton, the chief engineer, has been with the system for twenty-two years this June, and his associates in the operation of the plant are Messrs. J. Lockie and D. Wilson.

Canada's Water Powers: Their Relation to the Fuel Situation*

By
J. B. CHALLIES**

AT first "blush" it might appear that water power has only an indirect and limited connection with the recent critical fuel shortage, which through suspended effort has caused temporary industrial stagnation and local domestic hardships of enormous extent and involving great financial loss. Even a casual general survey of our fuel-power requirements, however, will indicate that not only has water power a very direct and important bearing on the present situation, but that water power must, in the future, take a very much greater share in our fuel-power burdens.

It is axiomatic that our heat, light and power needs must be considered as one great national problem, and also that Canada's domestic and industrial development depends primarily on the co-ordinated use of all the fuel-power resources of the Dominion.

Development along independent and divergent lines has, in the past, prevented adequate correlation of the great Canadian industries of fuel production and hydro-power supply. There is now, however, as a result of the fuel shortage, a consensus of opinion among men familiar with fuel and hydro-power matters in Canada that there is between these allied industries enormous scope

REMARKS

This compilation is based on 1916 figures. Consumption areas became somewhat distorted because 8,000,000 tons, or about ⅛ of the consumption is railway coal, and as such is carried from province to province as traffic necessitates.

Tonnages. (1) Are from Mines and other reports of provinces concerned.
(2) Are from combinations of reports of provinces concerned.
(3) Are calculated, allocating the tonnage according to population and known consumption, both imported and domestic; deductions and additions being made accordingly for domestic and imported tonnages in order to arrive at a reasonable figure. These figures cannot be obtained direct from any Government report.

Differences in totals are accounted for partly by taking arbitrary figures in some cases for purposes of calculation and by different methods of tabulation and statistics.

NOTE: Basic data compiled and tabulated by Mr. J. F. E. Brown, Mining Engineer.

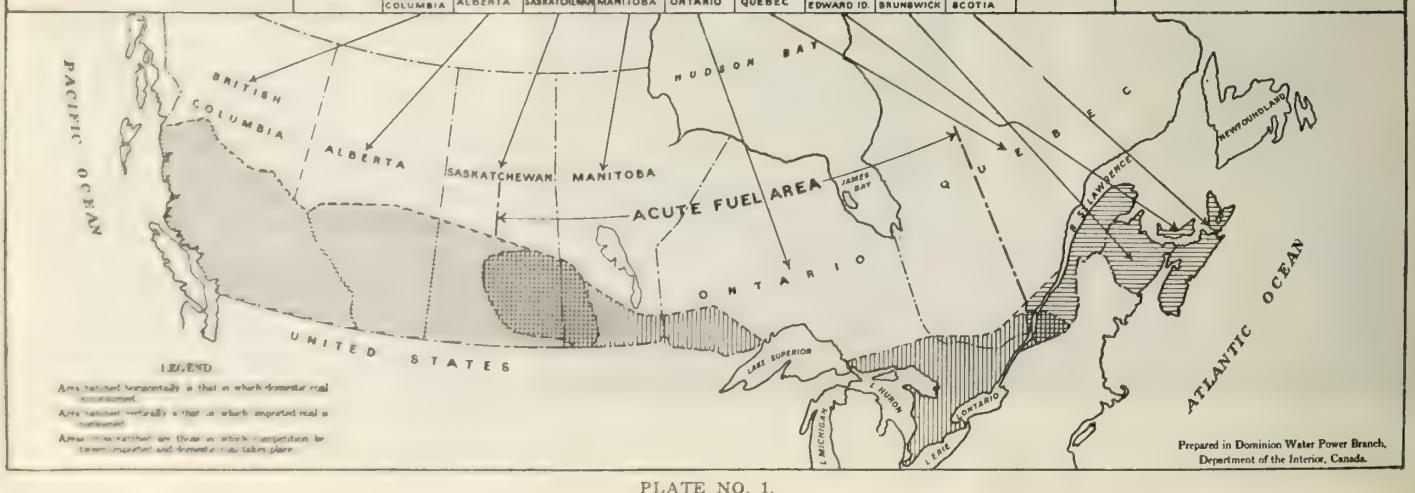

PLATE NO. 1.

for national co-operation which would be conducive to their mutual advantage, as well as to the common weal.

I propose to show: First—That water power must take a very prominent part if the best use of the varied fuel-power resources of Canada is to be achieved, and Second—That there must be evolved a national master fuel-power policy which will realize the best possible co-ordinated and concomitant development and use of all the fuel-power resources of the Dominion.

Canada's Production and Consumption of Coal

Plate No. 1 represents the coal consumption and production in Canada. The tabulated statement on the top of the plate summarizes the consumption in the various provinces of the different classes of coals, both domestic and imported. The greatest consumption is in central Canada, including the provinces of Manitoba, Ontario and Quebec. Coal production is greatest in the extreme western and eastern provinces. British Columgia and Alberta on the one hand and Nova Scotia on the other not only meet their own coal requirements, but produce a very considerable overplus for consumption in the contiguous portions of Central Canada. The central provinces, Manitoba, Ontario and Quebec, are almost wholly dependent on outside sources, mainly imported coals. This is clearly shown by the hatched areas on the map, the horizontal hatching covering the areas which produce their own needs, the vertical hatching covering the areas which are dependent. Where there is cross-hatching both Canadian and imported coals are consumed. It is to be observed that Central Canada, where consumption is greatest, is non-productive. This I have termed the "acute fuel area" of Canada.

Canada Imports Coal and Exports Coal

This "acute fuel area" is now dependent for domestic requirements mainly upon Pennsylvania anthracite and for industrial needs upon American bituminous coals, as well as upon Canadian water power. So far as domestic heating requirements are concerned, Mr. Dick, the consulting mining engineer of the Canadian Conservation Commission, in hispaper on the "Rational Development of Canadian Coal Resources" has pointed out the possibilities of the Western portion of the "acute fuel area" being furnished with briquetted lignite from the prairie provinces. Mr. Stansfield, of the Dominion Miner Branch, in his paper on "The Low Temperature Carbonization and Briquetting of Bituminous Coal," has pointed out the possibilities of meeting the domestic heating requirements of the Eastern portion of the "acute fuel area" by the product from the low temperature carbonization of Nova Scotia bituminous coals. Although both these processes are proven to be practicable, they are as yet in their formative or agitational stage and some considerable time must elapse before they can be placed on a commercial basis to furnish sufficient fuel to substitute for any large portion of the Pennsylvania anthracite now imported for domestic heating. There is at the present time no available supply, even in small quantities, of a Canadian coal fuel to take the place of imported anthracite. Nevertheless, this "acute fuel area" can eventually be made independent of foreign fuel imports and Canada can become self-sustaining, at any rate, in respect of her domestic heating requirements. There must, as a necessary preliminary, be a national, co-ordinated development and use of all the available fuel and power producing agencies in the Dominion. Such a co-ordination must be a matter of gradual evolution and adoption, and will to a great extent hinge on whether Canada can reasonably expect assured fuel imports from the United States for a considerable period in the future.

As we are now exporting large quantities of coals from British Columbia and Nova Scotia into adjacent States of the Union and as we are also exporting about 275,000 horse power of electric

SOURCE OF INFORMATION The basis of the table is the paper by M. Arthur Surveyer Consulting Engineer, Montreal, read before the Canadian Society of Civil Engineers Subsequent information obtained by Mr H E.M Kensit and Mr. A. M. Beale, of the Dominion Water Power Branch, is incorporated The table is not absolutely correct, but indicates a reasonable summary of the situation.

TABLE GIVING WATER POWERS IN EUROPE AND AMERICA.

energy, equal in value to about 3,000,000 tons of coal, it is obvious the United States cannot afford to place a sudden and complete embargo on coal exportation to Canada. The two countries must deal with each other at least upon a basis of quid pro quo. Providing Canada has her own fuel resources under strict national control, this power exportation should assure her an importation of sufficient coal to tide over any readjustment period necessary to permit of an ultimate dependence on Canadian sources of fuel and power.

KABABEKA FALLS, KAMINISTIQUIA RIVER.

The exportation in the past of Canadian electric energy has not been without compensating advantages. An assured United States market for Canadian power loads has enabled the financing and completion of several hydro-electric projects, the construction of which, so far as domestic markets alone are concerned, would not have been warranted at the time. The initial United States power load has, therefore, made it possible for the domestic market to reap all the benefits of available hydro-electric energy many years sooner than otherwise would have been possible.

While Canada has been receiving far more value in her coal importation than she has given in her power exportation the advantage is rapidly disappearing. It is reasonable to expect that the tendency will be for hydro-power exportation to increase and for coal importation to decrease. The time may come, and in the near future, when the balance will be against Canada.

It is, therefore, imperative that every proposal for increase in the exportation of power be carefully considered from a broad, national standpoint. Such consideration involves the evolution of a formula with regard to power exportations which will have cognizance of Canada's fuel-power needs generally.

We must face the fact that for some time to come we shall require to import United States coal, and that in turn therefor we can, under proper conditions of recovery, safely and profitably export some of our surplus hydro-electric energy.

Mr. B. F. Haanel, Chief of the Fuel Testing Division, Department of Mines, in his clear and comprehensive paper on the "Fuels of Canada," describes the nature, location and extent of our varied, available fuel resources. Mr. Haanel affirms that, while the problems associat-

ed with the distribution of fuel to the various parts of Canada are exceedingly complex and the strictest conservation must be practised, the Dominion is endowed with fuel deposits on such a magnificent scale that all that is necessary is their proper exploitation and economic use for the country to be eventually practically independent of foreign sources of fuel. Mr. Haanel is particularly emphatic that Canada need not go abroad for fuel for household use, if her own fuel resources are properly exploited.

The problem of Canada's fuel needs outside of the "acute fuel area" offers little difficulty, owing to an abundance of both coal and water power. It is simply a matter of efficient and effective use of available resources. Within the "acute fuel area," however, the problem is pressing and prodigious. It resolves itself into two parts, first, provision for domestic or household heating consumption; second, provision for industrial requirements.

Substitutes for Anthracite for Domestic Needs

The requirements for fuel for general household use are, at the present time, furnished by American anthracite; over 4,000,000 tons were used in 1916. Competent experts declare the anthracite coal fields of the United States are in measurable distance of exhaustion and that the supply will not last a hundred years. Having in mind the ever-increasing demands within their own borders for this fuel and the rapid decrease in quality as the supply becomes exhausted, responsible fuel advisers of the United States Government have seriously urged the establishment of an embargo against exportation of anthracite. We in Canada must realize that our supply of this fuel may be gradually restricted. It is, therefore, essential that we, without delay, consider what can be accomplished in the production of a suitable substitute for the United States anthracite.

Substitution of Hydro Power for Coal

The industrial requirements are now met by Canadian hydro power and United States bituminous coal. About 14,000,000 tons were consumed in 1916 for this purpose in the "acute fuel area."

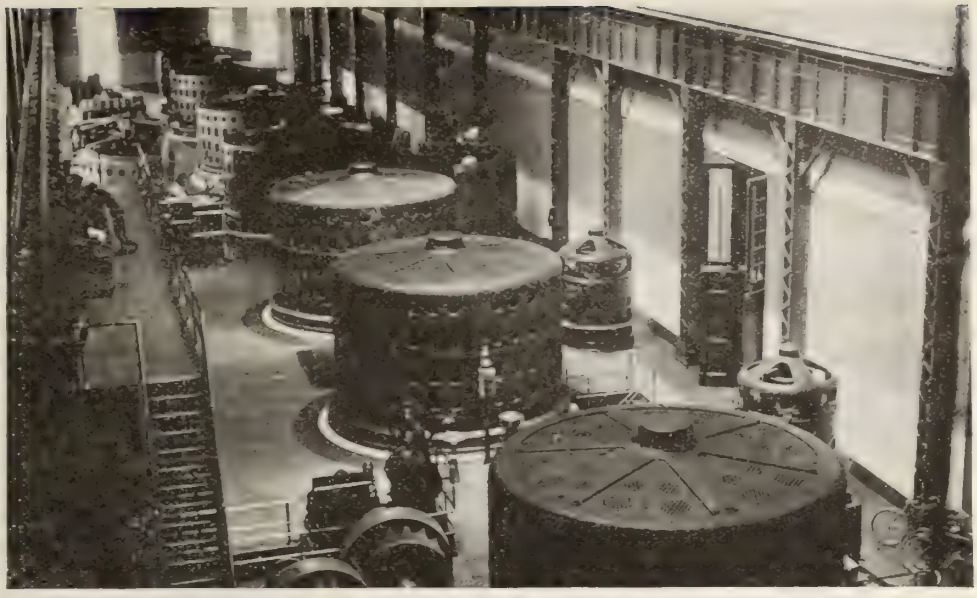
Owing to the large reserves of bituminous coal in Pennsylvania, this class of fuel will probably be available to the "acute fuel area" of Canada for many years. Although not immediately necessary, the ultimate substitution of bituminous coals must nevertheless, be seriously considered. Water power will be the main means of such substitution. The industrial fuel problem, therefore, in the "acute fuel area" becomes largely a matter of substitution of hydro power for fuel power.

Electrification of railways—especially terminals with adjacent engine divisions—would save enormous consumption of bituminous coal and relieve our transportation systems of their greatest burden.

It is estimated that something like 9,000,000 tons of coal was consumed by our railroads in the year 1917. Judging from the results obtained from the electrical operation of railroads in the United States, it would be possible to save at least two-thirds of this coal if electric locomotives were substituted for the present steam locomotives.

This year there would be a saving of 6,000,000 tons of coal in one year, and would require about 900,000 water horse power.

Electrification of steam roads at this juncture is not advocated. Under normal conditions, however, and in certain districts, as in western Ontario, electrification will become an economic necessity in a few years.



POWER HOUSE OF ELECTRICAL DEVELOPMENT COMPANY, NIAGARA FALLS.

The relation between developed water power and the coal production and consumption in the various provinces is represented on Plate 2. It is interesting to note that in the "acute fuel area" there is about as much water power developed, so far as coal value is concerned, as there is coal consumed. It is portentous that the bulk of our water power production at the present time is within the "acute fuel area," and it is reassuring to know that our largest and most important potential water powers are located within transmission range of present congested industrial districts within the "acute fuel area."

PLATE NO. 4.

production of hydro power in Canada has undoubtedly been an industrial achievement and an engineering triumph worthy of our nation. In the short space of about twenty-five years, there has been developed and put in use nearly 1,800,000 water horse power. A tabulated statement (see Plate No. 3) of the water power development in other countries, compiled recently from all available data, shows the universal importance of this resource and indicates the splendid comparative position Canada enjoys in both potential and developed water power. The present per capita power development in Canada is larger than all other countries except Norway. It is the same with respect to our known undeveloped water power. No country enjoys to a greater degree the benefits of cheap, dependable hydro power, and no country has had these benefits more universally applied for municipal, industrial and domestic use.

Fortunate Location of Our Water Powers

The outstanding feature of the water powers of Canada is their fortunate location with respect to existing commercial centres. Within economic transmission range of practically every important city from the Atlantic to the Pacific, except those in the Central Western Prairies, there are clustered water power sites, which will meet the probable demands for hydro-power for generations. The following table, prepared by the Dominion Water Power Branch indicates, reasonably accurately, the provincial distribution of the developed and undeveloped water powers within the settled portions of the Dominion.

Province	Available. Power	Developed. Power
Ontario	5,800,000	789,466
Quebec	6,000,000	520,000
Novia Scotia	100,000	21,412
New Brunswick	300,000	13,390
Prince Edward Is.	3,000	500
Manitoba	3,500,000	76,250
Saskatchewan		100
Alberta		32,860
British Columbia	3,000.000	269,620
Yukon	100,000	12,000
Total	18,803,000	1,735,598

To visualize the interdependence and interrelation of all the fuel-power agencies available in Canada, and to offer something as a basis for general discussion, I have prepared a chart (Plate No. 4). If the chart indicates any one thing it conclusively proves the immensity and complexity of the problems involved in effecting the co-ordinated, concomitant development and use of all our fuel-power resources. The chart shows that this can be best realized following the evolution of a national master fuel-power policy for all Canada.

PRINCIPLES AND OPERATION OF MODERN ELECTRICAL EQUIPMENT—V

By A. M. Pere.

IN last month's section it was shown that every conductor carrying an electric curent is surrounded by a magnetic field. Magnetism then may be caused by a flow of electricity and magnetism may in its turn cause a flow of electricity, but only under certain conditions.

In Fig. 1 is shown a coil of wire with a voltmeter, or other means of indicating a flow of electricity, in its circuit. If a bar magnet be suddenly plunged into the coil the voltmeter will show a decided deflection, swinging back to zero as the bar magnet comes to rest. If now the bar magnet be pulled out of the coil the voltmeter will again show a deflection but in the opposite direction, again coming to rest at zero as the magnet is far enough removed.

It may be surmised from this that a change in the strength or number of the magnetic lines of force passing through a coil of wire generates current and that this current persists only while such change is taking place.

The effect of changing magnetic strength is also shown in Fig. 2. As long as the switch is open the voltmeter shows no deflection. As soon as

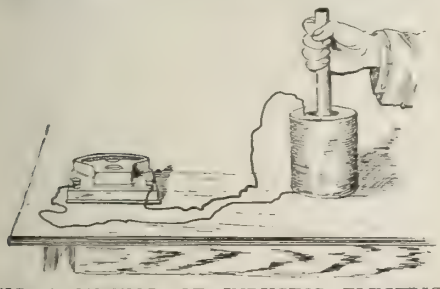

FIG. 1—METHOD OF INDUCING ELECTRIC CURRENT BY MEANS OF BAR MAGNET AND COIL OF WIRE.

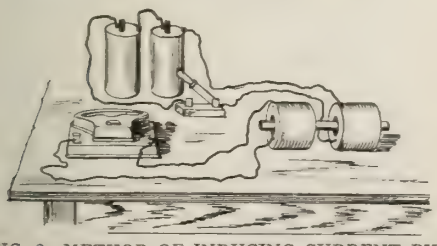

FIG. 2—METHOD OF INDUCING CURRENT BY CHANGING THE MAGNETIC FLUX OF AN ELECTRO MAGNET.

it is closed, however, it will be noticed that a sudden deflection takes place, the indicator quickly returning to zero. On opening the battery circuit the needle again deflects, and again returns to zero.

Motion of a Conductor in a Magnetic Field

A magnet and a conductor carrying a current of electricity exert a mutual force on each other or in other words each tends to produce motion in the other. The converse of this effect is also true, so that when a conductor is moved in a magnetic field in such a manner that it cuts the magnetic lines of force, an electro-motive force is generated in the conductor which tends to cause a flow of current. It must be remembered that in each case the magnetism, while it may be altered in distribution as regards the pole faces is not changed in strength, that is, the magnet is not weakened by the generation of an e.m.f. in a conductor. The energy necessary for this is derived from the

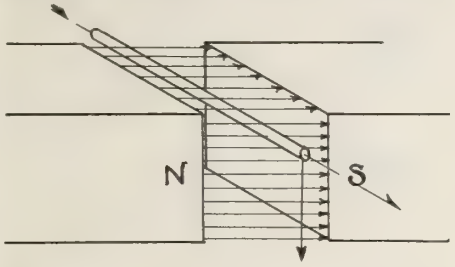

FIG. 3—DIAGRAM ILLUSTRATING THE RELATION BETWEEN THE DIRECTIONS OF MAGNETIC FLUX AND CURRENT PRODUCED BY MOVING CONDUCTOR THROUGH A MAGNETIC FIELD.

work necessary in moving the conductor.

The action of dynamos and motors is explained in the statements given above and the direction of the lines of force, the direction of the current and the direction of movement all bear a fixed relation to each other which is different in the dynamo and motor.

This relation for the **dynamo** is shown in Fig. 3. A magnetic field is shown with the lines of magnetic force proceeding from the north pole to the south pole. If the conductor shown is moved in the downward sense an e.m.f. will be generated which will tend to cause a current to flow in a direction indicated by the arrow. If the direction of motion or magnetic flux be changed the current will flow in the opposite direction and if both be changed together the current direction will remain as before.

Fig. 4 shows a similar arrangement to Fig. 3 but with a closed coil of wire. In this case it may be said that the e.m.f. is generated by the variation in the number of lines of force linking through the coil and this conception explains the action of the two arrangements shown in Figs. 1 and 2 only in Fig. 1 the magnet is moved through the coil and in Fig. 2 the strength of the magnetism is varied.

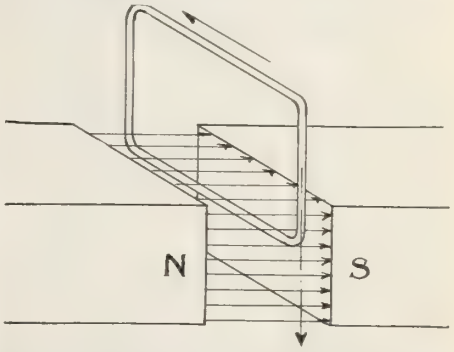

FIG. 4—CURRENT IS GENERATED IN A COIL WHEN PASSED THROUGH A MAGNETIC FIELD.

Dynamos and Motors

A simple and easily remembered means of recalling the relation of these three quantities is shown in Fig. 6.

The **right** hand is shown and if the forefinger be taken as representing the lines of force, and the thumb as representing the direction in which the conductor is moved, then the middle finger shown pointing downwards will represent the direction in which the current will flow.

The relation shown in Fig. 3 for the dynamo is not correct for the motor. When a current is sent through the wire the direction in which it will tend to move will be directly opposite to that shown and the wire will move upwards of its own accord instead of being forced downwards by an exterior force.

This relation for the **motor** may be remembered in a similar manner to that used for the dynamo, only instead of the right hand the left is used. Fig. 7 shows this. The left hand is shown with the forefinger pointing in the direction of the magnetic flux and the middle finger pointing in the direction in which the current flows. The thumb indicates the direction in which the conductor will move under these conditions.

Magnetic Drag

As an aid to understanding the principal underlying the action of the dynamo and motor, Fig. 5 is given. In this illustration the conductor is shown in the centre between the poles of a magnet. The direction of the current flowing through it is assumed to be toward the observer, as shown by the dot at the centre, remembering the convention as to the arrow, the dot meaning

towards and a cross away from the observer. The magnetic field due to a flow of current is shown in direction by the two circles around the conductor,

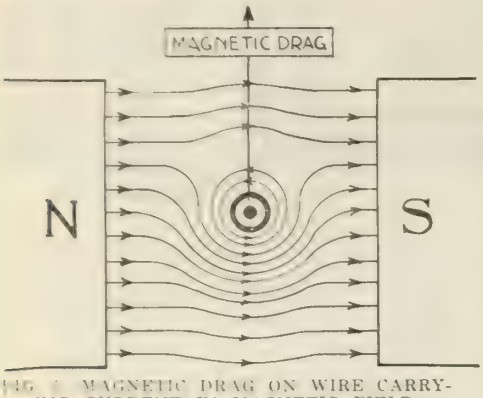

FIG. 6—MAGNETIC DRAG ON WIRE CARRYING CURRENT IN MAGNETIC FIELD.

while the direction of the field due to the magnets is shown by the remaining curved lines. This field will be distorted in the manner shown for the magnetic field due to the conductor opposes the lines of force above the centre of the conductor and reinforces those below.

The resulting distortion of the field will have a tendency to push the conductor up in the direction shown by the arrow much as if the lines of force were stretched bands of India-rubber. In the motor the current is sent through the wire from an outside source and the

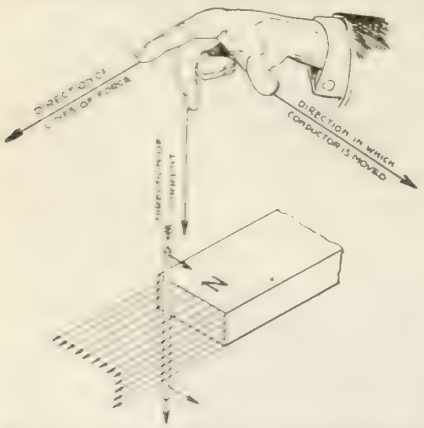

FIG. 6—FLUX CURRENT RELATIONS IN THE DYNAMO AND RIGHT HAND RULE FOR REMEMBERING SAME.

conductor is free to move in the direction indicated but in the dynamo the conductor is forced to move in the opposite direction or downwards, although it resists this movement.

In other words, in the motor the directions of the tendency to move and the actual movement are the same, while in the dynamo they are opposite and the magnetic drag may be spoken of as the resisting force which absorbs the work necessary in rotating the armature.

In the dynamo not only does the direction of the generated e.m.f. depend upon the directions of the magnetic flux and the motion but its strength varies as the speed with which the conductor moves and with the strength of the magnetic field. That is to say, if the speed with which the conductor moves were doubled the voltage generated would also be doubled and if the flux were doubled while the speed remained constant the voltage would be increased to the same extent. If the speed and flux were both doubled the voltage would be quadrupled.

Function of the Commutator

In Fig. 8 is shown a dynamo reduced to the simplest elements possible, a pair of poles, a single loop of wire and a two-part commutator. If the loop turns as shown by the arrow the right hand side will move upwards and the e.m.f. generated will be away from the observer remembering Fig. 7. The left hand side of the loop will be moving downwards and will have an e.m.f. generated in it opposite to that in the right hand side or towards the observer.

These two induced voltages will reinforce each other as is readily seen and if brushes are provided current will be delivered to an outside resistance or other means of putting it to useful work.

It is seen that each side of the loop alternately comes under the influence of the north and south poles and that no matter which side of the loop is near the north pole the e.m.f. generated in it, at this position, will always be towards the observer and that the commutator segment which happens, at this particular instant to be towards the left, will always be of the same polarity or positive. The right hand commutator

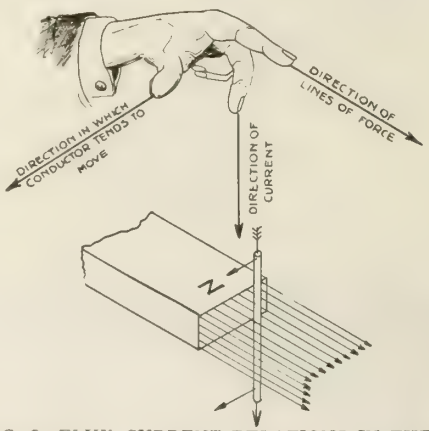

FIG. 7—FLUX CURRENT RELATIONS IN THE MOTOR AND LEFT HAND RULE FOR REMEMBERING SAME.

segment and the side of the loop which is connected to it, being in the field of the south pole will always have a negative polarity.

The brushes, by rubbing on the commutator (see Fig. 8) form not only a path for the current to flow to and from the armature but serve also to give a continuous or uni-directional current.

If instead of a split commutator two

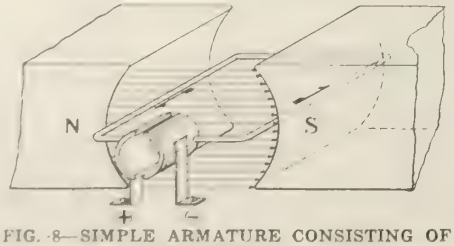

FIG. 8—SIMPLE ARMATURE CONSISTING OF ONLY ONE COIL.

rings had been connected up, one to each end of the coil, an alternating current would be delivered for each side of the loop would have a current flow-

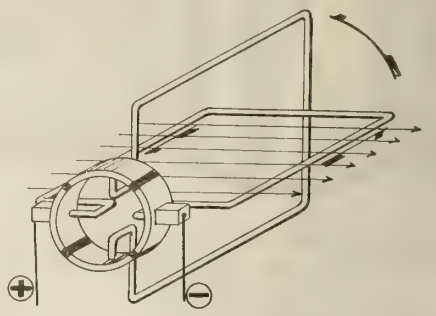

FIG. 9—ARMATURE CONSISTING OF TWO COILS.

ing in it first one way and then the other as it came under the influence of first one pole and then the other.

Multiple Coil Armatures

If two coils of wire similar to the one described above be mounted on an axis at right angles to each other with the four terminals of each coil connected to a four-part commutator as shown in Fig. 9, then the e.m.f. generated will be more nearly uniform in value. Commercial machines having large numbers of coils give an almost uniform current, and in the case of a motor the large numbers of coils present gives a uniform turning movement or torque.

Answers to Last Month's Problems

1. The flux generated in a magnet flows out of the north pole and through the surrounding air or other medium into the south pole.

2. The north magnetic pole of the earth does not correspond to the north pole of a bar magnet as regards the direction of flux travel. The difference may be easily kept in mind by calling the north pole of the magnet the north seeking pole and remembering that the flux travels away from it and into the north pole of the earth.

4. The magnetism flows in a clockwise direction around the wire when the current flows away from the observer and in the opposite direction when the current is reversed.

5. The coiling of a conductor into a coil increases the magnetic flux. In general it may be said that the flux generated is directly proportional to the number of turns if the iron is unsaturated. See the section on ampere turns in part IV.

6. The right hand may be used as a means of determining the polarity of a solenoid. The fingers are extended in the direction in which the current flows around the coil and the thumb extended along the axis of the coil points towards the north pole.

7. Ampere turns is an expression denoting the product of the number of amperes flowing through a coil of wire by the number of turns of which the coil is composed.

8. The number of ampere turns will be $25 \times 100 = 2500$.

This Month's Problems

1. In what manner may a current of electricity be generated in a coil of wire by the action of a magnet. What explanation would you give as to the cause of this generation of e.m.f.

2. What explanation would you give as to the cause of the actions of generators and motors.

3. Without looking at the text, recall to mind the conventions used in remembering the relations between the directions of the magnetic flux, current, and movement of conductor in the generator and motor and in this connection remember that it is important not to get the two conventions mixed.

4. Read over again the section on magnetic drag and note the explanation for the different actions of the conductor in the generator and motor.

5. In the generator how does the voltage generated vary when (a) the speed is varied; (b) the strength of the magnetic field is varied; (c) when both are varied at the same time.

CANADIAN ELECTRICAL ASSOCIATION MEET IN OTTAWA

The twenty-eighth meeting of the Canadian Electrical Association was held at the Chateau Laurier, Ottawa, on June 21, a large attendance being had in view of the present condition of the Canadian electrical industry

Condition of Canadian Utilities

The general conditions obtaining in the central-station industry throughout the eastern section of Canada were reflected in the address of D. H. McDougall of Toronto, the president of the association. Difficulties in obtaining coal and money are as common in Canada as they are in the United States, and the necessity for higher rates is just as pressing. Speaking of the immediate problems, Mr. McDougall said:

"The war and its accompanying sacrifices and hardships have made it necessary that each one of us should assume additional burdens and responsibilities. Our industry has had imposed on it additional duties in the way of operating problems and overloads that required all the skill, nerve and ingenuity that we could muster, and our staffs have been depleted further by conscription and the other war drains, making the maintenance of service a very difficult matter.

"Few of us are able to finance any new extensions to our properties or maturing bond issues. This handicap has been largely met by charging customers the cost of line extensions and by intensifying loads on present lines. Station increases have been almost impossible to finance. In some quarters this has been offset by taking on off-peak business, and this has required the study of factory conditions to educate customers to the necessity and possibility of such methods of operation. The result has been that higher load factors are experienced and some plants have been operated at a load factor deemed impossible even two or three years ago.

"The next difficulty has been with our employees, whose numbers have been decimated by military service, to which they have willingly responded, and by conscription, which I believe has affected us so far in a minor degree.

"I think I am safe in saying that great disorganization on account of these wholesale changes in staffs has only been averted by the loyalty and unselfish performance of duty of those who for one reason or other were unable to answer the call of the bugle.

The Hydroelectric Power Commission

"The outstanding example of failure to live up to contract obligations in the service of electric power in Canada during the past year is the case of the Hydroelectric Commission of Ontario, which, with an unprecedented lack of foresight, made contracts for larger amounts of power than it was able to supply. The total amount of this shortage has been stated to be 100,000 h.p., but, unlike the members of this association, the commission has so far been able to escape the consequences of this selling short of power, as it has refused to recognize the claims of its customers, based on the solemn contracts signed by it, and has pleaded that its shortage has been caused by the war.

"It is hard to believe that such immorality would be protected by the crown and that millions of dollars invested in plants depending on government contracts for their power should be shut down when many of them would otherwise be turning out munitions and other war necessities but for this breach of faith.

"The commission is able to secure large sums for construction work, amounting to about $2,000,000 a year, because its undertaking is supported by the government, although the works it is building cannot be of any service to the country for years to come, long after the war will be over. The amount of money expended by the Hydroelectric Commission so far in transmission and distribution plants is about $70.000,000, and the estimated amount of taxes lost to the people, which they would collect from privately owned companies with similar properties, is about $1.500.000 per year."

Other speakers at the morning session were T. C. Martin, secretary of the National Electric Light Association, who spoke of the work of the national body for the year and of its war committees; Willis MacLachlan of Toronto, who spoke on accident prevention, and with the assistance of operators from the Ottawa Electric Company, gave a demonstration of resuscitation from electric shock; A. A. Dion of Ottawa, whose report for the overhead-line committee dealt chiefly with the grounding of high-tension and secondary circuits, and J. F. Nield, of Toronto, who reported on electrical apparatus.

Four reports were made at the afternoon session, all of which were commented on. William Volkman of the Toronto Power Company reported on the changes made during the past year in the manufacture of meters. A part of the report was devoted to the determination of power factor, because with the load conditions and the extremely high cost of additions to line capacity any relief which might be obtained by improving the power factor of consumers' loads is of great importance. Three methods for determining the power factor of loads were outlined in detail.

H. E. Randall of Montreal reported on the commercial light and power sales and on the use of electricity during the past year. The great value of the central-station industry to the country and the important part it is accomplishing in the production of munitions, in solving the servant problem, in the conservation of fuel, man power and material, and in building up industrial conditions of Canada, were described in detail.

As the Canadian Electrical Association's representative on the National Electric Light Association's lighting sales bureau, E. N. Hyde of Montreal reported on industrial lighting conditions.

A very interesting report was presented by P. T. Davies of Montreal on rate research. It was pointed out that the obligations of customers in Canada to provide themselves with suitable electrical apparatus have been increased in view of the shortage of power and the high cost of machinery. Nearly all companies are requiring customers to keep power factors within reasonable limits at all times and to pay for any deficiencies.

Officers for the coming year were elected as follows: President, A. Monro Grier, Canadian Niagara Power Company, Toronto, Ont.; first vice-president, E. A. Dunlop, Pembroke, (Ont.) Electric Light Company; second vice-president, C. S. Bagg, Montreal Light, Heat & Power Company, Cons.; third vice-president, A. P. Doddridge, Quebec Railway, Light, Heat & Power Company; secretary-treasurer, W. Volkman, Toronto Electric Light Company. The managing committee comprises D. H. McDougall, Toronto Eelectric Light Company; J. S. Norris, Montreal Light, Heat & Power Company, Cons.; P. T. Davies, Southern Canada Power Company, Montreal; R. B. McDunnough, Quebec Railway, Light, Heat & Power Company; J. S. Gould, Citizens' Electric Light Company, Smith's Falls, Ont.; H. M. Hopper, St. John, (N.B.) Railway Company; L. Pratt, Dominion Power & Transmission Company, Hamilton, Ont.; J. B. Woodyatt, Southern Canada Power Company, Montreal; W. H. McIntyre, Ottawa Electric Company; R. J. Beaumont, Shawinigan Water & Power Company, Montreal; H. E. Randall, Shawinigan Water & Power Company; A. V. Gale, Hull (Que.) Electric Company; J. F. Nield, Toronto Electric Light Company, and the president of the N.E.L.A.

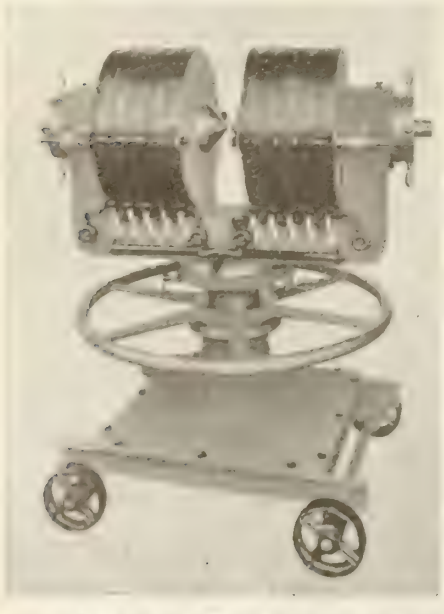
The proceedings ended with a banquet in the Chateau Laurier at which seventy-five were present. Addresses were made by the incoming president, A. Monro Grier, D. H. McDougall and John Murphy, electrical engineer of the Dominion Railway Commission.

A REMARKABLE SWISS HIGH POWER MAGNET

By F. R. A.

THE accompanying illustrations show the construction of a remarkable magnet developed at Oerlikon, Switzerland, by Prof. P. Weiss, of the Ateliers de Construction Oerlikon. This high power magnet, with 200,000 ampere turns, is utilized at l'Institute Fedral de Physique a Zurich, Switzerland. It has a diameter of 15 c. and an attractive force of 2,000 hg.

This powerful magnet has two coils, with 15 sections in each coil, and 1,600 turns of wire supplied with a current of 60 amperes. The resistance of each section is 49 ohms and for the excitation of the magnet about 18 kilowatts are required. The cooling coils may be noted in Fig. 2. The magnet shown in Fig. 3 has 150,000 ampere turns, and is in service at l'Ecole Normalle Superieure de Paris. It has two coils, with 10 sections in each coil and 75 turns on each bobbin, the current required being 25 amperes It will be noted that this magnet, therefore, has a total of 1,500 turns and a resistance of 2.5 ohms. A high power magnet of the Weiss design has been installed by the Department of Commerce and Labor at Washington, D.C. The points of these Swiss magnets are of fere-cobalt inserted in the pole, as indicated in drawing, Fig. 4. The diameter of the poles is 175 millimeters and the diameters of the ferro-cobalt points



HIGH POWER MAGNET OF 200,000 AMPERE-TURNS WITH COOLING COILS.

ITALIAN CHEMIST PROPHESIES "DAY OF LIGHT"

WHEN the rays of the sun strike the green leaves of a plant, carbonic acid gas and water vapor or moisture are gathered in from the air and these within the remarkable laboratory of every green leaf are turned into sugar. At the same time oxygen is set free, back into the air. The reaction requires heat, and the sun's rays provide it.

The plant operates other chemical factories and these transform sugar into starch, which is stored in the seeds to feed each sprouting plant until it gets big enough to grow green leaves and make sugar and starch for itself. Starch is also transformed within the plant into gums and cellulose, and the structural basis of wood is cellulose. Please observe also that the sun provides the heat for all of these reactions.

Fuel Combustion

When we burn wood or coal we reverse the process; we draw upon the oxygen that has been set free into the air when this or some other tree grew and we combine or burn it with the carbon acid gas and water again. That is the great cycle of vegetable life, beginning with carbonic acid gas and water and ending in carbonic acid gas and water. The reversed reaction gives off heat instead of requiring it, and that is why we burn wood or coal: to get the heat back that the sun provided long ago. White smoke is mostly steam and carbonic acid gas. Black smoke is mostly carbon that got frozen out in the fire or couldn't find oxygen enough to combine to carbonic acid gas again.

Professor Giacomo Ciamician, of Bologna, in an address before the Eighth International Congress of Applied Chemistry, asked why we use only the fossil energy of the sun—which is what we do when we burn coal. Why not get the power direct? If plants do this thing, he insisted there must be a way. There is plenty of water, it is easy to make carbon dioxide, and there is the sun. The point is, of course, to make available the radiant energy of the sun's rays and put it to use, which the plants can do and we cannot—as yet--for lack of adequate research

The professor felt sure, however, that this riddle will be solved some day, and then be made computations as to what we may do after the way has been discovered.

Using the sun for only six hours of every twenty - four on desert lands, and making generous allowances for good measure and waste, he concluded that the sun would deliver in energy taken direct from its rays, instead of by our roundabout method of recovering it by burning coal, the daily power value of 2,500 tons of coal per square mile. We mine in the United States about 600 million tons of coal a year. The desert of Sahara alone receives every day in solar energy the equivalent of six billion tons of coal.

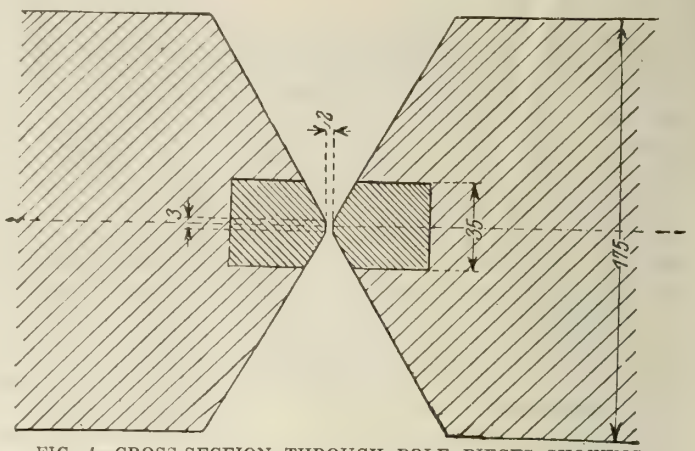


FIG. 4 CROSS-SECEION THROUGH POLE PIECES SHOWING FERRO COBALT POINTS.

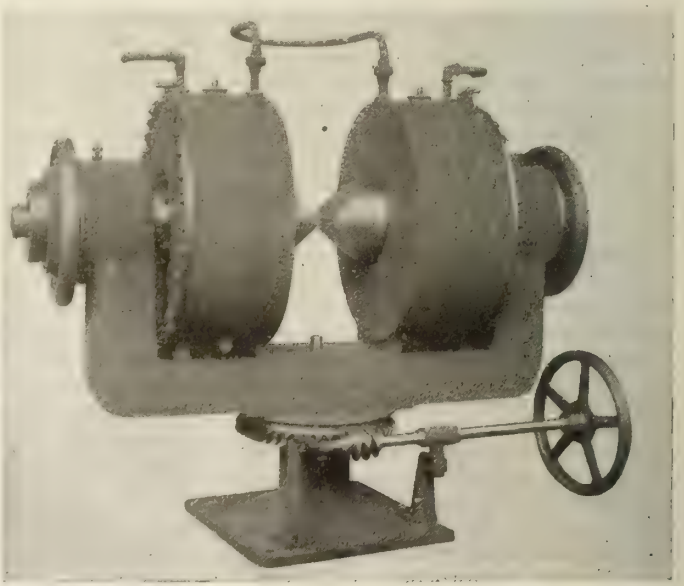
Looking Forward

Then he showed a long list of photochemical processes which indicate progress in research towards "The Day of Light,"—towards sun power. He prophesied that in time tropical countries will be thickly populated, that on their arid lands there will spring up industrial colonies without smoke or smokestacks but with forests of glass extending over their plains and glass buildings everywhere. Inside of these will take place those processes that are still the guarded secrets of trees and grass. But when these are mastered human industry will make them bear far more than nature does. Nature is not in a hurry and mankind is. So some day it may not even be necessary to use fuel any more or to worry about the supply or the price.



3—SIDE ELEVATION OF 150,000 AMPERE-TURN WEISS MAGNET.

Steam and Its Generation

THE NIGGER IN THE COAL PILE

By Robert June

THE big industries of Canada have made a discovery. They have learned that the profits of to-day depend very largely upon the economies that can be effected in production, and that the profits of to-morrow will depend entirely upon such economies. The recognition of this fact has come tardily to many, but now that they are "seized with the spirit," they are going after savings in every direction.

This is one reason why Big Business is as big as it is, and why the big fellows are absorbing the little ones.

It would not be correct to say, however, that the big industries are uniformly economical in regard to the operation of their power plants. Many of them are extremely wasteful. With every incentive to scrutinize power costs, and to put their power plants on the same basis as other producing departments of their factories, they have failed to exercise business-like supervision over their boiler rooms.

Neglect in Past

As a general proposition, the manufacturer has been so busy with sales problems and getting volume of production, that he has neglected one of the most important elements of profitable operation. He has wasted 25 per cent. of his fuel, largely because he has regarded his boiler room as a place of mystery, the chief function of which was to consume coal in endless quantities.

He has given his fireman an unlimited supply of coal and told him to go to it, and as long as the fireman has kept steam up, nothing has been said. The fireman, on his part, has considered that he has performed his full duty in keeping the pressure gauge at 150 pounds. It was what he was hired for. Nothing was said when he was engaged, about the quantity of coal he was to burn to keep the gauge at that mark. Coal, to him, has been a heavy black mineral, requiring a great deal of handling—nothing more. The boss has seen to it that it was delivered in whatever quantities he, the fireman, required and the boss has paid for it—so why should he worry.

The United States Bureau of Mines has been for a number of years engaged in obtaining and disseminating scientific information regarding the mining and consumption of coal and the results of the work have been of great value to technical engineers.

Six hundred million tons of coal was mined in the United States last year. It is predicted that 700,000,000 tons will be mined this year, and next year's production will likely be still greater. Of this quantity approximately 37 per cent., or 259,000,000 tons, will be burned in the production of steam and of this amount, fully 10 per cent. or 25,900,000 tons, will be imported to meet the demands of Canadian industry.

Amount of Waste

I have said that 25 per cent. of all coal so burned in the past has been wasted.

It is no secret.

David Moffat Myers knew it when he read his paper, "Preventable Waste of Coal," at the annual meeting of the American Society of Mechanical Engineers in New York, in December, 1917 Walter N. Polakov knew it in April of last year when he brought out the impending danger of a coal famine in a series of brilliant articles in the technical magazines. Jos. W. Hays knew it five years ago when he addressed to power plant operators his remarkable little brochure, "How to Build Up Furnace Efficiency." And scores of our ablest consulting and mechanical engineers, men of the type of F. A. Clark, chief engineer of the Toronto Power Company; A. S. Rutherford, manager Brunner Mond; H. H. Hutchinson, superintendent Canadian Explosives Company; C. W. E. Clarke of Stone and Webster; Frank R. Ford, of Ford, Bacon and Davis, and E. J. Buegler of Westinghouse, Church, Kerr Company, know it and have known it for years.

Each of these men has been successful in building up the operating efficiencies of the plants with which he has been associated and knows what can be accomplished. Each knows that the results attained in his plant could be attained in hundreds of others. It is one of the outstanding wonders in the history of the development of industry in Canada and the United States that a waste running into hundreds of millions of dollars annually should have been permitted carelessly to continue year after year through failure of the business executive to heed the commendations of his consulting engineer.

Preventable Waste

The preventable waste of fuel in the boiler furnaces of one steel mill recently investigated, amounted to 40,000 tons a year, which at $5 a ton would cost $200,000. This was a comparatively modern plant. The efficiency of boilers and furnaces in a 14-day test was 55 per cent. The load factor was unusually favorable to high efficiency and could readily be raised to 70 per cent. or over. This is only one example, and there are many more extreme cases. In one hand-fired plant the evaporation was raised from 6 to 9 pounds of water per pound of coal in a few days of instruction and continuously kept close to this higher mark with the help of coal and water measurements which were inaugurated. The saving was due exclusively to instruction and consequent better operation.

Another large concern, internationally famous, operates several good-sized plants that burn as high as 50,000 tons of coal per year. An elaborate bookkeeping system is in use, and petty expenses are kept down to a minimum, and the same policy is carried out in regard to the wages paid engineers and firemen. Although the cost of manufactured production is down to scientific perfection, but little attention is paid to the cost of the steam generated. The engineers are kept busy outside the boiler room. The master mechanic of the concern has a "test" made once in a while, and if the evaporation does not come up to expectation, the fault is laid to adverse running conditions and let go at that. A general increase of at least two pounds of evaporation per pound of coal could probably be effected in the plants of this concern, which would mean at least $25,000 saved every year—many times what it would cost to equip the different plants with necessary apparatus and pay the salary of a competent combustion engineer to look after their operation.

In two adjoining Ontario towns there are two brick plants. The smaller of the two plants burns eighteen tons of coal per day, the larger five.

In a western city there are two paper plants of approximately the same capacity. One burns three tons of coal per hour, and the other ten tons. The proprietor of the three-ton plant is getting rich and buying more plants. Some day he will buy the ten-ton plant and put it on a three-ton basis.

Increasing Dividends Through Fuel Savings

In another instance, the management of a large plant, facing sharp competition, came to a realization of the fact that every dollar in the coal pile has

to be skinned from the dividend pile, and began to take thought of its boiler room. Such things have happened before, but in this instance the thought was followed by action. The furnaces were placed in proper condition, provision was made for regular cleaning and close supervision, and the firemen were placed on a bonus system. Less than $4,000 was expended in making the change. Coal had cost this company $164.000 the preceding year. In spite of increased prices and increased production, the saving effected the first year amounted to $46 000 in real money, and the company declared its first ten per cent. dividend.

There is the case of the Smith and Jones Refractories Company. By redesigning the furnaces in this plant and adapting them to the fuel used and by substituting machine-fired grates, the consulting engineers succeeded in obtaining the same amount of steam with but 64 per cent. of the coal formerly used. This plant, when completed, was turned back to the same management that it had before with no further instructions. There were installed facilities for continuously determining the weight of the coal, ash and water used as well as the analysis of the furnace gases.

In another large Canadian plant, a similar saving in coal was effected. This plant has an aggregate capacity of over 5.000 nominal boiler horsepower, divided into 12 units. It was formerly operated with hand-fired shaking grates for which machine-fired grates were substituted with properly designed furnaces. The plant is now being operated continuously at 150 per cent. rating and is using no more fuel than it formerly did when being operated at two-thirds of its present output. The boiler-room force required to operate this altered plant is less than half of the number of men formerly employed. No change has been made in the management.

Where We Stand To-day—One Cause of the Car Shortage

The mining and distribution of coal in the United States, from which Canada draws its principle supply, have been placed under the supervision of the War Coal Board, in order more nearly to meet the crying needs of the country, to use the railroad facilities more efficiently, so that the present car shortage may be minimized, to apportion the coal in quantities and to uses deemed most expedient.

While this organized effort to bring about efficiency in the production and distribution of coal is being made, no parallel measures have been adopted to bring about a normal and practicable efficiency in its use, either for the United States or Canada. The hundreds of large plants which are consuming fuel wastefully, in many cases more wastefully and carelessly than ever before, are directly and needlessly causing a large fraction of the existing car shortage.

The saving or wasting of 25 per cent. of the coal consumption of any indus-

efficiency of its operating management. This percentage of saving relates exclusively to the boiler plant, to the production of steam, and does not include the large economies possible in connection with its distribution and use.

I refer to the boiler plant, particularly because it offers the more lucrative field for producing economies, and these with a minimum of alteration in physical equipment.

Under present conditions, a plant which carelessly operates at an efficiency of 40 to 50 per cent. receives from the Government the same consideration in the delivery of coal as the one whose efficiency is 70 to 75 per cent. An awakened public will certainly not permit this condition, with its needless waste of 60,000,000 tons of coal per year to continue.

What Is Coming

Power is one of the largest items of expense in most manufacturing businesses, and the cost of fuel represents on the average 70 per cent. of the cost of power. And the cost of fuel is going up. Nothing short of the discovery of a new source of power can stop the rising tendency of coal prices.

In 1850 our annual coal consumption was 300 pounds per capita. By 1870 it had jumped to 2,000 pounds, and twenty years later it was 5,000 pounds. In 1917 approximately six tons of coal was mined for every man, woman and child. And this was not enough. Our war machine has demanded for 1918 a production equal to seven tons per capita.

Will it get it? It may and it may not.

One Thing Is Certain—Coal Must Be Saved

The mining and distribution of our coal supply, the regulation of prices and the adjustment of financial and labor problems have already largely been placed under official administrative attention. But no parallel measures have been as yet adopted looking towards reduction of waste in connection with the utilization of coal. It is a foregone conclusion that this condition will not continue un-remedied.

The time is coming when the conservation of fuel will be rightfully and generally conceded to be a public, national matter, and the use and waste of fuel subject to regulation. Almost inevitably, a governmental commission will require from users a strict accounting of their stewardship of the B. T. U. intrusted to them; whether two, five or ten times the necessary amount is being used; not whether the individual is satisfied or chooses to waste, but rather the broader view of conservation that with waste the cost of fuel is made proportionately greater, more burdensome to others.

EDITOR'S NOTE.—This is the first in a series of articles by Mr. June, on Power Plant Management. Succeeding articles deal with coal and its selection, combustion of coal, influence of furnace design, various types of stokers, bonus system for firemen, abuse of steam, etc. Later articles sum up the best current practice in the business management of the power plant.

THE INFLUENCE OF THE POWER PLANT IN FACTORY DESIGN

In considering the layout of a factory and the equipment necessary for the generation and transmision of the power used one point is often overlooked. The cost of power is in many cases only a small part of the total cost of the manufactured article and it has been stated on figures obtained from a number of industrial plants that it is only from two to five per cent.

Factors Which Count

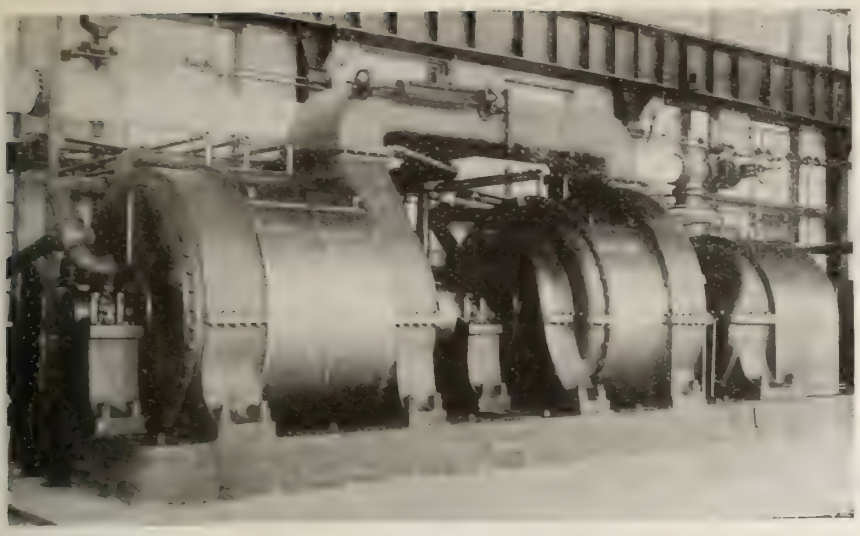
It is commonplace to say that tests and comparisons can be quoted to prove the superior economy of all types of power plant and transmission systems, and it is necessary to keep an open mind when listening to the advocates of particular schemes. The truth is that each system of power generation and transmission has its particular advantages and superior economy, and that maximum economy in works driving in a particular case may be obtained by a combination of two or more systems. Dealing with transmission systems where the plant is compact and conveniently arranged within a radius of 100 or 150 feet from the central power plant, mechanical transmission is most economical, while, with an increased radius, gas or electrical transmission has advantages, the former being the most enticing system from the point of view of thermal efficiency, but meantime having a more limited application. From this it will be understood that in small works and factories the most careful thought ought to be given to the works design in order to ensure a compact arrangement and efficient mechanical transmission. Where tools are set widely apart, electrical transmission with independent motors is economical, although where it is possible to have a group of tools in a works, an independent gas engine or electrical motor driving these through gearing is most economical than independent motors.

Individual and Group Driving

Where the amount of power required for individual machines is small it is almost always advisable to group them. That this conclusion is borne out in practice will be seen by examining the published descriptions of the electrification of several large engineering and shipbuilding establishments. From these descriptions it will be found that the average size of motor is steadily rising. The question of reliability and consequent need for stand-by plant is also important. Practically any one of these systems if properly installed can be regarded as reliable, but the subdivision secured by the use of motors or small gas engines has advantages. The chief advantages of the electrical transmission system are its adaptability and the ease with which it can be extended, and its chief drawback is its cost, a part of which at least is due to the refinements which have been introduced into electrical controlling and operating mechanism.

Prime Movers

The question of power generation like



SOUTHWORK RATEAU TYPE TURBINE OF LARGE CAPACITY.

the question of transmission depends for its solution upon the conditions of service. Where the power demand is very intermittent purchased electrical energy will be found to be the most economical. For a moderately steady demand up to about 100 to 150 b.h.p. the gas engine has no rival. Above this it is possible to purchase steam plants using highly superheated steam and furnishing power at an extremely low cost.

The units in the case of gas engine-driven generators may be of practically any size desired, while steam engine-driven units may be reciprocating engines up to 750 kilowatts, and steam turbines thereafter. Interesting results can be obtained from the combination of reciprocating engines with steam turbines, this combination giving a wide range of economical load at a modest capital cost, this advantage being got by cutting out the turbine from the lower loads and exhausting direct from the reciprocating sets to the condensors.

AMERICAN-RATEAU STEAM TURBINES

By I. N. S.

In the impulse type of turbine, few stages, or nozzle and bucket wheel elements, are required. Buckets are especially formed to economically transmit the energy of the steam through wheels to shaft; principal parts are few in number, and simple in design; delicate parts are avoided; and maximum of strength and reliability is obtained. The Southwark-Rateau turbine here described is built in three types; high pressure, low pressure and mixed flow, made for alternating current or direct current service with the generators either direct or gear-connected to the turbine.

The mixed flow governor maintains the speed of the turbine so nearly constant that it is unrivalled for use on turbo alternators of the mixed flow type. The ordinary speed controlled governor is entirely unsuited for this service, as the generator is invariably allowed to drop its load when the turbine changes from low to high pressure steam. With the Southwark-Smoot governor, however, no appreciable change in speed is observable during changing steam conditions.

High speed gears, of double spiral or herring bone type ,are used in these turbines. Gears are so carefully cut and assembled that they may be operated at highest speeds without undue noise or vibration; the speed of a high speed turbine may be reduced to that at which the machinery is driven, with economical operation and both driving and driven units, coupled together through medium of gears, will operate under most favorable conditions.

The buckets of the turbines are milled from a solid bar, and the material used is an alloy steel of great toughness and wear-resisting properties. Its design provides exceptional strength and absolutely prevents loss of efficiency even after many years of service. By this construction all strains, due to forging or punching, are avoided. The shrouding is integral with the buckets, and these are so firmly attached to the wheels that the loss of buckets is unknown.

The wheels on which the buckets are mounted are special steel forgings. They are machined all over to exact size, and are balanced with greatest care. Pressure equalizing holes are provided to prevent any end thrust due to unequal steam pressures caused by eddies. After mounting the buckets these wheels are shrunk upon the shafts so as to form practically a single piece of solid steel. The diaphragms are made of iron or steel castings, as may be most suitable. They are held in place by grooves turned in turbine casing, and are thus rendered perfectly solid and steam-tight. Steam leakage around the shaft is prevented by a packing of the latest design.

The nozzles are made in two forms. Where high pressures are encountered, nozzles are of bronze castings finished by hand, so as to present a perfectly smooth surface to steam flow. The larger nozzles, used in low-pressure stages, are of a special grade of sheet iron. They are cast directly into the diaphragms by a special process, which provides the perfectly smooth surface so essential to an efficient nozzle. All nozzles are brought to exact size by gauge before assembling in place. The importance of this feature can hardly be over-estimated, as a seemingly insignificant error here causes a serious loss of efficiency. The oiling system consists of oil rings and forced feed on the larger units, and of oil rings alone on the smaller. The bearings are provided with deep oil wells so as to insure a constant supply of clean oil.

The steam passages are arranged to prevent loss due to eddies and friction. The support provided for the shaft is worked out with great care. The top half of casing is removable with the top halves of all diaphragms without breaking any steam connection. The bearing shells may be removed for inspection or repair without disturbing any other part.

CENTRAL STATION VS. ISOLATED PLANT

THE controversy having to do with the respective merits of the central station and the isolated plant, in supplying power to industrial enterprises, has received a new impetus in the light of the problems of the present war. Centralization may be said to be the keynote of the age and the proposed schemes having to do with the establishing of enormous power plants at the mines and the distribution of the energy so created have much to commend them. This would free a large railroad tonnage for other purposes and would permit the utilization of every pound of coal mined to the best advantage.

The combustion of coal for the generation of power while allowing its valuable nitrogen content and other by-products to go to waste is inexcusable and it is to be expected that in the contemplated plants provision will be made for the conserving of this important natural resource by the establishment of by-product coke-ovens wherever possible.

In a country where fuel is hard to obtain and waterpower abundant it is manifestly to the interest of everyone concerned to make full use of this natural resource. To this extent it is better to take advantage of the central station's facilities for economical generation and distribution of power. But when the question of heating the industrial plant comes to the fore or where large quantities of steam are used in manufacturing processes the central station's advantage is very small indeed.

It is much better engineering practice to generate steam at a high enough pressure to utilize its inherent power in the steam engine or turbine and to use its remaining heat as required than it is to use almost the same amount of coal for heating and to purchase power generated at the cost of an additional amount of fuel.

It is an economic crime to burn coal for heating without taking advantage of its power-giving possibilities and it is this fact that renders the isolated plant successful in spite of its many inherent disadvantages. In this connection the use of induction generators, a recent development in hydraulic plants of small capacity, will probably offer a solution of the problem advantageous to the central station and the isolated plant alike. It is a characteristic of the induction generator that when connected with a central source of energy it needs no synchronizing or speed regulation and has no other complications requiring skilled supervision. A cheap type of prime mover is successful for its operation and its use would render available nearly 100 per cent. of the total heat value of the coal present in the steam at a low capital cost.

The central station would profit by the connection of this type of plant to its mains by being relieved of its winter peak and even in some cases by receiving power while the consumer would have all the advantages of central station energy in the summer months and cheap power during the remainder of the year.

ALL FOR NATURE AND NATURE FOR ALL

BEFORE another winter passes the possibilities attending a real coal famine will be brought home to many of us. It may be that personally we will not be physically inconvenienced but indirectly there will be many things to remind us that conditions are different from what they used to be, and careful thought will impress on us the truth that they never will the same again.

Political crises may come and go, questions involving taxes, tariffs, coinage, and social considerations generally may be decided and re-decided to meet the whims and fancies of parties in power so that ill-effects can be re-adjusted and inconveniences removed. But—interference with and misuse of natural resources bring their own reward. Nature out-Shylocks Shylock because she always gets her pound of flesh even though she may have to wait a thousand years for it.

Indiscretions of humanity in utilizing nature's resources have cost mankind untold sums and it is not putting it too strongly to say that the future conditions of existence of the human race are being decided now, and the decision is in two stages. First, is or is not man going to so conserve naturally recurring sources of power so that the human race will be independent of limited supplies of fuel? Second, are these sources of power to pass into the control of a select circle of individuals or be retained by the State as a national asset for the use of the people?

Suppose some clever, ambitious individual devised a scheme for shutting off sunlight and put up arbitrary rates for its supply irrespective of what his plant investment cost—in other words, got all it would stand. How long would the people stand for it? A reasonable amount of light and heat is necessary for every individual and as long as it can be obtained from any source whatever, it is a moral obligation of all responsible governments to see that it is supplied.

Association and Personal

C. A. S. E. CONVENTION

THE 29th annual convention of the Canadian Association of Stationary Engineers which was held at London, Ont., on June 25, 26, and 27, was generally conceded to have been one of the most successful since its inception, principally by reason of the fact that an important announcement was made by Dr. Riddell regarding the grading of engineers' certificates. The desirability of having graded certificates has been discussed at the conventions for a number of years but only recently has any material progress been made towards the attainment of this object. The announcement by Dr. Riddell was naturally received with much enthusiasm by the engineers who appointed a committee to work out the details in conjunction with Dr. Riddell and the Engineers' Board of Ontario of which body W. C. McGhie is chairman.

Another important matter discussed at the convention was the conservation of fuel. It was felt that the engineers, individually and collectively could do much towards conserving coal owing to the nature of their work and that great good towards this end could be accomplished by co-operating with the manufacturers. It was agreed to get in touch with the Canadian Manufacturers' Association and offer the services of the engineers in this connection in a consulting capacity or otherwise.

The exhibition of power plant equipment and supplies was up to the usual high standard, about twenty-seven firms exhibiting. The sports which were held on Wednesday at Port Stanley passed off successfully and the relaxation was as usual much appreciated. A pleasant evening was spent on Tuesday at Springbank Park, where an excellent supper was served followed by a musical entertainment. There were 60 delegates attending the convention, while about 230 persons went to Port Stanley and 175 to Springbank Park.

Convention Opening

The convention was opened on Tuesday morning at Hymen's Hall by Mayor C. R. Sommerville, with grand president R. F. Gofton in the chair, the mayor being introduced by George E. Moll, a past president of the local branch.

Mayor Sommerville extended a hearty welcome from the council and the citizens of London to the delegates. He hoped that pleasant memories would be with them in the coming year as a result of their visit to this city. He took much pleasure, he said, in promising them, on behalf of the citizens, the freedom of the city.

In a brief address, grand president R. F. Gofton thanked his worship and the council, and the general public of London for the hearty welcome. The city was complimented on its well-kept streets, and the general beauty of its parks and avenues. The strangers present would always maintain a high regard for the hospitality of the "Forest City."

Flight-Lieut. Lloyd Archibald, formerly of Toronto, but, since one year ago, a prisoner of war in Germany, was called upon for a speech. In the unfortunate absence of Lieut. Archibald, who is president of the executive of the Exhibitors' Association, Gordon C. Keith of Toronto addressed the audience. Regrets were expressed at the absence of the member of the Aviation Corps. Tribute was paid to the bravery which he had exhibited over the fields of France. The hope was expressed that his release from Germany would take place in the near future.

On behalf of the local lodge, a cordial welcome was accorded the delegates by W. G. Walters, to which S. Balmfirth of Toronto replied. The efforts which had been put forth by the local members for the entertainment of the visiting delegates were acknowledged by the speaker.

The conservation of coal was handled by F. R. Lowe, Editor of "Power," New York. Many suggestions were presented to the meeting along this line. The question of reciprocity in graded licen-

C.A.S.E. CONVENTION. GROUP OF DELEGATES AT PORT STANLEY.

C.A.S.E. CONVENTION. GROUP OF ENGINEERS, EXHIBITORS AND FRIENDS AT PORT STANLEY.

ses between the provinces of Ontario and Quebec was discussed by Ephraim Valiquet chief engineer of the Montreal water works, and chairman of the Board of Examiners for the Province of Quebec. He expressed the hope that the convention would take some action on the question. He came here at the suggestion of the Minister of Public Works Taschereau, to obtain the co-operation of the C. A. S. E. to this end. He was assured that this would be fully discussed at the meeting on Wednesday night.

A. M. ("Dad") Wickens of Toronto, founder of the C. A. S. E., spoke on organization of the craft in general. A resume of the growth of the organization was given. The progress of the engineering trade during the last few years was noted with a pardonable pride by the speaker.

Secretary J. H. Hale of Hamilton outlined the general business, which will come up before the convention, to the delegates.

C. B. Turner, chairman of the entertainment committee of the Exhibitors' Association, gave a hearty invitation to the engineers and their families to attend the picnic held at Port Stanley on Wednesday afternoon.

Tuesday Afternoon Session

A spirited discussion, dealing with the efficient operation of steam electric power plants occupied much of the time of the business on Tuesday. Several resolutions in reference to the question were formed by a committee and were presented to the convention later for approval.

The fuel situation and conservation in relation to electric energy was also discussed. An effort will be made to secure closer co-operation between the Canadian Manufacturers' Association and the C. A. S. E., with a view to the saving of fuel. A resolution was passed urging that the manufacturers who have electric generating plants, and who have some power to spare, offer their surplus energy to the central stations, where the proper connections can be readily made. A copy of this resolution will be sent to the Dominion Fuel Controller and to all members of the Manufacturers' Association. It was thought that this action would have a tendency to save coal this winter in the steam-operated central stations.

Graded Certificates

Graded certificates for engineers were practically indorsed by the convention. This opens the way for reciprocity in engineers between the several provinces of the Dominion.

The following committees were appointed: Credential — A. Clements, Hamilton; G. F. Galloway, London; M. J. Flood, Owen Sound. Mileage and per diem—D. Laver, Hamilton; W. Corham, Belleville; A. M. Wickens, Toronto. Good of the order—W. Greenless, Montreal; W. G. Walters, London; J. Brown, Toronto; A. D. Ross, Montreal; Charles Berry, Ottawa. Ways and means—F. Harper, Kingston; J. J. Heckman, Stratford; D. L. Webster, Bradford; J. McCaffery, Sudbury; W. Cougdon, Chatham; A. R. Taylor, Toronto. Auditors—I. J. Tait, Montreal; C. Ott, Kitchener; S. E. Cosford, Hamilton.

The financial statement, which was presented by treasurer A. W. Heath, of Hamilton, was very encouraging, and showed a good balance on hand.

New Lodges Proposed

Communications asking that lodges be established in the respective centres were received from Drumhella, Alta.; Leamington, Windsor, Sarnia and Winnipeg. Woodstock and Ingersoll also want a lodge. The organization of these will be proceeded with as soon as possible.

S. E. Wichert, president of the National Association, telegraphed his regrets that he was unable to be present.

F. W. Raven of Chicago, grand lodge secretary, was present and gave a brief address on questions of general interest to the engineers.

Several technical questions were discussed by W. C. McGhie, S. Balmfirth, J. H. Hale, I. J. Tait, A. M. Wickens

Wednesday Morning Session

The session on Wednesday morning opened with a discusion regarding the place for next year's convention, a decision being left over until Thursday.

The proposition to hold the convention biennially, while it had a number of ardent supporters, was turned down by the executive. It was thought that with a meeting every two years, the members would lose interest in the convention. The expense of the annual meeting was thought to be well repaid in the benefits which the individual members received.

Much of the business on Wednesday morning was of a private nature in connection with the various lodges. The meeting adjourned at noon, to meet on Thursday morning.

Concluding Sessions

The session on Thursday morning was devoted to finishing up business left over and the election of officers for the ensuing year. A committee was appointed to work out details in connection with the grading of engineers' certificates. A resolution was also carried appointing a committee to get in touch with the Canadian Manufacturers' Association in connection with conservation of coal. It was unanimously decided to hold the convention next year at Brantford, Ont., to begin on the last Tuesday in June.

A resolution unanimously recommending reciprocity of licenses between the several provinces of the Dominion and the United States, was adopted by the meeting. Copies of the resolution will be sent to the Public Works Department of Ontario.

S. Balmfirth, of Toronto, was chosen to represent the C. A. S. E., at the convention of the N. A. S. E., which is to be held in Cincinnati in September.

Hearty votes of thanks were tendered the Exhibitors' Association for the entertainment at Port Stanley on Wednesday; to the N. A. S. E. for the silk Stars and Stripes which was brought from that body to the C. A. S. E. by secretary F. W. Raven, and to F. W. Raven for his helpful messages to London Local No. 30; Mayor C. R. Somer-

ville, the city council, and the citizens generally for the hospitality shown; the Ladies' Auxiliary, and the press.

Election of C. A. S. E. Officers

The following Grand Lodge officers were elected for the ensuing year: Past president, R. F. Gofton, Kitchener; president, W. M. Cooke, Belleville; 1st vice-president, George E. Moll, London; 2nd vice-president, I. J. Tait, Montreal; 3rd vice-president, Daniel L. Webster, Brantford; secretary, John H. Hale, Hamilton (re-elected); conductor, Charles Berry, Ottawa; door-keeper, A. R. Taylor, Toronto.

A past president's jewel was presented to R. F. Gofton.

All officers were installed in the afternoon by grand installing officer S. E. Cosford, Hamilton and grand tyler F. W. Raven, national secretary of the N. A. S. E., Chicago.

Ladies' Auxiliary

The Ladies' Auxiliary is planning to organize a branch in London among the engineers' wives. A number of applications are already filled out, and it is hoped that a lodge will be started here soon. During their visit to London, the ladies were shown through the factories of the McLary Mfg. Co. and the McCormick Mfg. Co. At both places they were treated to a luncheon by the respective firms.

The Ladies' Auxiliary elected the following officers: Past president, Mrs. W. A. Sweet, Hamilton; President, Mrs. W. G. Blackgrove, Toronto; Vice-president, Mrs. C. W. Fowler, Toronto; Secretary, Mrs. Charles Hooper, Ottawa, Treasurer, Mrs. Edward Grandbois, Chatham; Conductor, Mrs. C. Ott, Kitchener; Doorkeeper, Mrs. A. W. Heath, Hamilton.

Exhibitors' Association Officers

The annual meeting of the Exhibitors' Association was held on Thursday morning with vice-president C. W. Schrag in the chair. The ordinary routine business was disposed of and a message of sympathy was sent to Mrs. Archibald, mother of Flight-Lieut. Lloyd Archibald who is a prisoner of war in Germany. It was agreed to hold the exhibition at Brantford next year, this decision being made after receiving an announcement that the engineers would hold their convention in that city. The officers of the Exhibitors' Association were also elected as follows: Past president Lieut. Lloyd Archibald, Toronto; President, C. N. Schrag, Toronto; 1st vice-pres., James Mock, Montreal; 2nd vice-president, C. B. Turner, Toronto; Treasurer, B. G. Newton, Toronto; Secretary, Gordon C. Keith, Toronto; Assistant secretary, L. H. Rumage, Buffalo; Chairman exhibits committee, A. Betton, Toronto; Chairman reception committee, H. Ramshaw, Hamilton; Chairman entertainment committee, B. Curzon, Montreal.

Entertainment and Addresses

The programme on Wednesday evening in the Exhibition Hall included musical entertainment, distribution of prizes and addresses by Dr. W. A. Riddell, Fred W. Raven, E. F. Valiquet, W. C. McGrie, F. R. Lowe, and a humorous monologue by Jack Armour. During the evening Dr. W. A. Riddell, Fred W. Raven, F. R. Lowe and A. M. Wickens were made honorary members of the C. A. S. E. Grand Lodge. The ceremony was performed on the platform, the obligation being delivered by the retiring grand president, R. F. Gofton, while S. Balmfirth officiated as conductor.

The proceedings opened with the presentation of prizes to the successful contestants at the sports during the afternoon at Port Stanley. Gordon Keith acted as chairman during the evening and performed his duties in a fitting manner. The prizes were presented by C. N. Schrag.

The next item on the programme was the presentation of a handsome case of spoons, knives and forks to Gordon Keith, secretary of Exhibitors' Association in recognition of his services on behalf of the association. The presentation was made by Jack Armour. Mr. Keith in replying thanked the donors for their kindness and intimated that he had filled the position of secretary for nine years. W. C. McGhie, on behalf of the Exhibitors' Association then presented an umbrella to George E. Moll of the London Lodge.

Dr. W. A. Riddell's Address

An important feature of the entertainment was an address by Dr. W. A. Riddell, superintendent of the Trades and Labour Branch of the Ontario Department of Public Works. Dr. Riddell prefaced his remarks by thanking the C. A. S. E. executive for the honor conferred in making him an honorary member of the Grand Lodge. Dr. Riddell then proceeded to give an outline of the history of the Trades and Labour Branch stating the purposes and scope of his department. Reference was made to the employment bureau and its operation in the Province of Ontario. Dr. Riddell stated that a large number of men and women had been placed in positions in factories and on farms. Over 200,000 boys had also been enlisted in the food production campaign. Employment bureaus which have been opened in several cities in the province, have done much to relieve the unemployment situation. The department has also done much towards improving conditions for the employees in various industries and also made investigations in connection with vocational work for boys.

Dr. Riddell's memorandum covering the grading of engineers, certificates read as follows:

Fourth Class Certificate

This Certificate shall be known as a "Fireman's Certificate," and shall be optional on the part of the applicant. This class will include firemen, night watchmen, and other assistants to the engineer. The examination is to be oral, the questions based on the safe handling of steam boilers and feeding apparatus.

Present or Compulsory Certificate

The Certificate which has been known as the "Stationary Engineer's Certificate" since the inauguration of this Board in 1918, shall, after the grading of Certificates, retain its present standard, and it shall be compulsory for all engineers operating stationary steam plants of fifty horse-power or over carrying over 20 pounds steam pressure, to hold this Certificate, irrespective of the Fireman's Certificate which they must obtain before trying this examination, unless they can produce a Certificate of equivalent value issued by another Government Board. The examination is of a purely practical nature.

Second Class Certificate

This Certificate shall be optional and recognized as one grade above the present engineer's Certificate. Examinations are to writen and the questions are to be of a practical and technical nature combined. An applicant for this Certificate must be a holder of the present Stationary Engineer's Certificate issued by this Board, or a Certificate of equivalent value issued by another Government Board.

The holders of the present Certificate may be granted Second Class Certificates providing their experience, standing, character, etc., warrant same; length of experience to be decided on at a later date by the Board.

First Class Certificate

This Certificate shall be optional and one grade above the Second Class Certificate. An applicant for this Certificate must hold a Second Class Certificate issued by this Board, or its equivalent issued by some other Government Board, together with ten years' continuous experience in the handling of steam plants. This Certificate can be obtained by examination only, such examination to be of a highly technical and practical nature.

General Information

On and after the First day of January, 1919, this Board will be open to receive applications for the four grades of Certificates mentioned, and forms for same can be obtained by making application to the office of the Stationary Engineers' Board, 15 Queen's Park, Toronto.

On and after the First day of January, 1920, an applicant for any grade must first obtain the lowest grade, and take all examinations up to the grade they may desire, except they can produce Certificates of equal standard issued by another Government Board.

The present or Compulsory Certificate only will be issued to applicants for a Provisional Certificate.

It is the intention of the Board to have all applicants' forms which have been returned to the Board classified into their respective grades by January 1st, 1920.

A vote of thanks proposed by George E. Moll and seconded by S. Balmfirth, was passed expressing the appreciation of the engineers to Dr. Riddell for his efforts on their behalf.

Fred W. Raven's Address

Fred. W. Raven, of Chicago, secretary of the National Association of Station-

ary Engineers, after being introduced by Gordon Keith addressed the gathering, as follows in part:

"The successful organization is the one where the membership takes enough interest to select the proper men as officers and where the officers realize their duty to the organization by always leaving something of interest at each meeting. Such an organization not only becomes great influence but greater in its usefulness to its members and the community. Try and obtain only those men as members who have ambitions and are willing to attend meetings and take part in the work and discussions. Watch closely those who like an active interest and are willing to do something for the other fellow once in a while, these are the men to advance.

"Officers cannot be too careful in the selection of men on committee, some are more or less adapted for certain work and from such selection comes results. The principal committees outside of the educational, are the employment and sick visitation committees."

Mr. Raven in referring to the conservation of fuel said that there is plenty of coal for everybody in the world. There is enough known to last the world over 1,000 years, but most of it is in the ground and mighty little above. Last winter we had many cold days and fuel was scarce, and it will be scarcer this winter. There needs to be 2,500,000 tons of coal mined every day to fully supply our wants. Statistics show that less than 2,500,000 tons are mined each day. There are approximately 600,000,000 tons of coal mined each year, a third of which are used by the railroads.

"Now it is up to you and me, as engineers, to conserve all the coal we possibly can. We are the men that our governments are looking to and expect much from. Our work as engineers means much these days." Mr. Raven referred to the educational value of conventions and the assistance which is being offered by the Boards of Trade and Chambers of Commerce etc., to induce manufacturers to settle in their respective cities. The advantage of fuel and rail facilities were cited as being valuable in the attainment of success but it also required men with brains and capital, men with courage to invest and produce to make success complete. Mr. Raven spoke of the advantages of good feeling between the employer and the worker, and also of the benefits obtained by having pleasant surroundings in the home and in the factory, such conditions tending to produce a healthy and satisfied community which will bring forth the best type of citizenship.

In connection with the work of engineers' organization Mr. Raven stated that the principal duties of organizations of our character is to educate our membership in the arts and sciences of steam engineering and its allied branches and so develop them as to produce for our profession the finished operator who can go to any city and handle any class of machinery now known to produce heat, light and power at the least possible cost, with that great end in view of saving as much as is possible of our national resources for the generations that follow us. Engineers, license laws are very necessary so as to divide engineers from the so-called engineers. It is therefore one of our greatest duties to devise ways and means to put on our statute books laws that will provide for the examination of men who aspire to be called engineers.

"The fact that to-day we are living in the midst of a brilliant civilization and thus made possible largely by the operating engineer. This organization has done its share in past years and hopes to do greater in the future."

"Ambition, inspiration and knowledge travel together and this organization is striving to bring forth these results. Let each and every one aid one another to make life worth living by pratising true fraternalism and so make this old world a better place to live in. And so it is only by fairness between man and man that we can be successful, remembering that "to arbitrate is wisdom" and "to earn more you must learn more."

Mr. Raven at the conclusion of his address presented the C.A.S.E. executive with a silk American flag, for which act of courtesy Bro. E. R. Grofton returned thanks on behalf of the engineers.

Message From Quebec

E. F. Valiquet of Montreal member of the Stationary Engineers Examining Bureau of Quebec, tendered a message of good will from the engineers in Quebec provinces and referred to the advantages which had followed the grading of certificates in the Province of Quebec. Mr. Valiquet's address was very interesting and was well received.

Engineer's Board Activities

The next speaker W. C. McGhie, chairman of the Engineers Board for Ontario gave an interesting review covering the work of the board since its inception ten years ago and also explained how the Stationary Engineers Act explained the method of gathering information from all sources and using the data as a groundwork for drawing up the new act for grading certificates. Various authorities were consulted in order to obtain the views of the various interests concerned. Mr. McGhie stated that conditions at present owing to the war, did not warrant compulsory grading of certificates but expressed the opinion that ultimately this would be adopted. Mr. McGhie asked the engineers to support the Board in framing the new act, because he wanted it to be the best act in America.

F. R. Lowe, of New York, editor of "Power," spoke on the efforts which are being made in the United States in the prosecution of the war, intimating that 1475 steam boilers had been shipped to France to General Pershing. Mr. Lowe spoke at length on the conservation of coal and also on boiler inspection as it affects the community.

At this stage of the proceedings Jack Armour was called upon to offer a vote of thanks to the C. A. S. E. London Lodge for their hospitality and concluded with a humorous monologue which was much enjoyed.

During the evening a musical entertainment was rendered by Mac's orchestra and songs by Earl Hetherington.

Sports at Port Stanley

On Tuesday the engineers, exhibitors and their friends spent a most enjoyable evening at Springbank Park. About 170 sat down to an excellent lunch which was followed by a musical programme, furnished by the McClary orchestra. The following were responsible for the arrangements: George Moll, chairman; W. Walters, D. F. Campbell and D. Freedy. J. Armour of New York in a humorous speech, gave an account of a "colored" wedding.

A most enjoyable afternoon, favored by fine weather, was spent at Port Stanley on Wednesday where a good programme of sports was carried out. The programme was put on by the Exhibitors Association and the guests numbered 230. A special train of six cars on the London and Port Stanley Railway was required to carry the crowd to the Port. What was described as one of the fastest and one of the most scientific games of baseball was played by teams picked from the engineers and the supply men. The score at the end of the fifth inning, when the last call was made for supper, was 14-10, in favor of the engineers. W. G. Walters captained the engineers and L. F. Mayne led the supply men to a near-victory. The pitchers were L. F. Mayne and George F. Galloway, and the catchers were John Middleton and Geo. Ayrscott.

In the young ladies' race Agnes England led, with Kathleen England and Florence Galloway tying for second place. Mrs. D. R. Laver and Mrs. Dan Freedy demonstrated their speed in the potato race, winning first and second among a number of competitors.

The fat ladies' race was won by Mrs. S. Nash and Mrs. A Clements.

Mrs. D. Freedy with John Whittaker and Mr. and Mrs. D. Laver won the prizes in the thread-and-needle race by a small margin.

In the boot and shoe race G. F. Galloway led, with S. Balmfirth next.

John Whittaker and S. Balmfirth crossed the line ahead of the rest of the fat men.

In the "over 40" class W. L. Roadhouse and John Agroff carried off the honors.

The biscuit-eating contest was won by Mrs. William Middleton and Mrs. D. R. Laver.

G. F. Galloway with J. Whittaker, and C. N. Schrag with S. Balmfirth, after numerous tumbles, headed the list in the wheelbarrow race.

Mrs. D. Laver and Mrs. S. Nash for the ladies, and J. Thompson and C. N. Schrag for the men, displayed their ability in picking clothespins off a line with their teeth and beat all other competitors easily.

J. Williams of Quelph was the oldest engineer on the grounds who is actively

engaged in the operation of a steam plant.

The prize for the largest family was not awarded. Apparently engineers have no families. At any rate, several who intended trying for this prize could not gather their children together at the time of the judging.

C. B. Turner and George E. Moll were the judges, while Earl Hetherington and C. W. Schrag also officiated in a similar capacity. A photograph was taken of the entire party and also of the delegates. After a war luncheon served in the cafeteria, the party left for London in special cars.

Exhibitors, Representatives and Exhibits

Allen General Supplies Ltd., Toronto. E. D. Wilkes, Venturi meters and regulators. Dwight Co., indicator. Eclipse steam specialties.

Geo. W. Cole, Ltd., Toronto.—W. H. Rose and J. E. Farrell, Cole boiler feed trap. Cole check valve.

V. D. Anderson Co., Cleveland.—L. H. Rumage, Steam traps and other power specialties.

Canadian Fairbanks-Morse Co., Toronto and London.— Fred Evans and M. J. Kane of Toronto and R. V. Donaldson of London, Durablo sheet packing, Palmetto packings, Farnsworth Vacuum trap, steam specialties.

Crane Packing Co., Toronto.— R. R. Grant and J. E. Ayrscott, Metallic packing for all purposes.

Darling Bros., Montreal.—E. B. Curzon, Reliance marine reducing valve. Dexter reseating machine. Clarke flexible coupling. Syphon and steam traps. Duplex pump etc.

Deaborn Chemical Co., Toronto.—T. Beebe and J. Thompson. Deaborn boiler feed and water treatment.

Canadian Manufacturer, Toronto.—Gordon C. Keith.

Dunlop Tire & Rubber Co., Toronto.—Packings and mechanical rubber goods.

Dart Union Co., Toronto.—Dart Unions.

Equipment Specialties, Ltd., Toronto.—C. W. Schrag. Literature covering valves and centrifugal pumps, etc.

Empire Mfg. Co., London.—L. F. Mayne. Valves, cocks and brass goods.

The R. Bigley Mfg. Co., Toronto.—E. A. Wilkinson. Lunkenheimer steam specialties, valves, etc.

Garlock Packing Co., Hamilton.—R. A. Lyons and H. J. Ramshaw. Garlock packings, gaskets and pump valves, etc.

France Packing Co., Tacony, Pa.—A. F. France and A. W. France. Metallic packings for marine and stationary service.

Goldie & McCulloch Co., Galt.—Earl F. Hetherington. Photographs and literature descriptive of engine and boiler installations and the "Roturbo" pump.

Green's Economizer Ltd., Toronto.—C. W. Worthington, T. J. Tait. G. C. Usher and T. F. Daggett. Green's fuel economizer, Uehling Co., recorder. "Roto" tube. cleaner. Type "E" underfeed stoker. Custodis radial brick chimneys.

John W. Gates, Montreal.—John W. Gates. Patent Boiler settings and fire brick arch.

International Chemical Co., Toronto.—J. M. Allen. Betson's plastic fire brick. "Protecto" treatment for boiler feed water. "Protectocoat" for concrete. Protecto belt preservative, etc.

James Morrison Brass Mfg. Co., Toronto.—A. Betton and J. Noble—Display of brass goods, valves, lubricators, whistles, injectors, gauges, etc.

National Boiler Seam Protector Co., Toronto.—W. E. Holder. Garth boiler seam protector and blow-off pipe protector.

E. Leonard & Sons, London.—Engines and boilers.

Mason Regulator & Engineering Co. Montreal.—E. T. Jeffrey, W. R. Kay and H. L. Peiler.—Bundy traps and oil separators, Coppus blowers, Stratton steam separators, Everlasting blow off valve, Ashton steam specialties. Mason valves and regulators, etc.

Jenkins Bros., Montreal.—T. S. Mock—Valves and packing.

Mueller Mfg. Co., Sarnia.—F. F. Heximer.—Regulating, reducing and relief valves, fan engine regulating valves, strainers, globe valves, steam cocks and pipe end reamers, etc.

Power, House, Toronto.—A. G. Webster, A. J. Tallman.

Power.—New York. F. R. Lowe and J. Armour.

Quaker City Rubber Co., Philadelphia.—G. M. Wilkinson-Daniels, P.P.P. rod packing. Ebonite sheet and stop valve packing. Full line of high grade mechanical rubber goods.

Thompson-Gordon Ltd., Hamilton. E. Gordon. Packings.

London Engine Supply Co., London. Packings.

C. B. Turner, Montreal.—C. B. Turner. Plastic boiler lining. Myers boiler cleaner.

W. R. Sexton Boiler Setting Co., Toronto. W. R. Sexton. "Nonpareil" shaking grates.

THE DECAY OF METALS

By decay of metals is meant changes of an unfavorable character that take place when in use or in storage, especially those that proceed completely through the mass of the metal. The simplest of these is the disintegration due to molecular change of the kind known in chemistry as allotropic. This is especially observable in tin, which becomes unstable at 644 degrees F. and may gradually change from a tough white metal into a gray powder. This condition is first manifested as small spots at which mounds of gray powder soon appear. In a short time, each spot becomes a hole, which rapidly perforates the metal. A peculiarity of this trouble is that it rapidly spreads from one place to another, like an infectious disease; it is therefore known as the "tin plague." In cold countries like Russia, the tin roofs of the affected areas are quickly destroyed when the process of decay is started. It seems as though the powder must be carried by the wind, and that wherever it settles it starts the tin decaying. Tin is also likely to undergo a molecular change at the temperature of boiling water. This is shown by the columnar structure that is frequently found in pieces of broken condenser worms. Allotropic changes occur also in lead, especially lead sheets subjected to the application of solutions containing lead salts. This change does not appear to be connected with the impurities in ordinary lead, as it seems to occur as readily with common sheet lead and the purest assay foil.

Decay may also be due to the movement of gases dissolved in a metal. This is the cause of the brittleness of nickel wires used as resistances in electric furnaces. The heating of the wire sets free the dissolved gases invariably contained in nickel. As the cooling between two periods of use is too rapid for a complete reversal of the process, a part of the gas remains undissolved between the grains of metal. As this alternate heating and cooling continues, the grains separate and the wire crumbles.

PERSONAL

J. M. Wilson has resigned as editor in chief of POWER HOUSE and allied publications of the MacLean Publishing Co., Ltd., Toronto, to accept a position on the engineering staff of the Standard Parts Co., Inc., Cleveland, O.

The death occurred at Hamilton on Monday, June 24, of John Howard Kerr, secretary of the Canadian Westinghouse Co. The funeral took place in Pittsburg. Mr. Kerr was well known to the electrical and machinery trade in this country.

S. A. Armstrong, deputy minister of the Soldiers' Re-establishment Commission, it is understood, has been offered the position of general manager of the Jones Underfeed Stoker Co., of Chicago. The Chicago position is rated at $25,000 per annum.

J. S. Donal has been temporarily assigned as manager to the Canadian Bond Hanger and Coupling Company, Alexandria, Ont., from one of the associated companies in the United States. R. J. Rose, who was the former manager, is now with the Newport News Shipbuilding Company, Newport News, Va.

Alfred C. Roelfson, vice-president and works manager of the Roelfson Machine Co., Galt, Ont., was married on Saturday, June 15th, to Miss Alberta McBride of Galt, daughter of William McBride, of the safe and vault department of the Goldie & McCulloch Co., Galt. After the ceremony the newly married couple left for New York and Boston.

THERE is an item of expense, in the way of lost heat units, in blowing down a boiler; hence, undue liberality in the operation is to be avoided.

The Operators' Point of View

EXHAUST STEAM vs. LIVE STEAM

MR. BALMFIRTH'S experience with live steam for heating is not an isolated one.

In a district steam heating plant not far from here it was common practice some years ago to run engines with a friction load in order to get exhaust steam for heating in preference to live steam.

The exhaust from an engine running with a friction load must be superheated unless the boiler pressure is very low.

It is therefore in the same condition as the steam which has passed through a reducing valve except that its superheat is not so great, due to the heat required for the friction load and the greater loss through radiation from the cylinder, pipes, etc.

There is not much doubt that the exhaust from Mr. Balmfirth's engines was superheated, as they had no load. I hardly thing that Mr. Balmfirth's explanation is correct.

If it were correct, then a pressure gauge installed at the extreme end of the heating system would show a lower pressure with live steam than with exhaust, which is not probable.

If there was actually more live steam than of exhaust, admitted to the heating system, then there must have been more heat units, and those heat units must have been dissipated before the steam would be condensed. There must, therefore, have been some pretty busy radiators in the area heated, namely, the middle of the lower floor.

As we have no evidence that more steam was admitted, and none that the reducing valve was of sufficient capacity, it leaves an opening for me to make a guess, which is that the pulsations of the engines prevented the bubbles of steam from sticking to the boiler surface and so reducing the efficiency of the boilers.

If Mr. Balmfirth would reepat the experiment and find out if more live steam was used, it might enlighten us, and, perhaps, then another guess would be in order.

St. Catharines. R. McLaren.

CALCULATING THE ECONOMY OF BOILER FEED TRAPS

THE writer has frequently heard discussions regarding the difference in economy of boiler feeding by direct acting boiler feed pumps compared with direct return boiler feed traps, but has never yet met anyone who has actually calculated the savings in favor of feed traps. In view of the wide claims which are made by all trap makers, the writer decided to figure for himself taking for example the feeding of a 100-horse-power boiler at 100 pounds pressure.

The example is based on the pump using 150 pounds of steam per horse-power hour delivered (Babcock on steam) gives very much higher steam consumption.

100 h.p. x 30 equals 3,000 pounds of water per hour, or 50 pounds per minute. 100 pounds pressure equals 230 feet head (approx.).

50 pounds x 230 feet equals 11,500 feet pounds to move the water (actual). Add for friction in pipes and valves, elbows, etc., 25 per cent. additional, 2,900; Add for slipping and losses, 25 per cent. additional, 2,900; total feet pounds of work, 17,300; total feet pounds, 17,300; 33,000 equals ½ h.p.

150 pounds of steam x .5 equals 75 pounds of steam required to do the work.

Steam used per hour to feed boiler by pump, say 75 pounds; 30 pounds of water evaporated, being 1 h.p. (75/30 pounds). This equals 2½ h.p. or 2½ per cent. of the boiler power required to operate the pump. This figure is very conservative, as average tests show about 4-5 per cent.

Feeding the same boiler with a boiler feed trap, using condensation, which returns at say 50 pounds pressure and 300° F. temp., as boiler feed water.

As before, the boiler requires 3,000 pounds of water. This quantity multiplied by 27.7, equals 83,100 cubic inches required per hour for evaporation.

As the trap will operate forty-five times per hour in average practice, it will handle 83100/45 or 1847 cubic inches per operation. For each operation this equals 1.07 cubic feet of water handled by the trap (1847/1728—1.07 c. ft.), and discharged into the boiler.

In practice, this water is displaced by an equal volume of steam admitted to the drum of the trap. The trap is operated under boiler pressure (100 pounds).

After the water is displaced 1.07 cubic feet of steam at 100 pounds pressure remains in the drum. The weight of 1.07 c. feet of steam is .278 pounds (see steam table). Weight of 1 cubic foot at 100 pounds pressure, .26 pound).

As the condensation (or water) is at 50 pounds pressure, the pressure in drum must be reduced to 50 pounds before the water will enter. Some of the steam escapes until the pressure drops to 50 pounds, when there remains in the drum 1.07 cubic feet of steam at 50 pounds pressure. The weight of this volume of steam is .161 pounds (1.07 x .151 (see steam table for this). As the water now enters the trap, this steam which remains is condensed by the water.

The temperature of the water in the drum of the trap is raised by absorbing the heat given up by the steam in condensing to water. The contents are 66.9 pounds of water. The latent heat in the steam at 50 pounds pressure is 904 B. T. U. per pound. There is .161 pounds condensed, containing 145.5 B. T. U. This heat divided by the water contents gives a temperature raise of about 2° F. in the mean temperature of the water, or 6,000 B. T. U. per hour.

The difference between the weight of the original volume at 100 pounds pressure (.278 pounds) and the volume at 50 pounds which is condensed (161) represents the weight of steam which exhausts from the trap at each operation. This amount is .117 pounds of steam.

As the boiler feed trap operates forty-five times per hour, the steam escaping from the trap equals 5.265 pounds of steam per hour in the form of exhaust steam. This represents the amount of steam used to feed the boiler.

With the pump, and boiler feed trap, operating under these conditions, the saving of steam consumed in feeding the boilers is the difference between 75 pounds of steam used by the pump, and 5.26 pounds of steam used by the trap. which is equal to 69.66 pounds of steam which is equal to 69.66 per hour or about 92 per cent. of the steam required by the pump.

The saving of steam in favor of the boiler feed trap operating for ten hours a day is 696 pounds of steam for the same amount of work as developed by the pump.

When steam at 100 pounds is admitted to contact with water in the boiler feed trap at the temperature above 332° F. the steam must superheat the water to approximately the temperature of the steam, before the presure of the boiler is established in the drum of trap. This temperature is about 338° F., and to gain this heat the latent heat of the steam at 100 pounds pressure is given up to the water to the extent of 6° F. to each pound of water, or a total of 401.4 B. T. U., which is the latent heat of rather less than ½ pound of steam

at this pressure. The final temperature of water leaving the boiler feed trap is approximately 8° F. higher than the temperature of the condensate at 50 pounds pressure entering the trap. This is a clear gain, when compared with the boiler feed pump where the water is not affected in temperature.

With a double trap system operating as a boiler feeding apparatus, and using a boiler feed trap above the boiler, and a lifting trap of the "condenser" type below the boiler. The condenser drawing the water from an open heater, and operating under a 50-pound lifting pressure, and about 25 pounds water pressure on the condenser spray. The amount of steam required to feed the boiler would be just about double the above, as the condenser trap would consume about the same as the boiler feed trap, or perhaps slightly less steam.

The total steam consumption for the double trap system would be thus about 10.5 pounds of steam per hour against 75 pounds of steam per hour for the pump. The work would thus be done on 14 per cent. of the steam consumption of the boiler feed pump.

The daily steam consumption for the pump working ten hours is 750 pounds. The daily steam consumption for the double trap system working 10 hours is 105 pounds. The daily steam saving in feeding boiler is 645 pounds.

Assuming the steam is produced at the rate of 8 pounds of steam per pound of coal, the coal saving on feeding the boiler by traps is approximately 80.18 pounds of coal per ten hour a day. The yearly coal saving for 300 days would be twelve tons at least, for each 100 h.p. in the boiler plant by operating an efficient automatic boiler feed apparatus.

From tables prepared by authorities, based on experiment and practice, it has been found that the relative fuel consumption and economies for the different methods of boiler feeding is about as follows: 100 pounds of coal required for pump, feeding cold water taken as standard, or unity.

Boiler Feeding Method	Amount of Fuel Used Lbs.	Saving of fuel over the amount required by pump feeding cold water
Direct acting pump feeding cold water	100	0%
Injector feeding and warming the water, average temp. (150 deg. F)	98	2%
Injector feeding through heater at average temperature (200 deg. F.)	93	7%
Direct acting feed pump feeding through heater	88	12%
Power pump through heater	86	14%
		hot or cold water pump feeding with Over direct acting
Direct return boiler feed traps as before explained	14	86%

Note.—The last figures are the writer's, and based on the previous explanations and his experiences in this line.

Which is the most economical method of boiler feeding?

HEAT-RESISTING PAINTS

By Mark Meredith.

The best heat-resisting paints are made from hardened asphaltum or pitch, dissolved in a fluid solvent; whilst for temperatures below the boiling water, casein, animal albumin and alkali silicates have given good results, writes a German authority. Pyroxylin varnish is very durable, but browns when heated, and can only be used when in admixture with black body colors. The following preparations are worthy of mention.

Roman Prasser's Recipe.—Equal parts (40) of pigment and spirit varnish (compounded of 1 part of bleached shellac in 7 parts of spirit) are intimately mixed with 1 part of camphor and 5 parts of bleached oil varnish. The article to be coated is brushed over several times with a mixture of gypsum and spirit varnish, flatted and painted over with the above preparation, being finally polished lightly with shellac varnish. This paint will stand the heat of boiling water for some time, but browns on prolonged exposure and peels off.

G. M. Neisel's Recipe.—Solid fats or fatty acids are distilled at 250 to 300 deg. C. with superheated steam. The residue being mixed with about 10 per cent. of red lead and 2 per cent. of litharge, treated with superheated steam at 400 to 500 deg. C. and thinned down at 150 to 200 deg. C. to workable consistency with linseed oil. As an alternative method the dilution with linseed oil is replaced by blowing in 25 per cent. of petroleum vapor, and then diluting with the crude benzol or other dilutent when sufficiently cool. The product is said to dry with a glossy surface, and to stand a dry heat of 500 deg. C. or damp heat up to 250 deg. C. As a matter of fact, an asphaltic substance and especially the distillation residues from fats (bone pitch, etc.) are capable of resisting high temperatures, and are used for stoving enamels.

Meyer's Recipe.—Residues from the distillation of fatty acids are heated to about 500 deg. C. with lead oxide and lead peroxide for three to four hours until thoroughly combined, the mass being dissolved in mineral oil and thinned down with turpes.

Bethisy's Recipe.—The mass consists of nitro-cellulose and a solution of calcium chloride in amyl acetate, with an addition of ether, alcohol, alum, talc, asbestos or mica, elasticity being imparted by vaseline oil or lavender. Celluloid varnishes are capable of standing a certain amount of heat.

Selmay Meyer's Recipe.—A heat-resisting varnish for iron ware, especially iron stoves, etc., is prepared by mixing powdered liver of sulphur, cyanide of potash, bicarbonate of soda, and sufficient cassel brown to give the desired color, and the mixture is saturated with alcohol. The pulp is passed through a sieve to remove coarse particles, and after being applied to the metal is exposed to a temperature of 200 to 300 degrees C. Other fireproof pigments may be submitted for the brown. This preparation is an enamel rather than a paint, but will stand heat very well.

Syracuse Tar.—A mixture of finely ground alum, asbestos and borax or boric acid is stirred into melted coal tar, the proportions being 60 to 65 or 40 to 50 parts of tar, 8 to 4 to 2 to 8 of alum, 20 to 5 or 38 to 30 of boric acid, 12 to 5 or 20 to 13 of borax, and 5 to 8 of asbestos. The idea seems to be that the salts will sinter together under the influence of the heat, the tar being presumably carbonized.

Avenarius' Recipe.—Ten parts of alkali silicate are heated under pressure with 25 parts of casein, a pasty mass being formed. This liquid is mixed with 0.2 part of carbonate of magnesia and 0.1 parts of borax, to increase the heat-resisting properties, whereupon 0.15 part of zinc oxide, 0.3 part of sodium phosphate and a suitable quantity of lime and earthly pigment is added to give covering power. For use, the mass is thinned with boiling water, and is said to stand a temperature of 100 deg. C. (212 deg. F.).

Fairweather's Recipe.—Equal parts of silicon carbide and semi-fluid alkali silicate are mixed together, 3 to 10 per cent. of chalk being added.

Hall's Fireproof Recipe.—This paint consists of moist silicate of magnesia, 5½ of dextrin, 5½ of gypsum, 2 of chalk, 2 of alum, and 1 of common salt. Four parts of this powder are mixed with three of boiling water for use. This preparation and the preceding one owe their "fire-resisting" properties to the sintering of the salts when heated.

Eymer's fireproof varnish is compounded of a mixture of alkali silicates with asbestos or other fireproof material and vegetable or mineral oils, or oily substances like glycerine.

Give a couple of coats of a good washable distemper, upon which should be given two coats of oil paint, the first somewhat flat and the last with a little oak varnish added to it. Painting on galvanized iron is at all times difficult, and there are various preparations on the market specially made for the purpose. If you do not care for the water paint plan try the following:—First go over the work with a wire brush so as to roughen the surface, then apply a coat of red lead well brushed out and mixed thin with boiled oil and turpentine. You will, of course, only mix just sufficient quantity of the red lead for the job, and will take care to stir from time to time while in use, as the red lead sets quickly. If there is much of the work to be done, we should recommend you to use orange lead instead of red lead, as although the two are practically of the same nature, the orange lead is a good deal lighter, and hence does not settle so quickly. You may take it that everything despends on the priming coat, and if this is satisfactory, the two or three coats upon it will hold well. The washable distemper in our experience gives as good a result as anything, and is much cheaper than the red lead system.

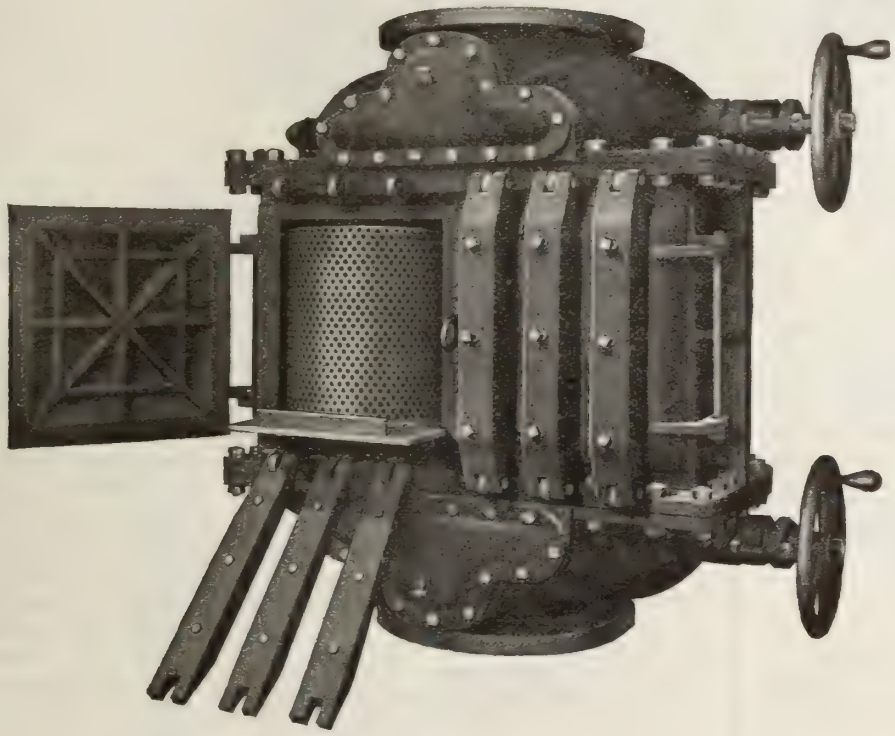
TWIN STRAINERS

eliminate clogging of pumps, condensers and other water-handling machinery



A TWIN STRAINER can't be clogged up, for when one basket is fouled with any sort of solid matter, a clean basket is put into service by simply moving two valves. The dirty basket can then be lifted out, carried to a convenient place, cleaned and then replaced in the Strainer—all this without interrupting the flow for an instant.

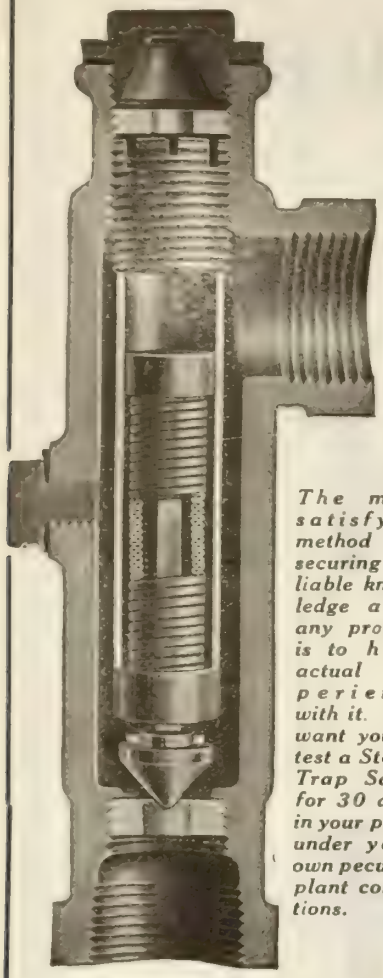
Full particulars in Bulletin "A," which will be sent on request

ELLIOTT COMPANY

435 GRANT STREET - PITTSBURGH, PA.

If any advertisement interests you, tear it out now and place with letters to be answered.

Knowledge Through Experience



The most satisfying method of securing reliable knowledge about any product is to have actual experience with it. We want you to test a Steam Trap Sarco for 30 days in your plant under your own peculiar plant conditions.

Then you'll fully understand the Sarco principle. It is a steam trap deriving its hydraulic impelling force through the expansion and contraction of oil in a hermetically sealed tube contained within the trap.

Then, too, you'll appreciate the small size and large capacity of the Sarco.

You'll understand why it fits anywhere without extra building up or pit digging.

Compared in service, size and price you will know without a trace of doubt that the Steam Trap Sarco is the best "buy" in the market to-day.

Don't forget that it is as good on high pressure as on low pressure.

Special literature sent upon request for folder J-6.

TRADE GOSSIP

Ontario incorporation is granted the Elgin Mfg. Co., to manufacture and trade in all lines of machinery, locomotives, tractors, etc. Capital is $250,000, with head office at London. Directors are: E. G. Yeates, R. C. Macknight, E. D. Parke, D. D. Lethbridge and J. E. Macdougall.

Short of Power.—The rationing of power had to be resorted to again at Galt on account of there being insufficient Hydro to meet the local demands. One circuit was cut out one day and another the following day. Local officials say the rationing may have to continue for several days.

The Canadian S. K. F. Company Ltd., 47 King Street West, Toronto, is now carrying a stock of chrome alloy steel balls in all sizes ready for immediate shipment. These balls, which are hardened clear through, are suitable for the highest class of work and heavy service. They are guaranteed round and true to size within one-ten-thousandth of an inch.

Fuel Economy in the Operation of Hand-Fired Power Plants.—The scarcity of coal last winter and the recent warnings of the fuel administration regarding the possibility of a shortage next winter emphasize the need for greater economy in the use of fuel. The present high rate of production is still insufficient to supply all needs and there seems to be no possibility of an increase in the output of the mines to meet demands.

Ontario incorporation is granted to the Salisbury Electrical Co., Ltd., with capital at $100,000, to carry on the business of electricians, mechanical engineers, manufacturers of and dealers in apparatus for the generation, distribution, supply, acceleration and employment of electricity, electrical supplies and appliances of all kinds, etc. Directors G. E. McCann, J. A. Hammond, A. F. Ball, D. M. Culverwell, G. M. Speers. Head office Toronto.

Dominion incorporation is granted to J. D. C. Forsyth. E. W. Clement, W. P. Clement, R. M. Fisher, E. B. Clemens, Kitchener, under name of John Forsyth, Ltd., to carry on the business of electricians, mechanical engineers, manufacfacturers, workers and dealers in engines, rynamoes, generators, batteries, storage batteries, switch boards, electric lighting plants, electric power plants, electric appliances and accessories of every description, electricity, etc. Capital is $300,000, and head office at Kitchener, Ont.

Change of Address.—Announcement is made of change in address of the Crane Packing Company's New York office to larger quarters in the Park Row Building, and the appointment of Julian N. Walton, manager. A. W. Payne, connected for some time as manager of this district, has been made sales manager of the United States and Canada, with headquarters at the home office in Chicago. The Pittsburgh offices are located in the May Building, Pittsburgh. The Philadelphia office in the Colonial Trust Building.

Calgary.—The coal investigators from Winnipeg have not been satisfied with what they found out about Alberta coal. One of them, J. J. Wallace, makes this statement: "We came here with open mind, and we have made a sincere effort to get at the actual cost of production of a ton of coal, but have been unable to do so. The mine owners would not show us their accounts and give us actual facts. They seemed to prefer not to send any coal to Winnipeg rather than cut the price in any respect. They all say they are paying no dividends, and some even say they are losing money."

Hamilton.—At a meeting of the Hamilton Board of Control tenders were accepted for the construction and installation of the boilers for the beach pumping station. The total cost will be $17,759, which is the lowest tender, and is that of the Goldie-McCullough Company, of Galt. This tender was $10,800 lower than the next lowest. Had the Babcock-Wilcox firm been able to carry out its contract, the cost to the city would have been but $186 lower. The Imperial government stepped in and refused to allow the use of material to construct the boilers in Scotland, with the result that the contract was canceled some months ago. The cost of the boilers was placed at $12,991, according to the tender, the balance being the cost of installation.

Chatham.—A big mass meeting was held in Tecumseh Park late on Saturday afternoon at which the gas problem was discussed. Factories in the city shut down at 5 o'clock because the men walked out to attend the meeting. A resolution just passed by the Mechanic's Board of Trade was brought before the meeting, and unanimously adopted and endorsed, disapproving of the action of the Ontario Railway and Municipal Board in ordering gas shut off in factories and other industrial places, and in thus threatening a bread shortage, with a loss to the bakers in materials, and also stopping the cars of the C., W. & L. E., affecting shipping of stock and interfering wih passenger traffic. The resolution objects to the power given to the Railway Board, objects to the fact that there is no appeal from any action or order of the Board, protests against agreements made in good faith with the city of Chatham being broken, declares that it is contrary to British principles of justice to allow agreements to be set aside, to grant no right of appeals against a Board, and to refuse compensation for losses sustained through an order of the Board.

Had Busy Year.—Much interest is centered in Kingston in the coming financial statement of the Canadian Locomotive Company, which concluded its fiscal year on June 30th. The auditors are working on the figures, and the report will be made public property before a great length of time. The company's plants have been kept very busy throughout the accounting period, and orders on the books are said to be sufficient to keep them work-

ing to capacity for a considerable time ahead. Work is proceeding satisfactorily on the Government contracts calling for locomotives, and the outlook is considered to be bright for the coming fiscal year. For the year ending June 30th, 1917, record earnings were shown, manufacturing profits amounting to $721,254 against $57 in 1916, and net profits of $616,254, after payment of bond interests and sinking fund allotments, was equivalent to more than 7.6 per cent. on the combined preferred and common capital or over 25 per cent. on the common stock, after payment of preferred dividends.

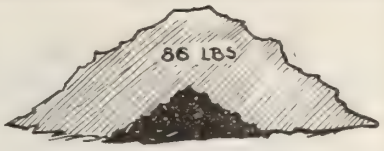
CATALOGUES

Electrical Equipment.— The Ward Leonard Electrical Co., Mount Vernon, N.Y., has issued a pocket size loose leaf bulletin covering an interesting line of electrical equipment such as rheostats, controllers, resistance units, etc. The bulletin contains temporary price and data sheets covering only the apparatus upon which the company can offer reliable delivery dates and assure maintenance of prices. The reason being that the company's facilities are now largely devoted to Government work affecting regular production in the meantime.

The Canadian S K F Company, Ltd., 47 King Street West, Toronto, has made arrangements with the Hess-Bright Mfg. Co., Philadelphia, to be Canadian distributors for the well-known Hess-Bright ball bearings. A large stock in all sizes will be carried in Toronto and engineering designs and recommendations will be given for all classes of applications. The Hess-Bright Mfg. Co. control the Conrad patents under which other firms manufacture under license. The Conrad Patent is a method of assembly which enables a ball bearing to be made with continuous raceways, eliminating the necessity of filling sloths which rob the bearing of end thrust capacity. The "Monarch" series of bearings, of the deep groove type, are also made by the Hess-Bright Mfg. Co. These bearings are used extensively in work where heavy end thrusts are encountered such as in airplane propellers, etc.

The Present Day Applications of Ball Bearings is the title of an interesting bulletin being distributed by the Canadian S F K Co., Toronto, principally among colleges and larger educational institutions. This bulletin is gotten up in the form of an illustrated lecture and the company has prepared sets of lantern slides to accompany the lecture for the purpose of creating interest in one of the latest developments in mechanical appliances and showing the latest applications of ball bearings. The lectures and slides are sent out to universities and colleges for the benefit of the students and others who may be interested in mechanical matters. In addition to illustrating and describing the various applications, the bulletin also contains a brief history tracing the development of ball bearings. It deals with the principal features in the design and construction of the S K F ball bearing and

Study The Piles



Seven Times the Power for the Same Coal

The first pile represents coal used making steam to feed boiler using direct steam pump.

The black part of the second pile shows the relative amount of coal necessary to do the work with a Cole Return Trap.

In other words, you get seven times the power for the same coal—or 86% of the fuel saved.

If you want further proof get our latest folder on boiler feeding—No. 9.

GRAPHITE FOR LUBRICATION

Lubrication is a matter of vital importance, yet is apt to be overlooked until something happens. If oil or grease alone are used and the supply unexpectedly fails the resulting damage and trouble will be serious.

DIXON'S FLAKE GRAPHITE

added to oil or grease increases their lubricating value and makes as near a perfect lubricant as is possible. Graphite supplies those qualities that oils lack—endurance and indifference to temperature. Flake Graphite also provides a smooth durable veneer over wearing surfaces that prevents metal-to-metal contact. Write for Booklet No. 222-C.

BOILERS FOR IMMEDIATE SALE

Suitable for shipyards, munition works, mines, [illegible] electric power stations, etc.

5450 H.P. of B. & W. Stationary Boilers

with forged steel headers, and superheaters, [illegible]

2—450 H.P. Boilers, 36 wide, 12 high; 2 48" drums each; installed 1902.

3—660 H.P. Boilers, 21 wide, 14 high; 3 42" drums each; installed 1905.

3—330 H.P. Boilers, 16 wide, 12 high; 2 42" drums each; installed 1910.

1—580 H.P. Boiler, 24 wide, 12 high; 3 42" drums installed 1910.

2—615 H.P. Boilers, 21 wide, 12 high; 3 42" drums each; installed 1910.

8 of these 12 Boilers are now allowed 150 pounds steam and 3 are allowed 135 pounds. All are in operative condition.

If it is desired to add to the capacity of any modern boiler plant carrying 200 pounds pressure for supplying steam turbines, these Boilers can be easily altered to 200 pounds pressure by being fitted with new drums.

For sale as they now stand, including grates and the usual boiler connections and fittings attached to them. Purchaser to make his own inspection, to have access to all available records in owner's possession, and to remove Boilers at his own expense.

In order that possession of any or all of these Boilers is desired, time will be saved by Purchaser sending his representative here without delay.

Correspondence desired only with parties who have immediate use for any or all of the Boilers.

Upright closed type feed water heaters and [illegible] belonging to this plant are also for sale.

WANTED.

WANTED — FIRST-CLASS STATIONARY ENgineer capable of assuming full charge of boiler and engine department of large manufacturing plant in Western Ontario city. Apply stating qualifications and salary expected to Box 452, Power House. (p7h)

FOR SALE

FOR SALE CHEAP—ONE 30 K.W. GENERAtor Set 220 Volt D.C. Ideal Engine—Westinghouse Generator on sub-base—Switchboard; one 20 K.W. Generator Set on sub-base, same as above. These two sets are in perfect condition and we offer decided bargain for quick sale. Winnipeg Machinery Exchange, Sutherland and Gladstone Sts., Winnipeg.

Engines For Sale

1—Allis Tandem Compound, 18 x 32 x 46, 70-75 R.P.M. 350 to 400 H.P. 20' x 38" belt wheel. Run condensing with surface condenser.

1—Goldie & McCulloch, Wheelock Cross Compound Engine, 13 x 23 x 30. Run condensing or non-condensing. 110 R.P.M. 200 H.P. at 90 lbs. steam. Wheel 15' x 20"

1—Brown Corliss L.H. Crank Engine, Simple 12 x 30. 8' x 8" Fly Wheel 100 R.P.M. 80 H.P. at 90 lbs. steam.

1—Inglis Simple Corliss Valve, L.H. Crank Engine, 13" x 30". 12' x 15' belt wheel. 100 R.P.M. 93 H.P. at 90 lbs. steam arranged for condensing with surface condenser

1—Skinner 8" x 12" Center Crank, 60" x 8" belt wheel 150 R.P.M. 15 H.P. at 60 lbs. steam.

1—Robb Armstrong Highspeed Engine, 8½" x 8", Class B Automatic Center Crank, 36" x 8" belt wheel. 350 R.P.M. 42 H.P. at 100 lbs. steam.

All above engines discarded owing adoption electric power. All are in good operating condition and suitable for higher pressures than those mentioned.

We also have a number of large pulleys; several 100 x 125 H.P. Boilers suitable for 90 lbs. pressure.

Ogilvie Flour Mills Co., Ltd.

MOTORS for SALE

1—75 H.P Can. Westinghouse Induction Motor, 550 volts, 3 ph. 60 cy. 900 R.P.M. Complete, rebuilt.

1—100 H.P. Westinghouse, 550 volts, 3 ph., 60 cycle, 1200 R.P.M. Rebuilt.

4—30 H.P. Fairbanks Motors, 550 volts, 3 ph., 60 cy., 1200 R.P.M., complete, good as new.

2—3 H.P. Westinghouse Motors, 220 volts, 3 ph., 60 cy., 1700 R.P.M., good as new.

1—5 H.P. Westinghouse Motor, 220 volts, 3 ph., 60 cy., 1700 R.P.M., good as new.

1—2 H.P. Westinghouse Motor, 220 volts, 3 ph., 60 cy., 1700 R.P.M., good as new

1—40 H.P. Gen Electric Motor, 220 volts, 3 ph, 60 cy., 600 R.P.M., slip ring type with controller and resistance starter.

1—15 H.P. Electric Const. Co. D.C. Motor, 500 volts, 850 R.P.M.

1—3.75 D.C. Westinghouse Generator, 125 volts, 1200 R.P.M.

We also have several 220 volt motors from ½ H.P. to 5 H.P. back geared, all in good shape.

KIPP-KELLY-BROWN, Ltd.
151 Bannatyne Ave. E.
Winnipeg, Man.

describes how ball bearings are manufactured. The applications described cover a large number of industries including automobiles, machine tools, textile, tractors, paper making, milling, wood working, etc. Copies of the bulletin may be had on application by any student, mechanic or engineer interested in the subject. For copies apply to the Canadian S K F Co., 47 King Street West, Toronto.

A Study of the Heat Transmission of Building Materials.—An investigation to determine the coefficients of heat transmission of standard building materials for exterior walls has been completed by the Engineering Experiment Station of the University of Illinois under the direction of A. C. Willard, Professor of Heating and Ventilation, and L. C. Lichty, Research Fellow. The tests were conducted according to the so-called "hot-air box" method, the boxes being built of the material to be tested and of such a size as to insure conditions similar to those found in actual practice. The heating was done electrically so that the input of heat could be controlled and accurately measured. The materials tested included various sizes of tile plastered, magnesia board, cork board, wood, concrete, brick, glass with and without an air space, sheet asbestos and asbestos board. The degree to which the transmission coefficients of the various materials are affected by variations in air velocity, by humidity, and by the use of air spaces in wall is discussed, and the results of the tests are given in detail in Bulletin 102 of the Engineering Experiment Station. The publication is illustrated with diagrams and photographs of the apparatus. Copies of Bulletin 102 may be had gratis by addressing the Engineering Experiment Station, Urbana, Illinois.

A BELT should be capable of transmitting from 5 per cent. to 25 per cent. more power than is actually needed, the excess capacity being governed by the type of drive ranging from 5 per cent. for heavy main drives to 25 per cent. for machine belts.

A JAPANESE invention which coats iron or steel with aluminum has been put into successful operation. The metal to be treated is first galvanized, then it is dipped into a bath of molten aluminum at a temperature varying from 1,100 to 1,200 degs. Fahr. To obtain satisfactory results the metal under treatment must be immersed two or three times. It is claimed that the aluminum coating has wonderfully good adhesive properties and will not wear off through abrasion.

Saving Coal In the Heating System

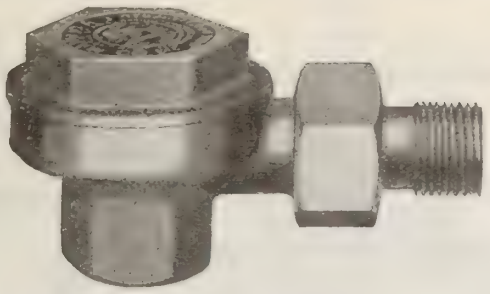
It is entirely possible that the Fuel Controller will enforce the use of electric power. Existing steam plants must then be used only for heating. There will be no more exhaust steam.

Get ready for such conditions by putting your heating system on an economical basis. Heating with live steam is always expensive—and particularly so when the system is inefficient.

The DUNHAM HEATING SERVICE

will enable you to save coal—and get better heat than before—even under such trying conditions. This service is based on the proper control of the radiator and the application of The Dunham Radiator Trap.

Patriotism and economy urge coal saving. Start now! Full details on request.



The Dunham Radiator Trap

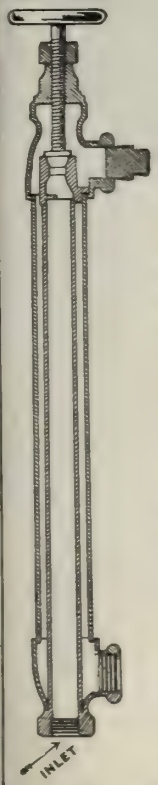
This coal-saving device is the foundation of the Dunham Heating Service. It is attached to the outlet of every radiator.

With the Dunham Radiator Trap you have no broken vacuum due to leaky traps. Superior circulation of steam is easily maintained because all the air and water is automatically eliminated.

Get all the facts!

C. A. Dunham Company, Ltd.
TORONTO, CANADA

Branch Offices:
Halifax Montreal Ottawa Winnipeg Vancouver Calgary



The LONG Patent Steam Trap

Automatically drains jacket kettles, separators and steam mains. Nine hundred to 1,500 feet of one-inch pipe isn't beyond its ability. Also used with splendid success in drying room systems.

Only One Movable Part

Works against 1 and 200 pounds of pressure—no possibility of freezing. Has **two outlets** so it can be installed in any position.

Circular gives full particulars.

Write to-day.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

"Belmont" 1903 Special Hydraulic Packing. For Hot or Cold Water Boiler Feed Pumps (Inside or Outside Packed) and for Hydraulic Work It Has No Equal.

Pressures up to 10,000 lbs.

Cannot Split, Swell or Pinch

We guarantee Belmont Special Hydraulic Packing to give absolute satisfaction under the heaviest pressures, and when exposed to acid or alkaline waters. We know that it is made right, and from the best material, and that "Belmont" is absolutely the "last word" in packing arguments.

JEFFERSON UNIONS

There are many good reasons why you should insist on "JEFFERSONS." In the first place you protect yourself from disappointment and costly shutdowns on account of "doubtful" unions. The name "JEFFERSON" distinguishes the genuine from the "just as good" union. Easily broken promises will not make tight a leaky line or keep superheated steam from sizzling out at the unions.

You cannot afford to take a chance on the unions because the success or failure of the entire line depends upon the class of unions used. The Patented Brass Ring of the "JEFFERSON" is positive insurance against leaks. The "brass-to-iron" joint cannot rust or corrode, so that it's an easy matter to take down a JEFFERSON UNION regardless of how hard it has been set up.

Your jobber has "JEFFERSONS" in stock and he'll be glad to tell you all about them. Ask him if he ever gets a "kick" on a JEFFERSON UNION. Our Catalog "UNIONS" shows all styles and sizes. Write to-day for your copy.

GRATON & KNIGHT

Standardized Series
LEATHER BELTING

Tanned by us for belting use

In times like these you have no right to waste one ounce of power

With all costs shooting skyward, the need of economy is greater every day. Above all, stop power-wastes.

WORN-OUT belts, belts of inferior material—even good belts at the wrong work mean needless waste.

Low first-cost of material doesn't always indicate economy. To us, the largest belt makers in the world, all materials are open for use; but sixty years of experience has impressively convinced us that for power transmission, well-tanned leather is the most durable, efficient, economical belting material. Its natural friction *grip* gives it the maximum *pull* on the pulley.

Careful selection of hides together with scientific tanning and currying processes have given Graton & Knight leather belts the necessary combination of flexibility, firmness, and elasticity to transmit the full power load—*without waste.*

In reality, power economy is simply a matter of using the right belt for every drive. There is a Graton & Knight Standardized Leather Belt for every transmission requirement, a belt scientifically constructed to transmit the utmost power for the longest period of time.

It will *save you money* to let us recommend belts for every drive in your plant. Then, in buying, specify "Graton & Knight—Brand or equal." This does not commit you to buying our belts. It does put your buying on the one economical basis—that of *the work to be done.*

SKF

BALL BEARING HANGERS

(Self-Aligning)

Use More Ball-Bearings and Less Coal

WHAT a fallacy for a manufacturer to spend enough money on his coal pile each year to start a fair-sized bank and yet hesitate to invest the interest on the sum in ball-bearing hangers.

When you consider the number of shaft bearings in the average factory you can readily appreciate the sum a saving of even one dollar per bearing would make in a year.

That many manufacturers are seeing the power problem from this viewpoint is shown by the rapidly increasing demand for S K F Hangers.

Just where do we stand?

CANADIANS are beginning to wonder where we stand with reference to our place in the Empire after the war. Are we to rank as full partners in this grand, big, going concern? Are we to pay our share of the upkeep of the navy? If not, what is to be our status?

Recognizing the growing interest in this problem, the editors of MACLEAN'S decided to devote the July issue to Imperial topics. It offers articles on various phases of our Imperial problem—articles which will have a particular interest at this time when Sir Robert Borden is in London in consultation with the leaders of the Imperial Government.

The July issue contains, besides, a cluster of other big features—readable, fearless and strong. Here are a few of the best:

Field-Marshal Sir Douglas Haig.

Imperial Topics

- "Pocketing Our Imperial Pride" — By H. G. Wells
- "Canada's New Place in the Empire" — By Prof. P. M. Kennedy
- "Living Up to Our Reputation" — By Agnes C. Laut

The War - -

- "Your Old Uncle Sam is Coming Right Back of You" — By Lieut.-Col. J. B. Maclean
- "Stemming the Teuton Tide" — By Geo. Pearson

Fiction - - -

- "The Strange Adventure of the Open Door" - By Arthur Stringer
- "The Three Sapphires" - - By W. A. Fraser
- "The Torby Tragedy" - - By A. C. Allenson
- "The Magic Makers" - - By Alan Sullivan
- "Lennix Ballister—Diplomat" By Archie P. McKishnie

All the regular features as well: Review of Reviews, The Best Books, The Business Outlook, The Investment Situation, Women and Their Work.

July MacLean's

"John Crane" Flexible Metallic Packing is

GOOD FOR EVERY SERVICE

Why bother with a dozen or more different kinds of packings for as many different services when "John Crane" is the only kind you need in your plant? It is equally good for

Steam, Water, Gasoline, Oil, Gas, Air, Ammonia, Vacuum, Acids, Piston Rods, Valve Rods, Plungers, Shafts, Condenser Tubes, Steam Traps, Valve Stems.

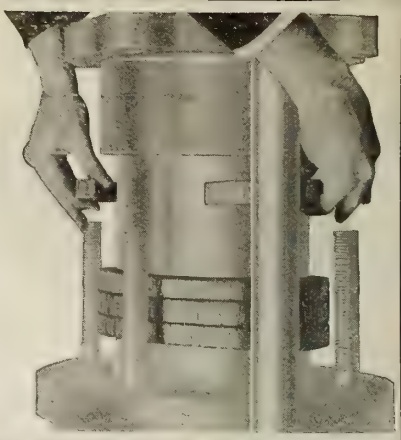
and wherever else packing is needed.

"John Crane" is made of spirally wound layers of smooth babbitt foil, thoroughly saturated with lubricant, making it practically frictionless. Because of its construction it stops every leak, is perfectly flexible, is compressible, conforms easily to the gland and cuts with a pocket knife as easily as fibre

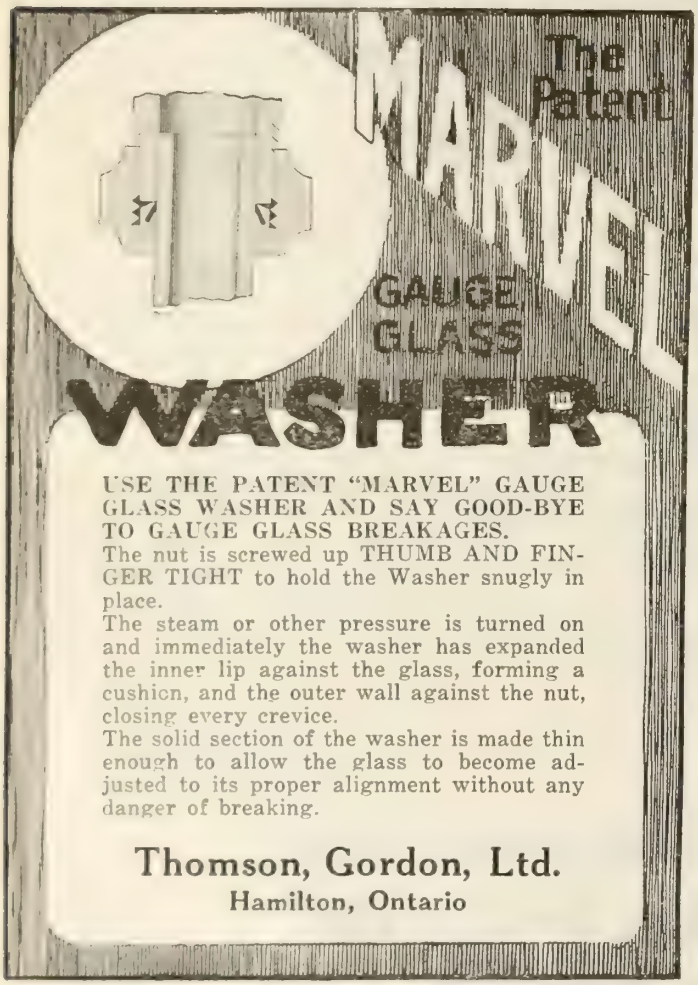
"John Crane" cannot score or cut any rod and lasts for years. If the rod is good in the first place, the packing need never be taken out.

We have a liberal trial offer for those who will give "John Crane" a square deal in trying it out.

Booklet No. 1 tells all about it.



Crane Packing Co. Box 241, Windsor, Ont.—General Office and Factory, Chicago, Ill.



USE THE PATENT "MARVEL" GAUGE GLASS WASHER AND SAY GOOD-BYE TO GAUGE GLASS BREAKAGES.

The nut is screwed up THUMB AND FINGER TIGHT to hold the Washer snugly in place.

The steam or other pressure is turned on and immediately the washer has expanded the inner lip against the glass, forming a cushion, and the outer wall against the nut, closing every crevice.

The solid section of the washer is made thin enough to allow the glass to become adjusted to its proper alignment without any danger of breaking.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID, Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D., Supt. Trades & Labour Branch

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction.* Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically ***eliminates expensive shut-downs.*** Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

"Save the Coal"

You save coal by saving power.

You save power by stopping leaks.

You can stop any kind of pipe-joint leak with a Yarway (formerly Simplex) Pipe-Joint Clamp.

And the leak is stopped instantly—and permanently, if you wish to leave the clamp in place rather than put in a new pipe or joint.

Don't permit costly leaks to sap the energy of your power plant. Let us send you one of these serviceable clamps for 30 days' trial.

When you receive the clamp, put the packing ring on first, follow it with the inner iron ring (see illustration); then bolt on the clamp and tighten the screws. That's all there is to it—simple, but highly effective.

A user writes:

"We had a steam leak on a coupling in an 8-inch steam line which was 30 feet long. The Yarway stopped the leak and prevented our having to take the line down. We also have one of these clamps on an 8-inch hot water line, clamp having been in service for six years and still giving perfect satisfaction."

Write to-day, stating size of line

Johns-Manville
Protective Devices

Dominion of Canada: $12.00 East of Calgary. $12.50 Calgary and West.

Why this extinguisher instead of some other?

THERE might be some excuse for fires if they were hard to prevent, but they are not. Most fires in your stations, sub-stations and other properties start small. You will be adequately protected if a Johns-Manville Fire Extinguisher is in easy reach at every danger point.

But be sure it is a Johns-Manville because then you have the option of two methods of operation. The Johns-Manville is the only extinguisher you can discharge either by pumping or by compressed air previously pumped and temporarily stored. This latter method enables you to pump up the pressure as you run to the fire and then to shoot the stream without further pumping—a big advantage in close quarters.

The extinguishing liquid which immediately smothers any incipient blaze, including electric arcs and burning gasoline, is a chemical of a dielectric strength greater than transil oil. It is non-corrosive and harmless to skin or fabric.

Drains Your Steam Lines Back to Boiler Automatically Without Pumps

After steam's expansive energy is exhausted, there are heat units left. These the Morehead System returns to your boiler as pure HOT feed water. It lowers your fuel cost by 10 per cent.

It would pay you to talk with the owner of a plant in which the Morehead System is installed. **Write.**

MUELLER

E5010 For Water

Reducing and Regulating Valves

Before you install your valve, be absolutely sure on these three points.

1. **The right kind** of valve is the one that is adapted to your particular service. No one type will answer all purposes. Different service and at times different conditions in the same kind of service necessitates different types of valves.

2. **The right size** of valve is the size that will make the proper reduction and regulation and has a wide enough seat opening to prevent obstruction and cutting out of the seat. *A general fault is using a valve that is too large.* Ordinarily they should be smaller than the pipe to which they are attached.

3. **Proper assembling** means that valves should have working parts suitable to service, and diaphragms and springs suitable to pressure range.

Don't guess. Consult us. When valves are installed under MUELLER supervision, we fully warrant them to perform the service for which we recommend them.

We make valves for water, steam, gas, air, oil and ammonia. There is a stock valve in our catalog that will meet your needs. If you have a specially intricate problem to solve, our experts are at your command.

Established 1868

The Gripping Power of a Giant

is the gripping power of "Spiro" couplings; in fact, they have a 50% greater gripping force than any other compression coupling. The tigher the pull on the two halves of the coupling the tighter the grip on the entire length and circumference of the sleeve on the shaft.

A spiral slot in the sleeve is a patented Bond feature that allows a tremendous gripping force to be applied. There are no keys to break or work loose and cause time and labor to be wasted in fixing it.

"SPIRO" Couplings Cannot Slip

Write for our catalog on Power Transmission Machinery to-day.

Canadian Bond Hanger & Coupling Co., Ltd.
ALEXANDRIA, ONTARIO

WHEN a certain manufacturer bought his belts, the salesman told him to "run them at just the right tension."

So once a month every belt was tested, and if not tight enough it was taken up, this work being done on Sundays and holidays, at "time-and-a-half."

But this made his friction load high. Bearings required too much oil, and when his belts slipped, men and machines had to stand idle until they were taken up. So finally they used belt dressings, rosin, soap or "a little castor oil" to stop the slipping, and now his belts give him more constant trouble than anything else in the plant.

* * * * * * *

There is another man in his town whose belts are old. He hasn't tried the tension for many years, because there isn't any tension. They run easy or slack, and when called upon for extra duty they respond cheerfully.

For this man has long since learned the CLING-SURFACE way. His belts never slip, even when running heavy, and the friction load is very small. About once a month or oftener, depending upon how long the belt has been treated, one of his men takes a stick with a rag wrapped around one end, and dipping it in the CLING-SURFACE he places it against the face of a belt, passing it across until a very light stain appears on the pulley faces. Then he stops; that belt is trouble-proof.

Simple, isn't it? Yet the greenest workman can apply the new semi-liquid "easy-to-use" CLING-SURFACE safely, economically and correctly.

Instead of tying up the shop with "belt trouble," wearing out men and equipment, and having overtime charges to meet, ONE MAN, with a bucket of CLING-SURFACE, treats the belts. Oil, coal and time is saved, more power is delivered, and the drives become cheerful workers instead of disagreeable kickers in your factory.

Let us prescribe for YOUR drives; our service is free. CLING-SURFACE is guaranteed, and we have a plan 10,000 firms have found successful.

Remember, use CLING-SURFACE and you won't need belt dressings

POTATO SCALE POWDER

A Simple, Inexpensive Means of Saving Fuel

Canada will face a serious fuel shortage next winter. Every pound of coal should be conserved—right now. A little POTATO SCALE POWDER in the feed water of your boilers each day will save many tons of coal for Canada in the course of a few months. POTATO SCALE POWDER removes old scale from the boilers and prevents any new scale formations, thus your boilers are able to do maximum duty with a minimum amount of fuel. No pitting, foaming or other troubles, due to impurities in feed water, where POTATO SCALE POWDER is used.

Made to suit feed water conditions and contains nothing that will cause the slightest injury to boiler metal or fittings.

Large power plants in Canada and United States are constant users of POTATO SCALE POWDER. Positively guaranteed. Try a barrel and watch the result.

6 F Type Oil Filtering and Circulating System

Results that Count

Wherever it is installed there is more uniform lubrication of machines, without loss of oil; less depreciation of equipment; fewer repair bills; a better spirit among employees, and—increased profits, all of which are good, strong reasons why the Bowser should be in your plant.

The Bowser stores and supplies new oil—collects dirty oil—purifies it, makes it good as new—returns the proper supply to points of use wherever located. Its simplicity, durability, and ease of operation are reasons for its popularity in all well regulated plants.

"Results that Count" always follow its use—we'll be glad to tell you more about it if you drop us a line.

BOWSER ESTABLISHED 1885

BOWSER SERVICE

"We have been using this belting on practically every kind of drive throughout our shop and have no hesitation in saying that same has given us entire satisfaction."—A Pembroke Superintendent.

Plays a Big Part in Shell Production

Three years ago it was unusual to find any belting except leather in machine shops.

To-day hundreds of Canadian shops are using Extra Power Belting. Some are belted entirely with Extra Power. One of the largest shell shops in the Dominion has used over 20,000 feet—practically every drive belt is Extra Power.

In fact, Extra Power Belting is playing an increasingly big part in Canada's shell production.

It is true that engineers and factory superintendents first discovered the merits of Extra Power Belting on hard, unusual drives.

But experience in shell shops has shown that Extra Power Belting is not a bit too good for ordinary drives.

The proven qualities of Extra Power Belting—long life, pulley-gripping flexibility, freedom from stretch—make it the best and most economical belt for high-speed lathes and every other type of machine.

Don't think you have paid for a belt when you have bought it. That's only the beginning of the belt cost.

To that first cost must be added the cost of every repair or adjustment on the belt—every hour machinery and men are idle—every dollar of the product's value lost by that idleness—every pound of coal wasted in inefficient transmission.

The Goodyear Belting man has a real story to tell you. He is a trained expert on belting problems. To use his service involves no obligation, adds nothing to the cost of your belting. But we *may* be able to show you a new road to increased production and lower belting costs.

Write or phone the nearest Goodyear branch—to-day.

CONDUIT PIPE FITTINGS

Made in Canada

TYPE A

TYPE B

TYPE F

TYPE V
Vapour, Gas and Dust Proof

In introducing to the trade C.G.E. Conduit Pipe Fittings, we desire to call particular attention to the following points, in connection with their manufacture:

All C.G.E. Pipe Fittings are made of pure metal, carefully selected to ensure proper tapping and threading, well-japanned on the inside and electro-galvanized on the outside.

The cover openings are ground thoroughly flat and screw holes well centred.

All covers are fitted to castings before shipment, to avoid possible drilling error or extreme shrinkage of porcelain.

In general quality, high finish and uniformity of product, C.G.E. Fittings compare most favorably with any other make on the market.

Every shipment is warranted to maintain this high standard—samples will gladly be forwarded free of charge, on request.

C.G.E. Fittings comprise all standard types.

C.G.E. Fittings are approved by the National Board of Fire Underwriters and by the Hydro Electric Power Commission of Ontario.

——AND THEY COST LESS MONEY.

Bulletin No. 618, describing these fittings, will be mailed on request to our nearest office.

GROWTH—

Day after day, week after month, for the five years that Economy Fuses have been on the market, the sales have maintained a constant gain—not alone in volume but also in percentage of increase. This is because

ECONOMY renewable FUSES

are absolutely accurate in operation and cut annual fuse maintenance costs 80%. An inexpensive Time Delay Renewal Link restores a blown Economy Fuse to its original efficiency.

Order to-day from your electrical jobber or dealer. Write for Catalog 24.

ECONOMY FUSE & MFG. CO.
Kinzie & Orleans Sts. Chicago, U.S.A.

Sole manufacturers of "ARKLESS"—the Non-Refillable Fuse with the 100% Guaranteed Interrupting. Economy Fuses are also made in Canada at Montreal.

Scandinavia Belting

Works Well In Hot Places

A NUMBER of instances have been brought to our attention where for transmission work in hot places Scandinavia was the only belt that would stand up. Even our competitors frequently recommend their customers to come to us when other kinds of belting have failed.

The dressing with which the belt is impregnated in the process of manufacture resists the action of heat and keeps the belt soft; this dressing, if the air is hot, will eventually dry out, and in cases of this kind the belt should be treated with a proper dressing occasionally to keep the belt soft and pliable.

We are often asked about the stretch in this belt. Yes, it does stretch and when hot there is quite a little stretch. If the belt is to be run where hot, leave the belt for some time where it can become well heated, then put on with a belt stretcher. Most of the stretch can be taken out in this way. Lots of Scandinavia belts are running fans in drying kilns, and are doing the work more satisfactorily than any belt previously used.

If you are in doubt about the purchase of a belt, write us.

NOTE.—Do **not** use "bar" or "stick" belt dressing on textile belts.

FEDERAL ENGINEERING CO. Ltd.,
172 JOHN STREET, TORONTO

More than Half the Oil You Buy is Wasted.

Anderson Pressure Oil Filters

Subject drip-pan-collected oil to the same cleansing and purifying treatment as that of oil refiners. By no other method can used oil be rendered absolutely clean and pure.

Anderson Pressure Filters of the type illustrated have dropped to one-half and less the oil bills of hundred of firms in the United States and Canada. Consider that more than half the oil you buy is wasted, unless you have an Anderson Filter to prevent waste, and at once it is apparent you should

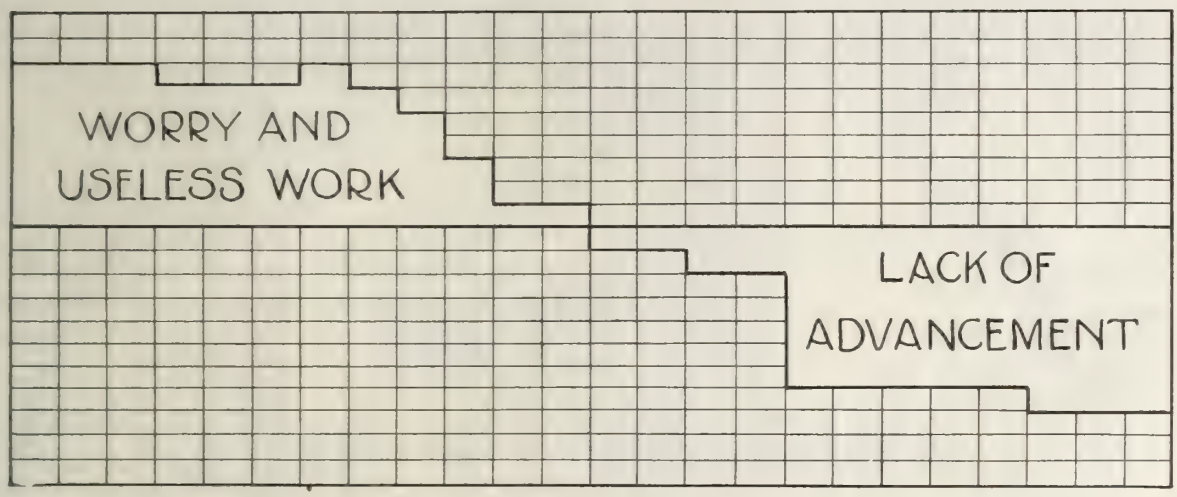
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary,

Canadian Association of Stationary Engineers

230 Caroline Street Hamilton, Ont.

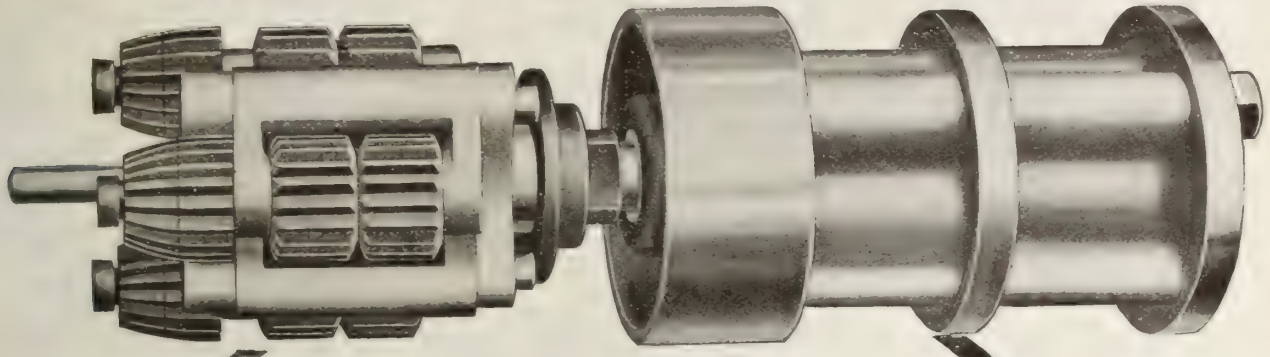
CLEAN YOUR BOILER TUBES

IN LESS TIME, WITH LESS POWER



You can remove all of the scale and keep the tube surfaces clean and polished by frequent use of

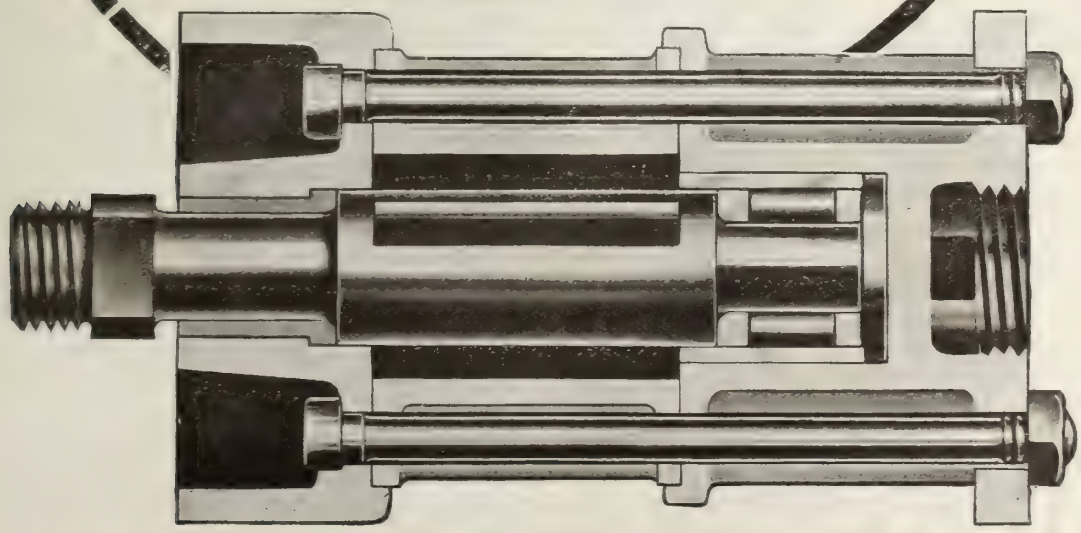
ROTO TUBE CLEANERS

Unrivaled in speed and durability. By far the cheapest cleaners because of their high efficiency. They combine the most powerful, reliable and durable motors with the most effective scale-removing tools.

Hardened Steel Armor Rings thoroughly protect the motor. The hard steel rings keep it straight, round, up to size and a correct fit for the boiler tube, even after long use. Roto motors cannot pass over scale or get wedged and stuck in the boiler tube. They positively eliminate the usual trouble of wearing oval, taper or undersize.

Roto Tube Cleaners include air, steam and water driven, cleaners for all kinds of straight and curved tubes of iron, steel, cast iron, copper, brass, etc., in boilers, fuel economizers, heaters, condensers, evaporators, etc.

Write for Catalogues now.



THE ROTO COMPANY, HARTFORD, CONN.

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CATALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.**

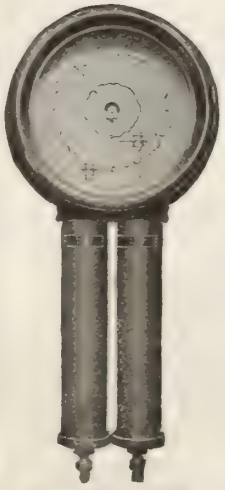
UEHLING WASTE METER

COMBINED

CO_2 AND TEMPERATURE RECORDER



Record of CO_2 and stack temperature on one chart.

Does your fireman know how much fuel he is wasting? Do you know?

The **Uehling CO_2 Recorder** makes a complete 24 hr. record of your combustion efficiency and the **CO_2 indicator at the Boiler Front** holds the fireman responsible.

Get more **Steam** per pound of **Coal** and reduce your annual fuel consumption.

Let us know the number and size of your boilers and coal consumed per year, upon receipt of which information we will be glad to send you full particulars.

CO_2 Indicator for Boiler Front

Let us hear from you. We are pioneers in the manufacture of Indicators and Recorders for Power Plant purposes.

Send for our Bulletin No. 110.

Boilers for all Services

INGLIS quality has not been attained in a day or a month or a year or two. It represents the fruit of over half a century in meeting the requirements of boiler users.

Inglis boilers are Canadian standard in materials, workmanship and efficiency. They ensure a lifetime service with a minimum of repairs.

We are also sole Canadian makers of Erie City Water Tube Boilers, Vertical and Horizontal.

Our representatives will be pleased to show installations of our different types of boilers to prospective customers.

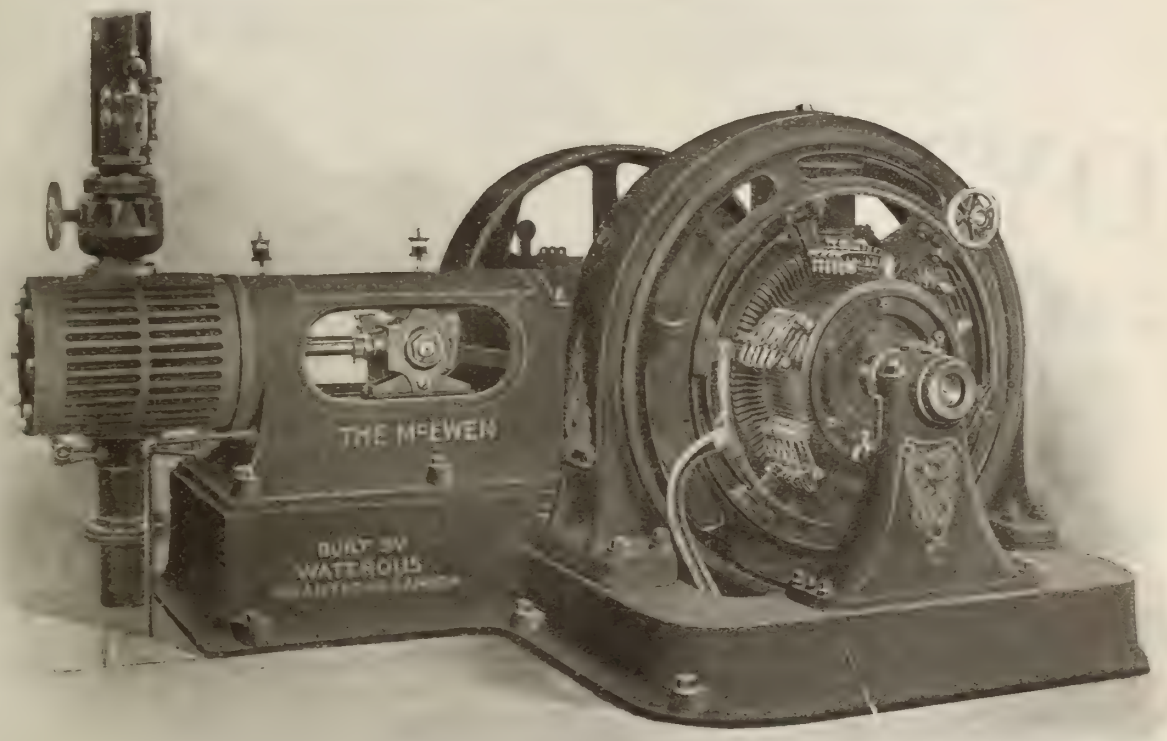
"The McEWEN"



THIS illustration represents our Horizontal Automatic High-Speed Engine, which we build in simple and compound units from 10 to 700 horse-power. Heavy, rigid bed designed for accessibility and for endurance. Cross-head guides, main bearings, and face for cylinder attachment, are machined in one operation to ensure perfect alignment. Cross-head guides are cast as part of the frame. They cannot be misadjusted. Valve of the piston type, perfectly balanced in every position, and is practically frictionless. Valve is double-ported. Balancing pressure plate is slotted to correspond with valve seat. Produces additional passage to cylinder by providing double admission and exhaust edges. Relief valves are made absolutely unnecessary. Guaranteed control by our famous Begthrup Inertia Governor. The McEwen Engine is adapted to all kinds of work. Its particular field is driving electric generators, for lighting, power, street railway and mine haulage. Every engine built on the duplicate part system, and thoroughly tested before leaving our works.

Every Barrel of **BOICO** The Quick Remover and Positive Preventive of Boiler Scale

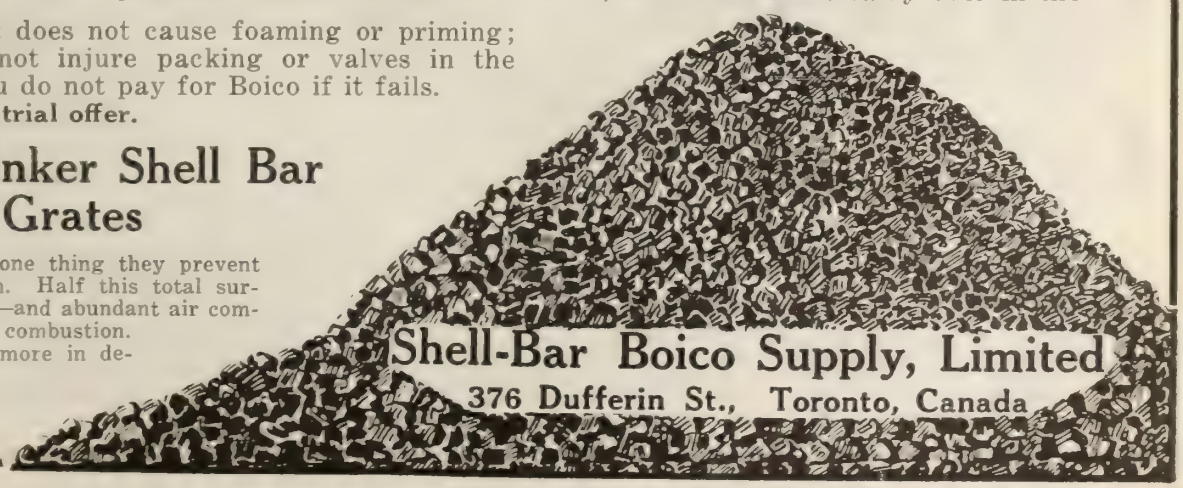
SAVES A PILE OF COAL

It's such a heartless job trying to keep a boiler clean with ordinary compounds that comparatively few are always wholly clean. Consequently a good deal more fuel than need be is burned up on the grates. We claim for Boico that it removes absolutely all scale; that it positively prevents further formation of scale; that it does not carry over in the steam; that it does not cause foaming or priming; that it does not injure packing or valves in the slightest. You do not pay for Boico if it fails.

Write for our trial offer.

Anti-Clinker Shell Bar Grates

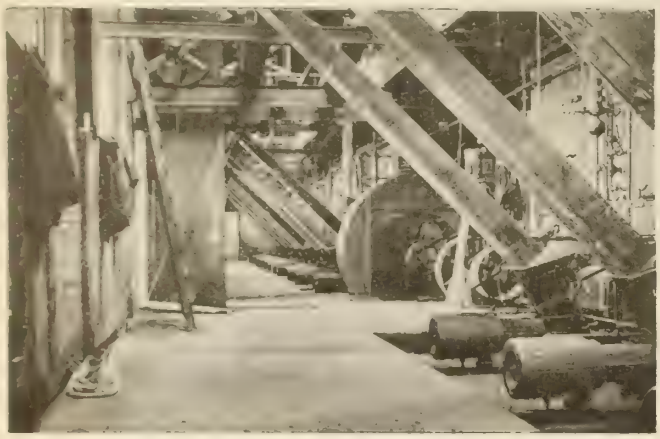
save coal. For one thing they prevent clinker formation. Half this total surface is air space—and abundant air commands perfect combustion.
Let us tell you more in detail.



Shell-Bar Boico Supply, Limited
376 Dufferin St., Toronto, Canada

Steady Steam Pressure Always With 15 to 25% Less Coal

Yes—15 to 25% of your present fuel bill saved! Surely that alone is reason enough for you to discontinue the old, uncertain and ever costly method of stoking. How much better it would be to have a smokeless stack—the fuel gases that go into smoke used to make steam; or, instead of the good intentions of a fireman, to have the scientific exactness of the



JONES UNDERFEED STOKER

It is perfectly automatic—the simplest stoker built. It maintains the steam pressure, **"saves and serves."**

Write us for Catalog.

Jones Underfeed Stoker Company, Limited

37-41 Britain Street - - TORONTO

Cyclone Grates

To Get All the Energy Out of Low-Grade Coal

To get all the energy out of screenings or the best hard coal you can buy, use Cyclone Shaking and Dumping Grates, because their 60% air space and 90% underdraught insure perfect combustion. No atom of heat energy can escape. No clinker can form. And no good fuel can get into the ash pit. Their new jarring, shaking movement lets the worthless ashes through—but nothing else.

Engineers in the city for Exhibition will be most cordially welcomed at our plant at 20 McGee street, where we would be glad to demonstrate the Improvements in the Cyclone Shaking and Dumping Grate Bar.

PRODUCT

THE GALT SPRINKLER STOKER

For smokeless and economical combustion and utilizing low-grade fuels.

The Galt Sprinkler Stoker is a real Coal saver, and can be installed on Power and Heating Boilers, Annealing Furnaces, and in all classes of Installations.

Will burn any kind of fuel from anthracite dust up to 3" lump.

ADVANTAGES

They give complete and smokeless combustion.

They feed the fuel to the furnace with the doors shut.

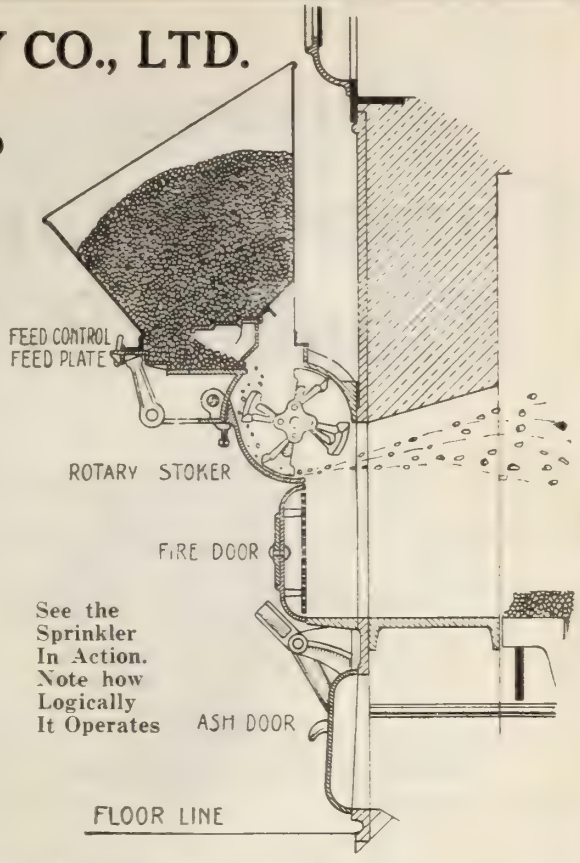
They do not require skilled firemen.

They maitain a brilliantly hot fire.

They are simple, strong, and beautifully made.

The Galt Sprinkler Stoker automatically feeds and uniformly spreads the fuel to the furnace in a light, continuous stream, and gives a perfectly level fire 3 to 4 inches thick.

Send for one of our Combustion Engineers to look over your plant—no obligation.



See the Sprinkler In Action. Note how Logically It Operates

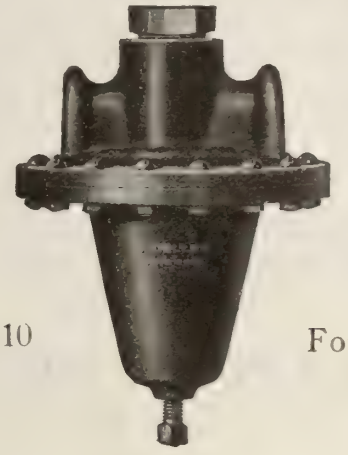
MUELLER



E5010 For Water

Reducing and Regulating Valves

Before you install your valve, be absolutely sure on these three points.

1. **The right kind** of valve is the one that is adapted to your particular service. No one type will answer all purposes. Different service and at times different conditions in the same kind of service necessitates different types of valves.

2. **The right size** of valve is the size that will make the proper reduction and regulation and has a wide enough seat opening to prevent obstruction and cutting out of the seat. *A general fault is using a valve that is too large.* Ordinarily they should be smaller than the pipe to which they are attached.

3. **Proper assembling** means that valves should have working parts suitable to service, and diaphragms and springs suitable to pressure range.

Don't guess. Consult us. When valves are installed under MUELLER supervision, we fully warrant them to perform the service for which we recommend them.

We make valves for water, steam, gas, air, oil and ammonia. There is a stock valve in our catalog that will meet your needs. If you have a specially intricate problem to solve, our experts are at your command.

Conserve Canada's Coal Supply

There is an urgent need of Coal Conservation in Canada. The war has created a demand far in excess of the sources of supply, and next winter may see Canada facing a critical fuel situation. Under these circumstances it becomes the patriotic duty of all users of fuel to conserve Canada's coal piles to the fullest extent of their ability.
There is no surer and more practical method of conserving coal in the power houses of Canada than through the use of—

COPPUS TURBO BLOWERS

They will add from 25 to 100% to the rated capacity of your boilers—and as much as 200% if operated in connection with mechanical stokers. Then, too, you can burn the cheapest fuel you can buy and get maximum results.

If you are not getting an evaporation of from 4 to 6 pounds of water per hour, per square foot of heating surface of your boilers, it means that you are not operating at maximum efficiency and it is both good business and patriotic, under the present demand for coal conservation to remedy the matter at once. And all you need is sufficient draft and a means to control it according to requirements. Right here is where COPPUS TURBO BLOWERS solve the problem. The draft is absolutely under control at all times and in any amount that you may need. Boilers can easily be forced up to 200 per cent. of normal rating. Their steam consumption is very small, only half as much as a number of other makes—and the boiler efficiency is greatly increased. This means fuel conservation and less trouble all round.

There never was a time to practice fuel economy in the power house like the present, and there's no surer and more practical method to this end than through the adoption of Coppus Turbo Blowers.

Write for full details.

There is a FRICK Machine for every refrigerating purpose—all types—Vertical — Horizontal — Absorption.

Conserve Meat—Eat More Fish

And now the fish industry has come into its own. But without artificial refrigeration, only a few persons could comply with this request.

The proper preservation of fish requires constant low temperatures, but to maintain them economically, heat leakage through the walls, floors and ceilings must be reduced to a minimum. Here, therefore, as in all other cold storage rooms, proper insulation is of vital importance. Hence the most up-to-date fish freezing and storage plants, as well as a score of other industries, are using

DAVIS

PRESSURE REGULATORS

CAN SAVE STEAM IN EVERY PLANT—IN YOUR PLANT

In big power plants and in little plants, correct steam pressure for the various uses is essential to economical operation. The Davis Pressure Regulator saves steam by reducing the generated high pressure to the lower pressures as needed.

The desired pressure is obtained by adjusting the number of weights on the lever arm. The pressure is *weighed*, because the Davis Pressure Regulator is built like a pair of balance scales—just as simple and just as accurate. As simple and unfailing as the law of gravity, because it is controlled by gravity. There are no springs; no diaphgram to give trouble.

The new valve booklet contains some mighty useful information about valves and piping and will be sent free on request to the G. M. Davis Regulator Co., 144 Milwaukee Avenue, Chicago

Selling the Buyer

BEFORE you make a sale it is only reasonable to assume that the buyer must be made familiar with the article or appliance you wish to sell. More than that, he will likely demand to know who you are, where you are, and all about you, or sufficient about you to enable him to determine what you have in the way of reputation to back the goods you have for sale.

THE process of making an actual buyer out of a prospect consists primarily in educating him. Education in all branches of endeavor is best accomplished by means of the *printed word*. It is not only the most effective medium, but it is the most *economic*. It not only accomplishes what it is intended to do, but it does it with the least possible expense.

IN every branch of commercial and industrial life we have to-day the *technical* or trade journals. Only the unthinking underestimate the power of those educative mediums. Their rapid growth and increasing circulation alone are convincing evidence of their usefulness. They are specialists in their respective fields of endeavor.

They are the great disseminators of practical information and trade news. Their clientele is made up of sober, thinking, ambitious, responsible mechanics and business men. The idly curious and irresponsible do not read them.

IT is because the technical journal is educational in character that so many manufacturers recognize in it the ideal medium for *educating* their army of probable buyers and customers to understand and appreciate the merits of their respective lines. It is because of this recognition and as a result of it that the advertisements of to-day are so vastly superior to the advertising of a few years ago, when, perhaps, the pulling power and value of the printed word was not so generally appreciated.

POWER HOUSE

European Practice in the Design of Induced Draft Plants

Mechanical Draft Has Several Advantages Over Natural Draft —Induction Method Gives Excellent Results in Practice and Has Been Found to Give Considerable Saving in First Cost and Maintenance Expense

By FRANK C. PERKINS

THE general construction and details of mechanical draft for furnaces may be noted in the accompanying illustrations and drawings as designed by Engineer Louis Prat, of Paris, who points out that the problem is to put in contact with a given weight of fuel a definite quantity of air, so that combustion will be as perfect as possible.

The ideal draft is that which permits of a constant relation between the weight of fuel and air at all rates of combustion. The brick chimney fails completely in this duty and in addition presents the serious inconveniences of great irregularity of the draft, which varies with the temperature of the gases, condition of the atmosphere and extremely low efficiency. Calculations show that this does not reach one per cent even when compared with an average power plant and allowing for the loss of heat inevitable in a boiler plant.

It is maintained that the useful power is very low with brick chimneys in consequence of the shape of the draft necessary for the requirements of stability, instead of the conical bell-mouth shape evase chimney, called for by the laws governing the escape of gases.

There is also an enormous bulk and weight for the small draft created. This means high price for the chimney alone, and it is frequently doubled when the cost of foundations are included. It is held that the capital cost in works operating on chimney draft is always much greater than in the case of mechanical draft and it must not be overlooked that the more economically a boiler plant works the more pronounced are the inconveniences of the chimney, since the better the utilization of the heat the lower the chimney temperature and consequently the draft.

In a well managed boiler house it is possible to have an economiser outlet temperature of about 300 degrees Fah., say an average chimney temperature of 260 degrees Fah. To produce a draft of 1.2 in water gauge under these conditions would call for a chimney 300 feet high, assuming the air temperature at 60 degrees Fah. But as a well designed plant should work equally well in summer and winter, if the low temperature is assumed, it would be necessary to have a chimney over 400 feet high. These heights are for the theoretical or calculated draft, the actual draft might be reduced by anything up to 20 per cent. In a word, the chimney is the result of custom, force of habit, and is primitive.

Natural draft by fires has been long abandoned in many mines, although in their case the pit shafts form suitable chimneys, because it has been shown that the chimney method takes from 50 to 60 times more power than a properly designed fan installation.

The fallacy of steam jets is pointed out as the efficiency of steam jets is, like the chimney, also low. Without going into the complex theory of injectors it is an easy matter to verify their high steam consumption. It is proved by tests that an excellent steam jet installation never takes less than 4 per cent of the total steam evaporated by the boiler, but in actual practice that figure is generally at least doubled, and examples up to 15 per cent. are not unknown.

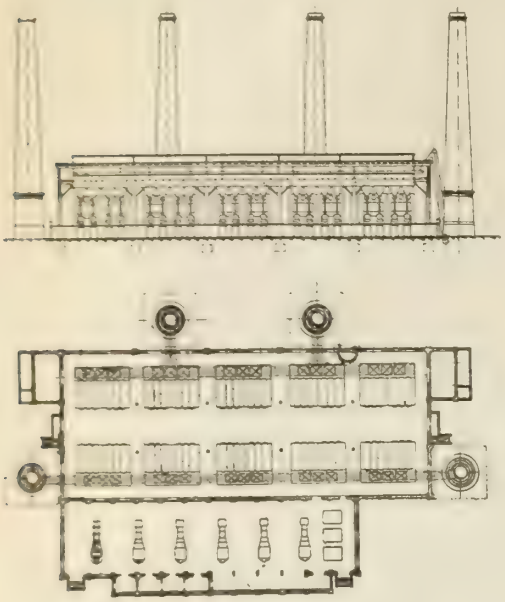
In comparing the energy in the steam used, to the useful work of supplying air, represented by the product of the pressure at the ash-pit and the volume of air supplied, the efficiency is found to be always less than 1 per cent. This low efficiency, due to the incorrect use of the expansion of the steam is aggravated by general misuse in practice. One can easily see that it is uneconomical to pass the large amount of air necessary for combustion through a bottle necked restriction where it attains enormous speeds and an instant afterwards, allow it to expand in an ashpit of large cross section. The best illustration of this is the necessity for open ashpits when the jets are stopped, i.e. when an attempt is made to work on chimney draft. The thin or blow pipe flames, the fire burning in holes, the depositing of coal dust on the boiler tubes and the increasing the difficulties of cleaning are all practical inconveniences well known to users of steam jets for draft productions.

A comparison of various systems of mechanical draft will be of interest, sho...

4,000 H.P. INDUCED DRAFT PLANT OF THE SECTEUR ELECTRIQUE DE CHAMPS ELYSEES A PARIS.

ing the only logical solution of the draft problem is the fan. A fan can be used in several different ways. Forced draft and suction draft or by aspiration and also mixed draft or by variable blowing as well as the system of induction are all used.

It is a mistake to confuse suction draft with induced draft. This system works by induction and the fan plays only a minor part in the aspiration of the flue gases. To compare clearly the respective qualities and limitations of various draft systems take a boiler with one air passage. The pressure in this passage varies at different points. At the point where it is equal to the pressure of the atmosphere it is the custom to call it [illegible].



TRIESTE MUNICIPAL POWER STATION IN AUSTRIA, DESIGNED FOR NATURAL DRAFT.

Mechanical draft, giving practically unlimited suction at the chimney, is alone able to satisfy, without limitation, any rate of combustion and evaporation, the demand whatever it might be. But here a practical and fundamental distinction must be made between the ordinary mechanical suction draft and induced draft. It is that of the motive power absorbed and the size of the apparatus. In the direct suction draft the damper must always be closed, if not the fan works in short circuit, without useful effect. It is necessary then to pass the whole volume of flue gas through the fan, resulting in a fan of enormous size. If, in order to reduce the capital cost, a smaller fan is installed, as is sometimes done in practice, the resistance to the flow of gas is increased considerably. Not only is the benefit of the natural draft lost, but the total resistance of the circuit is increased in such a way that finally the work on the fan is augmented considerably, both on account of the supplementary resistance due to its presence and to the fact that it works on too large an orifice.

In the induced draft system the difference is fundamental. The damper, which might well be omitted, is always open, the chimney is freely divergent, and the resistance of the circuit having been practically unchanged, the benefit of the natural draft is retained. In addition a very small fraction only of the total gas passes through the fan, which transfers to it a pressure sufficient for the draft requirements, a double reason for not using cumbersome fans. The pressure generated is utilised after the manner of a propelling jet in an injector, to create the complement of draft necessary for the flow of gas, hence the name pressure transformer given to this type of chimney.

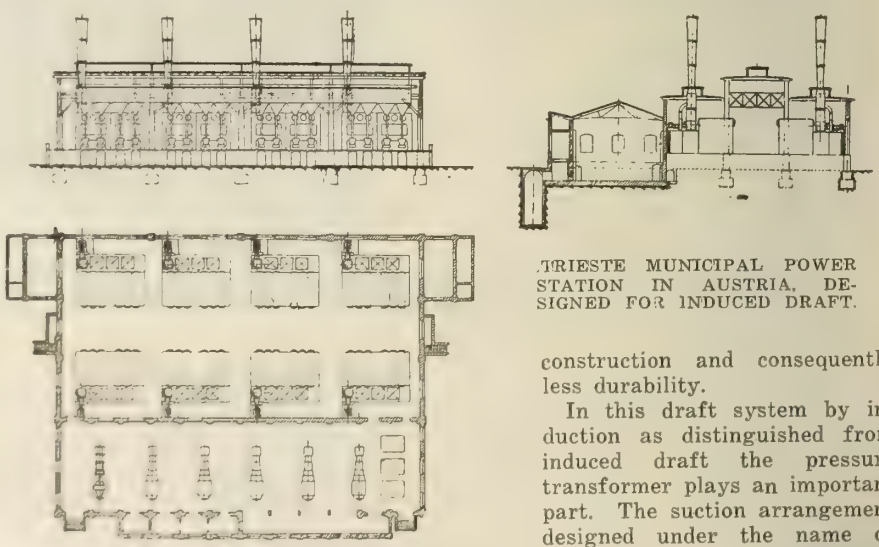
The power necessary consists of nothing more than that necessary to accelerate the natural draft, autovariable between certain limits and the fan, working on a reduced orifice, can be designed to give the maximum efficiency. Then, extremely small power, small size and simplicity of installation, these are the practical characteristics of this system of draft by induction.

It may be of interest to consider the limitations of forced draft systems. The systems called compensated, balanced and proportional are in fact, forced draft systems offering in consequence the criticisms well known to which must be added the necessity of an automatic regulator controlling the damper. These systems all aim at the same object, i.e., to maintain automatically in the furnace a pressure equal to that of the atmosphere.

It is said that in this way air infiltration is reduced but only within small limits, because from the furnace, which is usually slightly below zero pressure, the suction or draft increases up to the damper. The more volatile the coal, the less is it possible to obtain zero pressure in the furnace owing to the back-draft and the liability of explosions. This simple and doubtful advantage of reducing infiltration of which one should not overestimate the importance, with boiler settings and flues as normally maintained, is sometimes obtained at the price of complications to be avoided in practice, on one side an automatic regulator controlling the speed of the fan, on the other an automatic damper regulator, parts undesirable for ordinary boiler-house use.

Induced draft avoids the very serious inconveniences inherent in the forced or balanced systems where air is supplied under pressure, below the grates. The installation is simple, the excavation and flues are avoided, the loss of pressure due to bends is less, the burning of fire-bars and the blow-pipe flames are suppressed, but as pointed out, the method is conducive to abnormally large fans. For example in order to burn 3,500 lbs of coal per hour, it is calculated that a fan having an impeller over 6 ft. diameter would be required; large enough to ventilate an important mine.

In order to overcome this difficulty one is tempted to use a fan too small for the orifice on which it has to work. In order to reduce the dimensions and consequently the selling price, it is not unusual to install fans running at excessive speeds and low manometric efficiency. These are points to be considered seriously and further economy on weight means lighter construction and consequently less durability.



TRIESTE MUNICIPAL POWER STATION IN AUSTRIA, DESIGNED FOR INDUCED DRAFT.

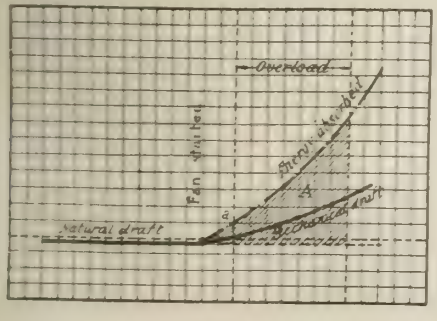
In this draft system by induction as distinguished from induced draft the pressure transformer plays an important part. The suction arrangement designed under the name of pressure transformer comprises essentially a steel chimney comparable to an injector. The suction inducing the flow of gas is created by leading into the contraction chamber the propelling jet of gas discharged from the fan through the nozzle. In the event of stoppage of the fan, the effect is produced by a

3,000 K.W. INDUCED DRAFT INSTALLATION OF THE CENTRALE DE ROME, ITALY.

steam ejector which acts as a standby. The whole forms a substantial apparatus wholly constructed of heavy boiler work, without a moving part. The propelling jet can be either atmospheric air or hot gases from the flue.

In the one arrangement, called out of circuit, the fan is completely out of contact with the gas, and consequently is in the best position for preservation. However, the addition of cold air lowers the temperature of the gas and the useful effect of the natural draft is reduced in the proportion of cooling. Another arrangement called in circuit: the fan deals with hot gas as in the case of ordinary suction draft, but the injection of cold air is obviated, and consequently the power necessary becomes extremely small.

It is pointed out that there is sometimes found a general prejudice against the steel chimney, which is said to have a very limited life. It is well to remember that this criticism is only correct in



CHARACTERISTICS OF MECHAICAL DRAFT SYSTEMS.

cases where thin steel plates are used. It is necessary before everything to ensure constant operation and plates of ample thickness should always be employed.

There are many installations which have been at work for fifteen years without stoppage or repairs and when properly constructed there is no reason why steel chimneys should not have very long lives. There are cases in England and America where such have been in constant use for forty years or more.

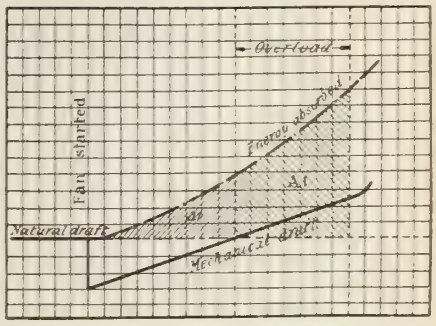
The construction of the fan with one opening is largely used and it is said the mechanical efficiency never falls below 60 per cent and the manometric efficiency is almost always equal to unity. This explains their ability to run at much lower speeds than usually met with in current practice. In the fans dealing with the flue gases directly the external blades produce scouring air currents which thoroughly cool the pedestal and bearing. This is a distinct advantage over the usual method of water cooled bearings, as it is simple, absolutely automatic, and requires neither attention nor upkeep. The bearings, which are easily dismantled, are of the flexible type fitted with oil ring lubrication and have a length equal to four times the diameter of the shaft.

In the past, mechanical draft has been frequently criticised on the ground of less security from stoppage than that given by a chimney. It has been the experience of some users that for one reason or another, probably carelessness or accident, the fan had stopped, causing great inconvenience owing to the fall in draft. With the ordinary suction draft arrangement the only remedy is a second fan as a reserve. This means considerable increase in first cost and additional space. In this system the reserve fan is superseded by a steam jet. Unlike the injectors used for forcing air under the grate bars, it is possible to so design the diffusers that the steam is properly utilized and the reserve draft is thus obtained without excessive steam consumption. Moreover this steam injector might in case of necessity, work simultaneously with the fan. In this way it would be possible to double the draft, which might prove a great convenience, say at a time when there was an abnormal demand for steam, or in the case of a temporary shut-down of one boiler in a battery.

The characteristic features of this draft plan are of interest. A most important feature of this induced system of Louis Prat is its ability to use the greatest possible part of the natural draft due to the hot gases in the chimney. This is owing to the fact that the pressure transformer adds little or nothing to the resistance of the circuit, whilst a fan, dealing with all the flue gas, causes extra resistance almost always greater in amount than the natural draft previously available.

In the induced draft the damper is kept fully open and the only resistence, infinitesimal, is that represented by the reduced section of the aspiring chamber. The result is that the natural draft is utilized almost entirely and the energy wasted, is considerably less than with ordinary suction draft.

The advantages of mechanical draft are less disputed as the number of installations increase. Years ago, one



CHARACTERISTICS OF INDUCED DRAFT SYSTEMS.

found only systematic opposition and skepticism, whereas to-day one looks for mechanical draft in most new installations and applies it more and more to existing plants. The graphic representation of the growth of these installations is particularly suggestive and it has been brilliantly crowned by the most important mechanical draft installation in the world, that of the C.P.D.E. (the Paris Electricity Distribution Co.) which has installed the induced draft for boilers equal to 180,000 h.p. capacity.

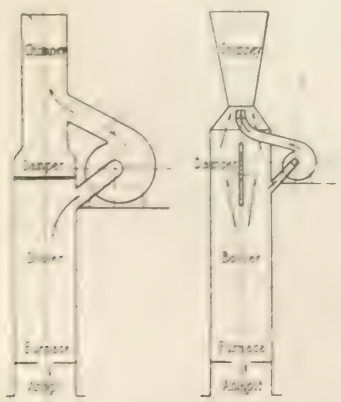
It is urged that the principal advantages include flexibility, thus making it easy to keep up with the demand for steam. Economy is made easy by the great facility with which the air supply is controlled to suit the rate of combustion and nature of fuel, steady draft independent of atmospheric and other changes usually met with in boiler house practice, thus making for efficient operation.

Regarding the steam raising units and the great reduction of capital costs, either when applied to a new installation or to the extension of an existing plant, it is held that this point is of more than passing interest. In consequence of the great elasticity, the ease with which it can be

15,000 H.P. INDUCED DRAFT SYSTEM WITH 5 TUBES AT PLANT OF THE SOCIETE ELECTRIQUE "LE TRIPHASE" AT ASNIERS, FRANCE, ON THE SEINE RIVER.

started up and the ability to force the fires to the utmost limit, it becomes easy to satisfy the variable demands for steam with the minimum number of boilers in operation. This is a matter of great importance, seeing that it reduces the standby plant and the number of banked fires, the effect of the latter, from the point of view of fuel consumption alone, is well known to those familiar with central station practice.

An advantage which must appeal to those responsible for public service supply lighting, traction, or motive power is the increased security in the employment of separate chimneys instead of a single large chimney. In case of accident to a chimney the whole of the boiler plant may have to be shut down and in increasing the number of units this possibility is so much diminished. This idea was first developed in large electric power stations. It is adopted for example at the large three phase power station at Asnieres, near Paris, at the Grand Quevilly Power Station, supplying Rouen, and at those of Trieste, Victoria Falls Power Co., Sampierdarwna, all of which are equipped on the induced steam here considered.



MECHANICAL DRAFT SYSTEMS.

The reduced capital costs are important. This point is clearly explained by the suppression of flues and chimneys, costly in themselves and by the foundations and earthwork which they require. The saving on land and buildings, the space required being less, and the reduction in standby boilers are of equal importance. These different factors play a most important part in new schemes, inasmuch as they make for a great reduction in capital expenditure.

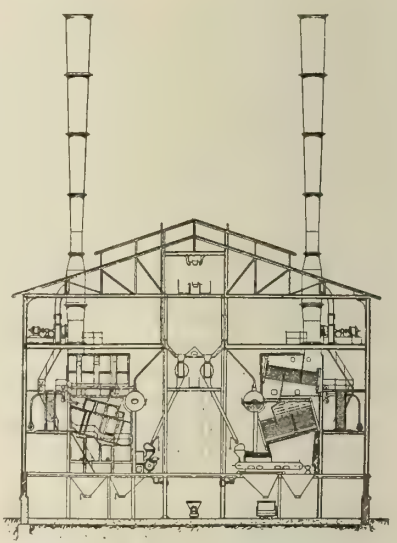
Two schemes were proposed for the Municipal Electricity Station at Trieste, Austria. The first with natural draft, was abandoned in favour of the induced system, which permitted a great reduction in land and buildings as well as in boiler plant and figures were given in support of the above statement. They were prepared for another large station and show a saving of $65,000 on the initial cost and $6,000 on the annual operating expenses. On the strength of this the administration of the Centrale du Grand Quevilly, near Rouen, decided in favour of the induced system.

Regarding the induced system applied to brick chimneys it is pointed out that in many cases when considered for existing installations, it is simply desired to accelerate the natural draft and the pressure transformer is specially suited for such application, as its small size enables it to be placed inside an existing brick chimney. In this arrangement the benefit of the natural draft, due to the height of the chimney, is retained.

The insertion of the turere and blower increases but very slightly the resistance of the circuit, so that the power necessary to produce the acceleration is extremely small. There has been an application of this kind made on a plant of 55,000 h.p. at the Central Power Station at St. Denis, near Paris. Each chimney is 182 feet high, enclosing a presure transformer dealing with the flue gases from six boilers, each having 4,550 sq. ft. heating surface. Before mechanical draft was adopted, the natural draft varied from .6 in. to .88 in. w. g., varying with the seasons, the hourly evaporation of each boiler varied between 16,500 and 17,600 lbs. After the installation of mechanical draft the evaporation could be increased to 31,000 lbs. per hour with a draft of 1.42 in. w. g. at the chimney base. The results obtained at the tests with six boilers at work are of interest.

Rate of combustion per sq. ft. of grate per hour	H.P. absorbed	Power absorbed in per cent. of steam produced
16.1	Natural draft	Nil
20.6	22.2	0.25
22.1	47.9	0.42
24.0	85.5	0.76

It is unnecessary to dwell upon the low motor power required. As to fuel economy it is claimed that the possibility of economic steam raising is another advantage of the induced system. This economy is due not only to the facility with which the draft may be controlled,



INDUCED DRAFT INSTALLATION AT GRAND-QUEVILLY POWER STATION NEAR ROUEN.

thus permitting a proper relation between the weight of fuel and air in order to maintain high CO_2 values in the flue gas at all loads, but to the fact that it makes possible the use of extremely low grade fuel. It is common knowledge that the poorer classes of fuel, slack, dross, screenings, coke waste, etc., have a market value much below that commonly used for steam raising purposes although their actual caloric value may be at least equal to the latter.

It is possible to buy more B. T. U. for a given sum, but this could not be taken advantage of unless the necessary draft could be guaranteed at all times. Small coal, which always calls for strong draft, is dealt with very satisfactorily on this system. Not being limited by insufficient draft, it is possible to reduce the air spaces between the firebars and thus reduce the loss due to unconsumed fuel falling into the ashpit, an important

point when dealing with small fuel.

Again the great increases in furnace temperature, owing to the higher rate of combustion, is in itself favourable to improved combustion and ensures more efficient smoke consumption. The induced system has low power consumption and with the ordinary suction draft arrangement where the fan deals with the whole of the flue gases, the power required is at least 2 per cent of the total steam generated by the boilers and frequently this figure is increased to 3 per cent. With the induced draft and the fan out of circuit, the figure is 0.5 per cent. to 1 per cent and with the fan in circuit 0.3 per cent.

On account of the low power consumption a large electric power station near Paris adapted this induced draft system. The problem to be solved was the following: Given a battery of 10 boilers each of 22,000 lbs. normal evaporation per hr. and working on the same chimney, how to increase the evaporation 50 per cent i. e. to a total 330,000 lbs. per hour.

The simplicity of installation is important as well as the reduced size. Besides the technical and economic qualities, draft by pressure transformation possesses practical advantages which are important in themselves. The great simplicity of fixing, owing to the small size, permits of a solution to the most difficult case where space is valuable or limited.

With forced draft, automatic or not the costs and difficulties of installing are greatest on account of the necessity for flues or ducts from the fan to the ashpit. With the ordinary suction draft these ducts are unnecessary, but the fans, always large for reasons explained, are often difficult to instal and it is necessary to have cumbersome connections from the fan to the flue and chimney.

The great facility with which the induced system lends itself to a good layout is clear apart from the fan, which is certain in action and calls for no attention other than lubrication. the installations have no moving parts, there is no weak link or part likely to get out of order through dirt and dust or inattention of the staff. To those familiar with the rough handling to which boiler-house plant is frequently subjected, the qualities of strength and reliability in operation without undue attention or maintenance are, without doubt amongst the most prized of all the advantages of this system.

The consideration of mechanical draft for kilns is important and there has only been considered the combustion in boiler furnaces but it goes without saying, it applies equally well to furnaces in general. By the employment of a rational method of draft it is possible in most cases to improve considerably the output or useful effect of the plant.

For cement kilns there is considerable increase in production and reduced fuel consumption by using the mechanical draft and in pottery kilns, working on continuous kilns burning ceramic, there is great improvement in temperature regulation and the operation of the kilns is made easier. For melting furnaces there is increased temperature, reduced melting period and considerable increase in production by using the induced draft system as well as for reheating furnaces, such as are used in a large number of iron and steel works.

COTTON CLOTH FOR AIRCRAFT

By M. M.

The cotton trade presents many war features. One of the most interesting —and one that is often overlooked—is the provision of cloth for use in the building of aircraft, more particularly of aeroplanes. In this direction the trade has afforded most valuable help to the Allies. In pre-war days the making of aeroplanes fabrics had secured a solid footing in Lancashire, and the government exercised a wise discretion, soon after hostilities began, in acquiring control of the whole output and preventing leakage to the enemy. But pre-war production was far from sufficient to meet war needs, and in the last two years there has been a considerable development in the making of fabrics that aeroplane building has asked for. More spindles and more looms have been set to work. Some of the best known and the biggest of the fine spinning concerns are wholly devoted to turning out the yarns, which are spun from high-grade Egyptian and from Sea Island cotton. To make this supply of cotton certain was one of the subjects which the government had in view in deciding to take over the whole of the next crop of Egyptian cotton, a step which had received unanimous approval of the trade.

In application of fine and strong textile to the covering of aeroplane wings cotton has been running a sort of race with linen. There is no doubt that the use of linen, in the past at any rate, has presented some advantages over the use of cotton cloth. Linen is stronger, and has a smoother surface. On the other hand it is heavier, usually weighing 4 oz. per yard as against 3¼ oz. in the case of cotton, an important consideration. One objection to cotton has been that the surface being less smooth than that of linen, there is some interference with the proper application of dope. As to the comparative strength of the two fabrics, one would suppose that cotton cloth, which will stand a strain of 1½ tons per square yard, would meet all demands that are ever likely to be made upon it. However there is no finality in sight in the design and manufacture of cotton fabrics. No one feels more strongly than manufacturers that we have not yet sounded the possibilities of cloth. The more the staple is examined and tested scientifically, the more wonderful does it appear, and the more clearly is it recognized, that the end is not yet. So far, the twin sciences of spinning and weaving in practice have kept fairly level with the demands of the public, but further progress will be made, and it is not too much to hope that cotton cloth will be produced which for aircraft purposes will be of unapproachable excellence and suitability.

At the present time experiments are being carried out with the object of eliminating faults and defects, such as they are, and of providing, a fabric which shall fully satisfy the needs of the aircraft industry. Designers of aeroplanes have laid down certain requirements and the cotton trade is endeavouring to meet them. It must be remarked in this connection that, as the aircraft industry has grown, its needs in the way of essential materials have grown with it and have become more exacting. The chief objects now aimed at are still greater strength and durability, and still greater powers of resistance to wind pressure, with an absolutely smooth and even surface that will not be too absorbent of dope. All this has to be accomplished without any sacrifice of lightness, and without any considerable reduction in the element of elasticity. We have every confidence that the response of the cotton trade will be of the most satisfactory character, and that the aeroplane cotton fabrics of the future will be worthy of a great industry which in the past has scored many triumphs.

FLINT AND TINDER AGAIN

The manufacture of tinder-box flints is booming just now owing to the match shortage.

This is probably the oldest handicraft in Britain—older, in fact, it could hardly be, for it forms an industrial link—the only one—with the prehistoric Stone Age.

The centre of the industry is the little village of Brandon, on the borders of Norfolk and Suffolk. The men who pursue it are known locally as flint-knappers, and the work is done in little sheds, often situated at the back of the cottages in which the workers live.

In pre-war days the demand for the flints they produced came chiefly from Spain and Italy, in the rural areas of which countries the old-fashioned flint-and-steel tinder-box has never been wholly supplanted by the modern match. But nowadays practically the entire supply is eagerly snapped up by the makers of those ingenious little mechanical devices for lighting pipes and cigarettes with which the war has rendered us familiar.

It has been found possible mechanically to work tungsten containing a considerable amount of tungsten carbide when the carbide was made separately, powdered, and added to the tungsten powder before pressing. Tungsten ingots containing tungsten carbide made up in this manner may be mechanically worked when the carbon content is far in excess of that necessary to make the tungsten brittle ordinarily. When added in this way the tungsten carbide does not surround the tungsten grains.

Engineer's Life Not a Bed of Roses When Things Go Wrong

Poorly Designed Plant Adds Greatly to the Labors of the Engineer, and is a Source of Constant Worry and Danger in Operation

By S. BALMFIRTH

IT does not often fall to the lot of the man in overalls to have occasion to amend or remodel the work of the consulting engineer but in the writer's case it was necessary to change over much of the plant over which he took charge in October, 1913.

This plant, furnishing the power requirements of a large hospital, had three 200 h.p. B. & W. boilers with chain grate stokers, Blake and Knowles feed pumps, vacuum pumps and bilge pumps in the boiler and pump rooms. Three Goldie-McCulloch vertical high speed engines were directly connected to Swedish General Electric generators of 120, 100 and 25 k.w. capacity, all capable of being operated at 25 per cent. overload. There was also installed a twelve-ton C O 2 refrigerating and ice making plant with refrigerators scattered all over the buildings.

Boiler Room

It will be difficult to describe the plant so as to enable the reader to visualize the conditions that were imposed upon the operating staff. To begin with, the boiler room was only 28 ft. wide, and three B. & W. boilers were placed in that space. This left a passage between the single boiler and the double battery 3 3 ins. wide and a passage 26 ins. wide between the second boiler of the battery and the wall of the building. Of this second passage, half was taken up with steam and other service pipes, so that in passing from the front to the rear of the boilers, one had to turn side-wise and even then, one rubbed his shoulders on the pipes and his nose on the brickwork of the boiler. Those who have had to do with B. & W. chain grate stokers will understand the difficulties attending the care of these stokers. It was not possible to open the side door half way, so that the work of replacing ashplates whilst the boiler was in service was a task to be dreaded.

The heat radiated from the boiler setting was so great, that the cork insulation on the circulation and suction piping of the refrigeration plant (which ran through this passage) actually caught fire on several occasions, and about six or eight feet were burned off. The beams carrying the boiler room ceiling were only eighteen inches above the tops of the boiler drums, so that there was less than three feet of room for men to work in on the boiler tops and the engineers were constantly receiving burns of a more or less serious nature. The constant temperature over the boiler tops varied from 145° to 155° F. If one tried to open a valve on the boiler tops barehanded, he left the skin of his hand on the valve wheel, the writer speaks feelingly on this subject.

To operate the stokers, a 4x5 vertical engine was installed, but when the writer took charge one boiler was under steam and had been for some time and the engine was pounding like a steam hammer and as this engine was the only means of driving the stokers provided, the only way of taking up lost motion on the brasses, or to do anything else was to get up steam, and fill the boiler with water, when the engine might be stopped, and any necessary work done before the steam ran down again (perhaps).

The boiler fronts were about 14 ft. 6 ins. in from the south wall of the boiler room and as the boiler tubes are eighteen feet long it will be seen tha' replacing boiler tubes was an interesting job to say the least. There were windows in the wall, but they were not the full width of the boilers, neiher were they in line with the boilers. Holes have had to be cut in the wall in order to replace tubes.

Pump Room

As shown in the plans, the pump room was directly in front of the boilers under the engine room floor. The ceiling was about eight feet high. As before mentioned this room contained two feed pumps, one vacuum pump, sump tank and pump, and also a Cochrane heater. The feed pumps were placed on the same level as the heater, with the water cylinder heads not more than two feet away from the wall, and when it was necessary to pack the pumps, which was very frequent at first on account of the amount of sand in the water, the man doing the job had to sit on the suction pipe, which ran along the floor between the pumps and the wall, with his neck against the high pressure drip pipe which discharged into the Cochrane heater. As may be imagined there were all kinds of pump troubles, especially at peak load, when the pumps frequently lost water, due to the high temperature of the water and the lack of suction head.

The sump was covered with a cast iron plate which carried a submerged centrifugal pump motor driven. The motor burned out about every two weeks until it finally gave up the ghost entirely. The pump was handling hot water in quantities, the motor was of th enclosed type, with practically no ventilation, standing on a hot plate, in a temperature of 145°.

The vacuum pump discharged into the feed heater and all the exhaust steam went through the heater, so that all the air drawn from the heating system, was mixed with the steam and carried round the building again. This in the writer's opinion was one of most prolific causes of the troubles which cropped up from time to time.

An oil separator was placed in the low pressure main, between the heater and the heating system (to keep the oil out of the heating system, the boilers did not matter).

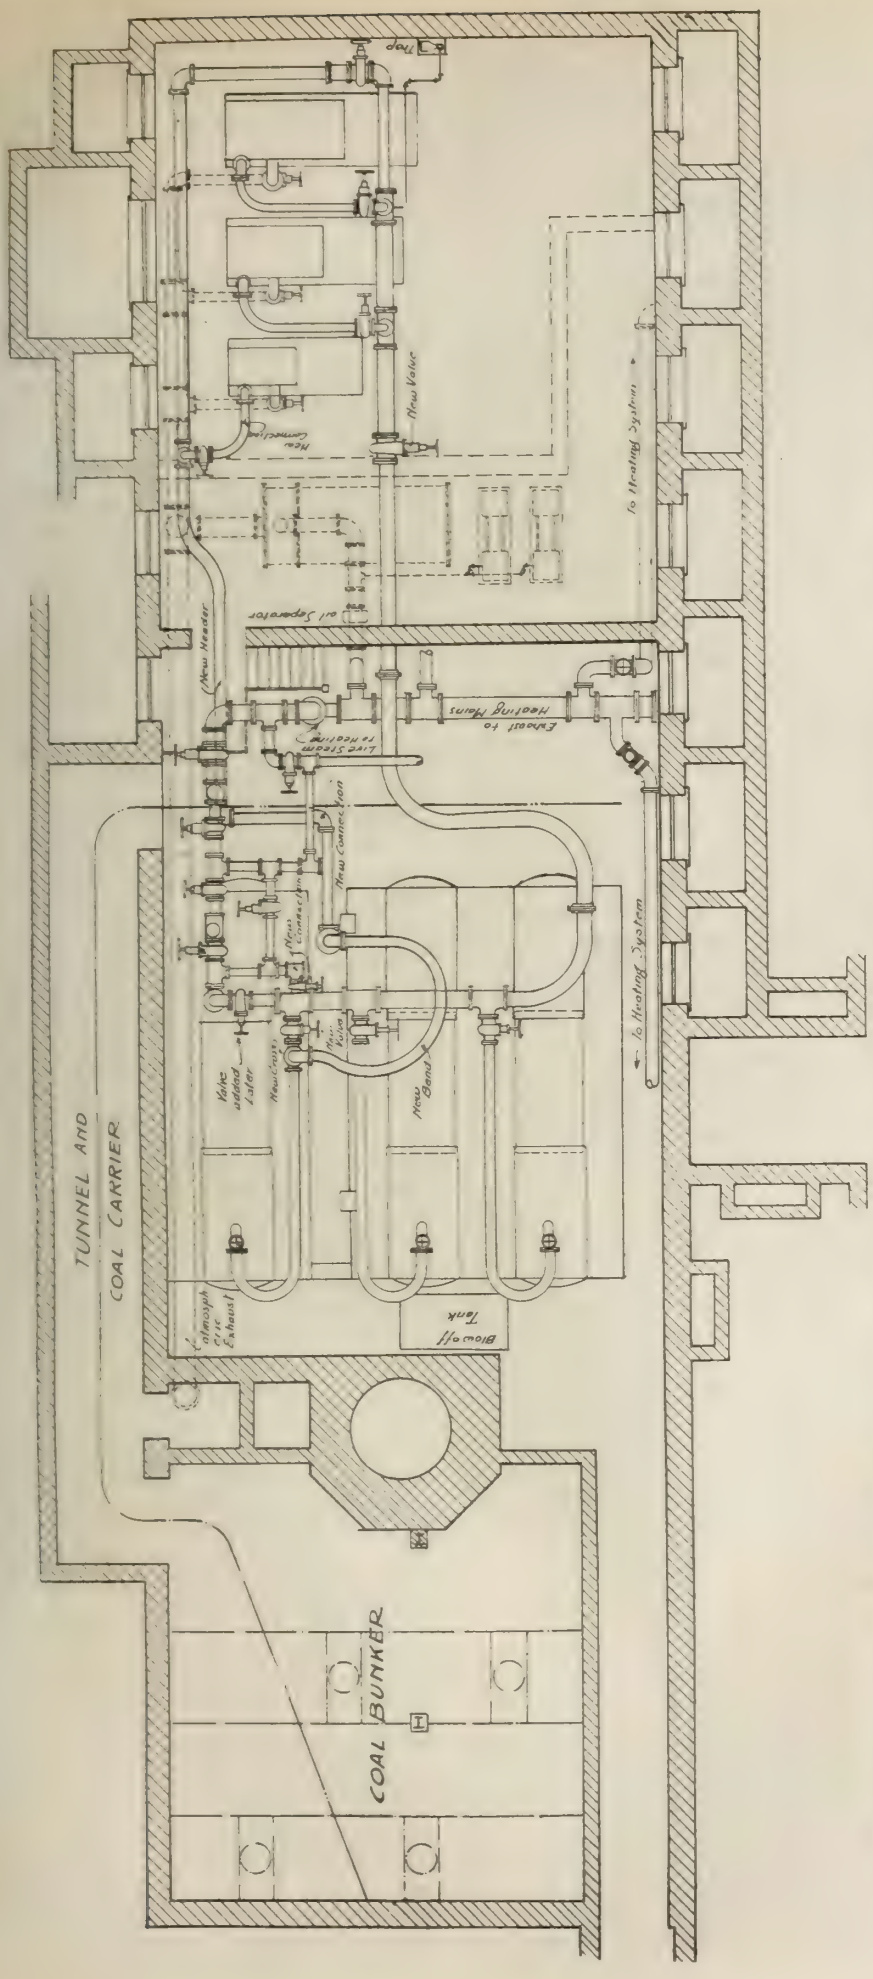
There was an atmospheric vent to the heater, but as the high pressure returns created steam pressure in the heater the vent was useless, as it only allowed steam to blow away as well as air. There was no means of closing off the steam from the heater, except its own interior valves, and as the plans did not include a stop valve in the discharge pipe between the vacuum pump and heater, it was impossible to work on either without a complete shut down, although later a valve was installed on the vacuum pump discharge. The outboard exhaust pipe ran along the top of No. 1 boiler setting and passed over the flue at the rear of the boilers, and was provided with a Swar exhaust head.

The back pressure valve had been installed wrongly and did not seat, but it was impossible to alter it, because there was no means of shutting the steam off from it. It was eventually set right by running the small engine, and opening the heating systems on the three buildings, then breaking a joint and dropping in a blank flange of sheet steel, but the job nearly put three men out of business before it was done with the heat and escaping steam.

Bunker Arrangement

The coal was brought to the boilers in a bucket carried on an I beam, with a one-ton Yale and Towne trolley hoist, from a bunker in the rear of the boiler room. The floor of the bunker was about three feet lower than the passage which connected boiler room and bunker and about four feet below the level of the stoker hoppers. So that the firemen had to jump down about three feet, or if the bunker were full, dig down that distance, and then raise the full bucket which weighed about 1300 lbs. from four to five feet, to be able to push it, and then climb out of the bunker.

The ash handling system as installed was unique. The ashes had to be pulled forward from the back of the ashpit, shovelled out on to the floor, (the pits being about two feet deep), and shovelled into cans. The cans were hoisted up about seven feet on the coal hoist,



LAYOUT OF PLANT SHOWING COAL BUNKERS, BOILER ROOM AND ENGINE ROOM. FEED WATER HEATER AND PUMPS SHOWN DOTTED UNDER ENGINE ROOM.

run on the trolley to the hydraulic lift, rolled on to and then off the lift, at the ground level, and then dumped. In all, the ashes were handled some six or seven times by the firemen, who sometimes would have from twelve to fifteen cans to take out on each shift. Imagine this in zero weather.

The firing floor was ventilated by means of a motor driven supply fan on the roof of the power house. The air was washed by a Carriere air washer. This was one of the best features of the whole installation. There were three ducts supplying the firing floor, each about 24 ins. diameter so that the firing floor itself was fairly cool. There was also an exhaust fan to remove the hot air. The supply ducts in front of the boilers in addition to the other piping took up so much room that although there was a gallery across the boiler-room, between the drums and tube doors, it was impossible to walk upright in it, one had to go on hands and knees.

There was only one steam main, and only a single feed pipe for the three boilers, and not a single valve on the feed line between the boiled feed stop-valve and the discharge valve on the pumps, so that if it were necessary at any time to pack a feed stop-valve, the pump had to be stopped.

High Pressure Piping

Similarly, if any main stop-valve on the boilers were to be packed, all the boilers had to be shut down. There was only one valve on each boiler, and that a gate valve and no non-return valve. It was not thought necessary either to provide any escape pipe for the safety valves, so that every time they blew, the boiler room was filled with steam incidentally making the place hotter.

The steam main to the engines was 8 in. to supply in all 275 H.P. The engines had stop-valves, respectively 3½ in., 3½ in. x 2½ in. so that the pipe was about two sizes too large. It was drained by a 2 in. Bundy trap, discharging to the feed water heater. Every time it discharged, it blew all the water out of the heater up the outboard exhaust, and kept the firemen guessing where the water had gone to. Incidentally it upset the plates which retained the filtering medium, coke, in place, and for a week the writer did nothing but take that pair of pumps apart and put them together again, getting out the coke. The separator drips on the engines, we piped to another two-inch Bundy trap which discharged to the sewer, just why is not known. The oil separator on the exhaust line was dripped to a ¾ in. Bundy lifting trap, needless to say this trap would never work.

There were other things about the plant that were not just according to Hoyle, one of them being that the C O2 compressor was belt-driven from a 20 H.P. motor, set so close to the floor as as to pick up any dirt or anything else, if the belt got the least slack. The reader can see from what has been de-

scribed what the writer had to contend with, and this in a plant in which continuous service is imperative, in which a shut-down without notice might mean the death of a patient.

Anyone can see from this description that serious trouble was inevitable. In In fact trouble did begin in about 18 months. The steam piping began giving trouble by leaking at the threads, both high and low pressure systems being affected. In the writer's opinion this was caused mostly by the air being carried over with the steam, (through the low pressure system especially) and never being got rid of,which corroded the piping, as it is well known that moisture in presence of air, will rust iron more quickly than if entirely submerged.

Alterations.

Things ran on for about two years when the writer obtained permission to install an auxiliary steam main and a duplicate feed line, and drew up plans for the same.

These were submitted to the boiler inspection department and after examination of the same, it was decided by the chief boiler inspector, to inspect the plant, as the department had no records of it. This was done, and the inspector's report was far from complimentary or comforting. The installation of the new lines was sanctioned, including non return valves, if the writer could find room to get them in. However, before the whole of the alteration could be carried out, more trouble developed and the management decided to remodel the whole boiler plant, in accordance with the suggestions of the writer, who was instructed to draw up the necessary plans.

The work to be done was—to build a new fire room to the east of the existing boiler-room to cut the boilers down, turn them at right angles to existing position, lower the whole three boilers five feet, rebuild them, and reconstruct all service mains. These included steam for engines, steam for laundry, cooking, sterilizing; also steam for dairy and operating room use, heating mains, refrigerating pipe lines; also hot and cold water service pipes, and some electric lighting cables.

Whilst this was being done it was necessary to operate the plant to give service twenty-four hours daily. This has been done, although to be exact the last sentence has not been carried out to the letter. In all the interruptions to service have amounted to about 48 hours during the alteration, these suspensions of service having been arranged for so as to cause the least amount of inconvenience.

REGULATIONS FOR DEALERS IN COAL

Regulations regarding the importation, sale and delivery of coal have been issued by the Fuel Controller. Among other things they require that every coal dealer shall post in a prominent place in his office a conspicuous typewritten or printed notice containing a list of prevailing retail prices of all classes and sizes of coal handled by him, including discounts, if any. In calculating overhead charges to determine the price of coal, dealers are required to exercise moderation in the amount they include as their own salaries. In this connection the regulations state, "Salaries and expenses to officers or partners are not to be increased over those prevailing during the year 1914 at a greater rate than salaries in other lines have increased. A dealer may charge his business with his own salary but a reasonable rate only."

Dealers conducting a retail as well as a wholesale business are required to apportion their overhead expenses and fixed charges to each branch, and this apportionment must bear reasonable comparison with the average overhead expenses and fixed charges of dealers who are engaged entirely in retail or entirely in a wholesale business.

A VAST NEW OIL SOURCE

The oil shortage brings into prominence a hitherto neglected source of oil in the form of "oil shale," an organic-matter bearing clay formation, which, when crushed and treated with superheated steam, yields crude oil and sulphate of ammonia. The prospective development of the huge deposits of oil shale is one of the reasons for the oil land leasing bill now before Congress.

Shale occurs in widespread, thin beds which were formerly sea bottom. These beds are deposits of the clayey matter carried by rivers—clayey matter which, being finely broken up, does not sink readily to the bottom, but after being emptied into the ocean is carried by the current and spread over wide areas. One of the characteristic traits of shale formation is that it very readily breaks into thin layers.

Shale is oil yielding, but not oil bearing. Upon treatment with super-heated steam a chemical reaction takes place which yields crude oil. It must be mined like coal, and at about the same price, so that even with an extensive production of oil from shale there will be no great reduction in the price of oil.

Prof. Russell D. George, State geologist of Colorado, recently said that in two counties of Colorado there was enough shale to make "ten times as much oil as has been produced in the United States since the discovery of oil in 1859."

OILS AND THEIR USES

By M. M.

EVERYONE knows scomething about the usefulness of oils in the workshop, but there are a great many who employ them indiscriminately, thereby making more or less serious mistakes. A little general understanding and commonsense is necessary, and also a little discernment as to the nature of the oils which are useful in everyday use. A very common mistake is to oil a sewing machine, bicycle, pram or clock with any kind of oil which happens to be handy. Frequently these are oiled too often and yet again they are oiled too seldom, being left till they squeak. Then they are given too much oil, often of the wrong sort, and then there is more trouble. The right oil to use for a clock, no matter what sort it is, is clock oil, which is a clean, thin lubricating oil that does not dry or get sticky. It is also suitable for any light machinery. The least possible touch of oil on the working parts only of clocks will suffice, and as the movements are slow, they do not need it often. Now if this oil were used for sewing machines and the like, they would require it too often, so a machine oil with more body is best used very lightly, but as frequently as may be needed to keep all the parts slightly greased. Fast-running machinery requires oiling the oftenest. Whereas once a year might do for a clock, once a day would be necessary for a machine in constant use. And the heavier the machinery the heavier the oil should be; engine oil is really heavy machine oil.

Linseed oil, in appearance, might seem to be a good lubricant; but it is altogether unsuitable. It dries like a hard varnish, and, of course, would clog any machinery almost as badly as varnish would, except that it hardens slowly. If a piece of rag that has been used in apers oil, and another wet with linseed oil, be left exposed to dry air for a considerable time, the former will be still the same, but the latter will have become stiff and heavy. For this reason it is quite unfit for using on hones and whetstones when sharpening tools, for it makes them hard and useless, but it is always around woodworking shops, and thus many workmen have spoilt their stones before finding the reason out. If used for oiling the bright blades of saws or other tools, it makes them brown and varnishy. But linseed oil is the very best for rubbing into the wood parts of tools to keep them clean, and it imparts a hard, finished surface. For woodworking and polishing it is invaluable; also, in the manufacture of varnishes, oilcloths and imitation leathers. Boiled linseed oil is the only kind for mixing paint; or it would never dry. It is also essential for making putty; the best is made from raw linseed oil and whiting. Very often cotton-seed oil is used as a substitute for linseed oil but is a very poor substitute. Linseed oil is useful for domestic purposes in reviving varnished furniture and leather goods. It is sometimes employed for machine belting, but castor oil is considered best for the purpose, also for the leather of bellows and such like articles, where suppleness and durability are required. As it is expensive, however, palm oil makes a good substitute.

Petroleum or paraffin, besides being the recognized burning oil for lighting and heating purposes, is excellent and cheap for cleaning the working parts of machinery before lubricating. It is good for thinning down machine oil before lubricating and makes a capital lubricant for locks and light machinery, if a little sperm oil is added.

Power Plant Management and the Selection of Coal

The Proper Selection of Coal Suitable For the Conditions Under Which it is Burned is Essential in the Economical Operation of the Power Plant—The Present Article, the Second of a Series, Deals With This Phase of Power Plant Operation

By ROBERT JUNE

POWER will win the war. Coal is the source of power. Every cartridge, every rifle, shell, field-gun, motor truck, aeroplane, merchant vessel, destroyer, and dreadnought, requires a given quantity of coal for its production. Our available supplies of coal are definitely limited by mining and transportation conditions. If we waste coal at any point where it can be saved, our effective power on the battlefield is inevitably lessened. Probably no single factor in the operation of an existing power plant, or the design of a proposed plant, offers such opportunities to effect economies as does the proper selection of coal—the adoption of the right fuel to the right equipment.

Classification of Coals

Ninety-five per cent. of the coal used in steam production falls in one of the four following classifications:—

Anthacite Coal consists almost entirely of carbon and inorganic matter; it contains little, if any, hydrocarbon. Some varieties approach graphite in their characteristics and are burned with difficulty, unless mixed with other coals.

FIG. 1.

Good anthracite is hard, compact and lustrous, and gives a vitreous fracture when broken. It burns with very little flame, unless moist, and gives a very intense fire, free from smoke. As it is only available for steaming purposes in certain limited sections of the country, specific problems relating to its combustion will not be discussed, attention only being called to a principal objection to its use, that is, no matter how carefully handled, it is liable to break up under the influence of the high temperature of the furnace when freely fired, with consequent large losses of fine pieces through the grates to the ash pit. It must also be remembered that it requires at least 40 per cent. greater combustion space than does bituminous coal. On this account it should never be purchased for use in furnaces not designed for it.

Dry Bituminous Coals are the best of the bituminous variety for steaming purposes. They are hard and dense, black in color, but somewhat brittle and splintery. They ignite readily, burn freely with a clean bluish flame and without caking.

Bituminous Caking Coals swell up, become pasty and fuse together in burning. They contain less fixed carbon and more volatile matter than the free-burning grades. Caking coals are rich in hydrocarbon and are particularly adapted to gas making. The flame is of a yellowish color.

Long Flaming Bituminous Coals have a strong tendency to produce smoke. Some varieties cake, others do not, while burning. This coal is preferable for use under pans, dryers, in cement kilns, etc., rather than for general steam making purposes.

As a general proposition, the free-burning, dry bituminous coals of the West Virginia, Pittsburgh and Illinois districts are to be selected for the production of steam.

The Question of Size

The selection of coal of a certain classification is not enough. The size of the coal influences the capacity of the boiler owing to its effect on draft. With poor draft, fine coal cannot be burned in sufficient quantities to maintain the rated capacity. If thin fires are resorted to, the efficiency of the boiler is usually lowered by holes in the fire. Dust and very fine coal check the air flow or else pass up the stack unburned. Experience alone will show the size of coal best suited to individual operating conditions. After you have determined the proper size of coal, you should insist that all deliveries conform to this uniform size, particularly since coal of uniform size does not pack so badly as coal of mixed sizes.

Bituminous coals in the Eastern States are graded and sized as follows:—

A.—Run of mine coal; the unscreened coal taken from the mine after the impurities, which can be practically separated, have been removed.

B.—Lump coal; that which passes over a bar-screen with openings 1¼-inch wide.

C.—Nut coal; that which passes through a bar-screen with 1¼-inch openings and over one with ¾-inch openings.

D.—Slack coal; that which passes through a bar-screen with ¾-inch openings.

Bituminous coals in the Western States are graded and sized as follows:—

E.—Run of coal; the unscreened coal taken from the mine.

F.—Lump coal; divided into 6-inch, 3-inch and 1¼-inch lump, according to the diameter of the circular openings over which the respective grades pass; also 6 by 3 lump, and 3 by 1¼ lump, according as the coal passes through a circular opening having the diameter of the largest figure and over one of the smaller diameter.

G.—Nut coal; divided in 3-inch steam nut, which passes through an opening 3 inches in diameter and over 1¼-inch; 1¼-inch nut which passes through a 1¼-inch diameter opening and over a ¾-inch diameter opening; and ¾-inch nut, which passes through a ¾-inch diameter opening and over a ⅝-inch diameter opening.

H.—Screenings; that which passes through 1¼-inch diameter opening.

For maximum efficiency, coal should be uniform in size. As a rule, the percentage of ash increases as the size of coal decreases. This is due to the fact that all of the fine foreign matter separated from larger coal, or which comes from the roof or the floor of the

mine, naturally finds its way into the smaller coal. The influence of the size of screenings on the capacity and efficiency of a boiler in a specific case is illustrated in Fig. 1. The curves are plotted from a series of tests conducted with Illinois screenings on a 500 H.P. B. & W. boiler, equipped with chain grates, at the power house of the Commonwealth Edison Company.

Relation of Composition of Coal to the Size of Combustion Space

Coal must be adapted to the combustion space in your furnaces, or your furnaces must be adapted to the coal, if you are to avoid waste. As the chemical composition of the coal enters into this problem, I include Table 1.

Coals of different composition require different sizes of combustion space. The chemical characteristics that are most likely to affect the size of the combustion space required for a given set of conditions are the quantity and quality of the volatile matter. The quantity of the volatile matter is shown by its percentage as determined by the proximate analysis. The quality of the volatile matter is indicated approximately by the ratio of volatile carbon to available hydrogen, and also by the oxygen content of the coal on a moisture and ash free basis.

The principle chemical characteristics of Pochahontas (Bituminous Caking), Pittsburgh and Illinois coal are given in Table II.

Table III. gives the size of the required combustion space for the three coals and several sets of conditions, indicated by columns 1, 2, and 3.

Roughly speaking, under the same conditions, Pittsburgh coal requires about 20 per cent. larger combustion space than Pocahontas coal, whereas Illinois coal requires about 40 per cent. larger combustion space than Pittsburgh coal.

That the size of the combustion space does not increase in direct proportion to the percentage of volatile matter in the coal is shown graphically in Fig. 2.

Both Figs. 2 and 3 are plotted from data given in Table III. The curve of the upper group of Fig. 3 gives the relation between the size of combustion space and the product of quantity times the quality of volatile matter for one degree of completeness of combustion indicated by the figure near each curve. For complete combustion, it may be said that the size of the combustion space varies directly as the product of the quantity and quality of the volatile matter, as given in Table III.

If you want to know whether or not you are burning coal of the right composition, measure up the combustion space in your furnaces, then have a detailed chemical analysis made of a fair sample of your coal, and check them against the data given herein. If you contemplate a new power plant be sure that combustion space is designed for the coal which you can buy to best advantage.

Influence of Moisture

Moisture in coal reduces the steaming efficiency. One per cent. of moisture means a loss of thirteen BTU per pound of coal in superheated vapor in the smoke gases. It also decreases the capacity of the furnace, due to lowering the rate of combustion.

Although moisture is a great and uncertain variable, and the producer can exercise no control over this factor, still the purchaser should protect himself against excessive moisture by stipulating an amount consistent with the average inherent moisture in the coal, and proper penalty should be fixed for delivery in excess of the amount allowed, a corresponding bonus being paid for delivery of less than contract amount.

TABLE I.

Class of Coal	Fixed Carbon	Volatile Matter	Heating value per lb. of Combustible

The Ash Problem

The amount of earthy matter or ash is of considerable importance in fixing the heating value of the coal since the heating value of the combustible is practically constant. The effect of ash on the heating value of Illinois screenings as fixed under a B. & W. boiler with chain grate is shown in Fig. 4. This value varies with the different types of boilers, grates and furnaces, but is substantially as illustrated. The amount of refuse in the ash pit is always in excess of the earthy matter as reported by analysis, except where the amount carried beyond the bridge wall is very large.

The maximum allowable amount of sulphur is sometimes specified, since some grades of coal high in sulphur cause considerable clinkering. But sulphur is not always an indication of clinker-producing ash, and a more rational procedure would be to classify a coal as clinkering or non-clinkering, according to its behavior in the particular furnace in question, irrespective of the amount of sulphur content. Ash fuses between 2,300 and 1,500 deg. Fahr. and of the formation of objectionable clinker is to be avoided, the furnace must be operated at temperatures below the fusing temperature. Several large concerns insert an "ash fusibility" clause in their coal specifications.

FIG. 3—RELATION BETWEEN SIZE OF COMBUSTION REQUIRED AND CHEMICAL PROPERTIES OF THREE COALS. SMALL FIGURES, ETC. (SAME AS FIG. 2).

At present the ash problem is accentuated by the delivery of "dirty" coal. We find from reliable sources that the coal received in many of the largest power plants has increased by 5 to 10 per cent. in ash and has decreased in heating value by 8 to 12 per cent. Many good authorities state that the amount of coal consumed in their plants has increased 10 per cent. due entirely to the inferior quality of coal received to-day as compared with that received two years ago.

There is no excuse for this "dirty" coal. The railroads during the past year, have been burdened hauling 30,000,000 tons of worthless dirt that anyone can dig up from the back-door yard or have from rock-pile for the asking. These 30,000,000 tons of dirt have not only cost the power plant operator $120,000.000, but they have deprived him of 30.000,000 tons of real coal. The remedy for this condition is to be found in determined individual and co-operative insistence upon clean coal, and in the establishment of government coal-sampling stations to check the product of each mine as to quality and effectiveness of preparation.

Heating Value of Coal

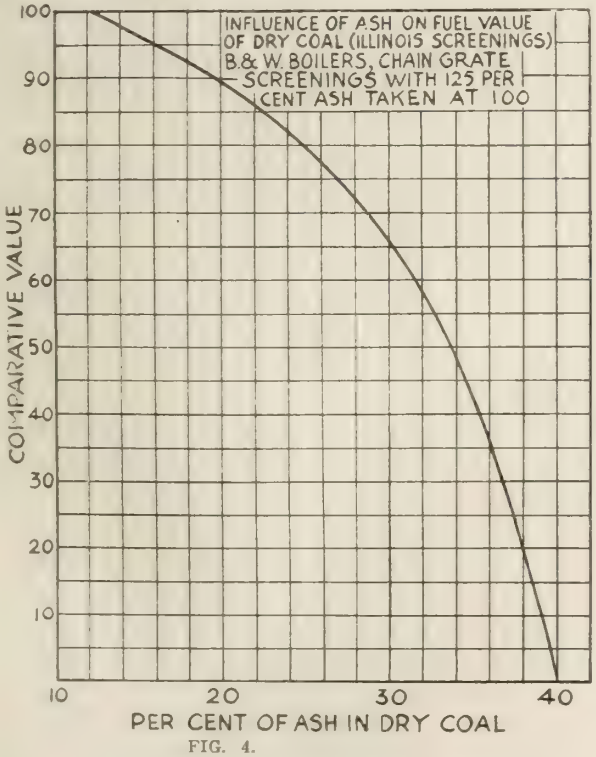
I have purposely left discussion of the heating value of the coal till last, as this is the most obvious of all the factors entering into its selection.

The heating value of coal as determined by a sample burned in an atmosphere of oxygen does not give its absolute commercial evaporative power, since this depends largely upon the composition of the fuel, character of grade, and conditions of operation, as already outlined. In large plants where a number of grades of fuel are available, it is customary to conduct a series of tests with the different grades and sizes, and the one which evaporates the most water for a given sum of money, other conditions permitting, is the one usually contracted for. In designing a new plant particular attention should be paid to the performance of similar plants in operation, and the fuel and stoker should be selected which are found to give the best returns for the money.

However, there is no reason why the power plant operator should not know the number of B.T.U. in the coal which he puts into his furnace and every reason why he should know. The evaporation of so many pounds of water per pound of dry coal does not in and of itself indicate efficiency. The equivalent evaporation of 8 pounds of water per pound of dry coal would represent 70½ per cent. efficiency, if the coal contained 11,000 B.T.U. per pound, but the same evaporation with a coal of 14,400 B.T.U. heating value would represent only 53¼ per cent. efficiency. Therefore analysis of the heat units in the coal is essential to a knowledge of its value.

Purchase of Coal Under Specifications

Engineers differ as to the specifications to be used in purchasing coal. Some favor a system of bonus and penalty on ash basis only; others favor a similar system on B.T.U. basis only. Much can be said on both sides, but undoubtedly the safest system is a combination of the two. With such a system a proposal is made by the contractor, stating price, B.T.U. and ash content. Samples are taken each day of the coal furnished and a bonus is paid for B.T.U. content exceeding contract stipulation, the bonus being the same percentage of contract price that the excess B.T.U. is of the specification value. A corresponding deduction is made for coal falling below the specifications and in some cases a lower limit is set below which the coal may be refused at the purchaser's option, with the further stipulation that continued failure to supply coal within the specification limits will forfeit contract.



INFLUENCE OF ASH ON FUEL VALUE OF DRY COAL (ILLINOIS SCREENINGS) B.& W. BOILERS, CHAIN GRATE SCREENINGS WITH 12.5 PER CENT ASH TAKEN AT 100
COMPARATIVE VALUE
PER CENT OF ASH IN DRY COAL

FIG. 4.

For each per cent. which ash falls below analysis a bonus is allowed. Generally an increase of 2 per cent. increase in ash content is allowed without penalty, above 2 per cent. a penalty is deducted according to a sliding scale.

You can only be sure you are buying your coal right by making an analysis of it as delivered. Two carloads of coal may look the same, but may vary 10 per cent. or more in B.T.U. and a difference of 10 per cent. makes a difference of from 8 to 10 per cent. in the value of the coal.

If you are not in a position to make an analysis of the coal yourself, all you have to do is to put an empty barrel in your boiler room and have your fireman throw a part of a shovel of coal in it four or five times a day. At the end of a week or a month you can take this coal out, mix it thoroughly, quarter it, mix it again and quarter it until you reduce it to a size suitable to forward to the nearest testing laboratory. By mixing it, you will have a representative sample which will indicate pretty accurately the grade of coal you have been burning and from which you can determine the efficiency of your boilers.

In entering upon a contract, remember that the important items to be considered in the specifications are:-

A.—A statement of the amount and character of the coal desired.

B.—Conditions for delivery.

C.—Disposition to be made of the coal in case it is outside the limits specified.

D.—Correction in price for variation in heating value and in moisture and ash content.

E.—Method of sampling.

F.—By whom analyses are to be made.

In conclusion, it is not easy to select the proper coal for any given plant but there is no factor in power plant operation which will so well repay proper attention.

Ingersoll, Ont.—A $60,000 extension to the present plant of the Ingersoll Machine Co. is contemplated.

Switch Gear Standardization: Necessity and Advantages II.

The Problem of the Standardization of Equipment is Receiving World-wide Attention and it is a Well-recognized Fact That if a Country Wishes to Maintain its Position in the Engineering Markets of the Future Standardization of Equipment Will Become Necessary

By C. C. GARRARD

Air-Break Circuit Breakers

IN circuit breakers, brush contacts are usually used at considerably higher contact surface-density than with the jaws of knife switches. A separate standard of specific pressure drop of brush contacts is therefore required. The values given in Fig. 9 are put forward as a basis of discussion. They represent results which can be obtained by reasonably good work and which do not result in temperature rises above those suggested on page 12. A standard of breaking capacity also should be fixed analogous to that discussed under cut-outs and oil switches.

Cut-Outs

While the standardization of cut-outs has been carried out to a considerable extent in other countries, with us practically nothing has been done. This is not to say that the subject has not been worked at. Numerous researches and papers have been published. The engineering standards committee announce, however, in their 1917 report, the forthcoming issue of a specification for fuses for use on ships. It is to be hoped that this will be followed at no distant date by the others which are urgently needed in the interests of the industry.

One of the evils which the manufacturers of this class of article suffer under is that cut-outs have been considered as peculiarly fit subjects for special designs on the part of their users. In this, electric supply engineers have often followed the example of waterworks and gasworks engineers in similar circumstances.

The author was informed recently by a manufacturer in the Midlands that his firm alone made over 300 different patterns of ¾-in. main gas-cocks.

Many electric supply authorities issue their own specifications for house service cut-outs, necessitating special drawings, patterns, and tools. The same remarks apply to house-service cable boxes, main switches, and the like. It is perhaps too much to hope that all this can be swept away, within a reasonable time, simply by the issue of specifications by the engineering standards committee. An energetic propaganda among the responsible parties will be necessary to secure the desired results. These could best be obtained probably if supply engineers could be induced to take the matter up themselves with the object of securing uniformity as regards house-service fittings.

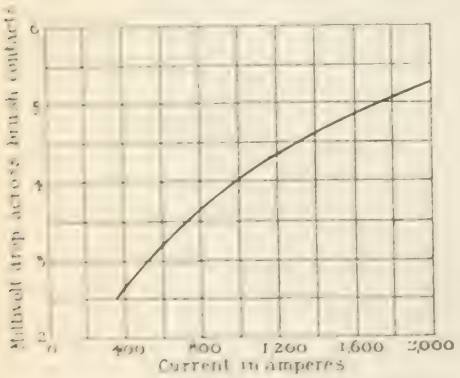


FIG. 8—MILLIVOLT DROP ACROSS BRUSH CONTACTS.

National Electric Code Cut-Outs

In any review of the subject of cut-out standardization, one of the first things to be considered is the enclosed cut-out standardized by the American National Electric Code. This is completely standardized as regards dimensions, and its use is practically obligatory in America as the code is the standard insisted upon by the fire insurance authorities there. The manufacture of N. E. C. enclosed cut-outs has consequently become a very important industry engaging the attention of a number of specialist firms. The general use of open and protected type cut-outs, as in this country, has been impossible in America. It is true the code contemplates open cut-outs and gives dimensions of the same. Nevertheless these appear practically never to be used. As, in spite of this, the fire hazard in this connection is not any greater with us than in the States, it cannot be said that the universal use of the relatively expensive enclosed type is justified. Nevertheless, there is a considerable field for enclosed cut-outs to meet severe conditions, and a British standard for such should be set up as well as for the protected type. As regards open-type cut-outs, the only thing about them which need be standardized is their name, as their use should be prohibited.

The short-circuit test called for in the N. E. C. enclosed cut-out is one of 10,000 amperes, independently of the size of the fuse. While this is a comparatively light test for a large cut-out (say, 400 amperes working current) it is a severe one for small currents (10 or 30 amperes) and one which many protected-type cut-outs will not pass. For very many purposes, however, such a severe test is quite unnecessary.

Short-Circuit Tests on Cut-Outs

It has been generally agreed that the severity of a short-circuit test to which a cut-out is subjected may be measured by the value of the short-circuit current which would flow if the fuse were replaced by a heavy copper connection having no appreciable resistance, the electromotive force of the supply remaining constant.

In endeavoring, therefore, to arrive at a figure for the short-circuit test to insert in a standard specification, one has to consider what short-circuit current, as

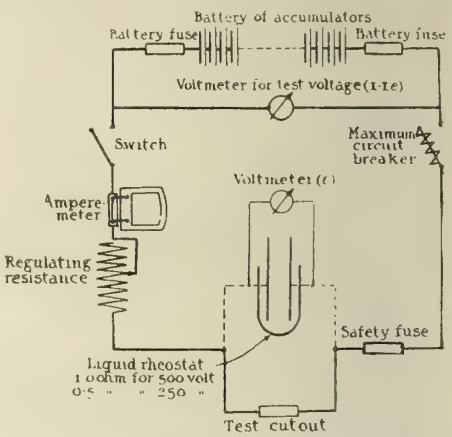

FIG. 9—STANDARD CUT-OUT TEST OF THE SWISS ELECTRO TECHNICAL SOCIETY. ELECTRIC ELEVATOR DISPATCHER.

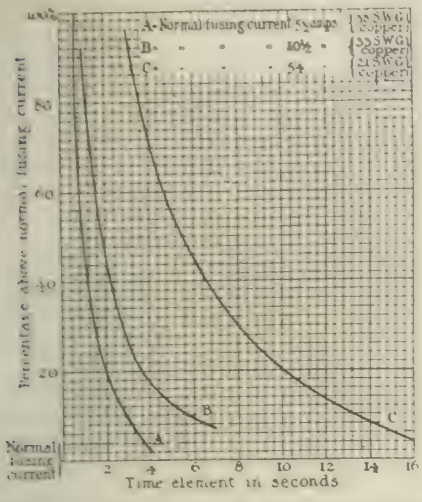
defined above, does actually flow in different situations in a supply network.

Schwartz and James in their paper laid it down that a short-circuit for main fuses and distribution boards not greater than 33 times the normal fusing current corresponds to the usual conditions met with in house-service installations. This means that for a 10-ampere working-current cut-out, having a normal fusing current of 30 amperes, the short-circuit current does not exceed approximately 1,000 amperes. This conclusion is a sound one and is borne out by practice in very many cases.

Nevertheless, with the increased size of modern distributing networks, conditions do arise which are very much more severe than those formulated above. It is easy to foresee this by calculating the short-circuit currents for small cut-outs situated at the immediate ends of short feeders having large cross-sections.

This view is also confirmed in a very interesting paper issued by the American Bureau of Standards in 1916. In order to get an idea as to the currents that might be expected under actual service conditions in case a short-circuit should occur near the customer's cut-out a number of tests were made, the results

of one series of which are given in Table 4. These tests were made in the heart of the Edison three-wire distribution system, at points varying from one to six city blocks from the nearest power house. The tests were made by connecting a resistance grid across the cut-out terminals. With the switch closed, a current



A-Normal fusing current
B- - - - 10½ -
C- - - - 54 -
Percentage above normal fusing current
Normal fusing current
Time element in seconds

PIPE TO CARRY OFF OIL EXPELLED FROM OIL SWITCH.

of about 300 amperes was taken, and at the instant of closing, the drop in volts at the cut-out was noted, and from this the current that would occur on dead short-circuit at the cut-out could be readily calculated.

TABLE 4.

Regulation Test on Continuous-current Customer's Service: Edison Three-wire System, Commonwealth Edison Company, Chicago.

Test No.	Distance to nearest Substation	Calculated Short Circuit Current
1	150	26,200
2	400	107,000
[illegible]	1,500	20,000
[illegible]	600	17,100
[illegible]	1,100	9,800
[illegible]	1,300	13,200
[illegible]	1,100	25,500
8	900	87,300
[illegible]	2,300	13,900
10	3,000	13,400
11	2,350	9,800
12	3,400	8,100
[illegible]	2,600	6,100

These tests may be taken as representative of a very large part of the Edison three-wire system in the larger cities of the States.

In view of the results given in Table 4 it might be thought at first that, to be on the safe side, all cut-outs should be specified to be capable of standing up to the very severe short-circuit conditions therein shown. This, however, would entail the use of much more expensive fittings than experience has shown in many cases to be necessary. In fact in probably the large majority of situations in this country nothing like the short-circuit conditions would exist as discovered in Chicago. The conclusion must, however, be drawn that with the increasing size of distribution networks the short-circuit conditions should be determined in the maner outlined above and cut-outs specified accordingly. It is also quite clear that a single rating as regards short-circuit would not be sufficient to cover the whole field; at least two types of cut-outs are necessary—one for heavy duty and one for lighter or ordinary duty.

Standard Method of Testing Cut-Outs

The various methods adopted by the standardizing authorities of the different countries for determining the rating (as regards short-circuit capacity) all go on the same lines, that is to say, the cut-out is short-circuited across a sufficiently large source of power with the short-circuit current limited to certain values.

Fig. 10 illustrates the test specified by the Association Suisse des Electriciens for enclosed cut-outs up to 60 amperes working current. The battery must have a voltage measured on open circuit at least 10 per cent. larger than the voltage of the cut-out being tested. The liquid rheostat of the value stated in the figure is first connected across the terminals of the cut-out (the latter not being in circuit) and the adjustable resistance arranged so that for a 250-volt cut-out a current of 500 amperes flows. It will be seen that this allows for a 10 per cent. drop at 500 amperes across the adjustable resistance which corresponds to a short-circuit current of 5,000 amperes. The test fuse is then connected instead of the liquid rheostat and must rupture the circuit without an explosion or sustaining the arc.

The principle of the German rules as regards the short-circuit test is the same as the Swiss rules except that the values are different, and in Table 5 the various figures for the different countries are tabulated.

TABLE 5.

Values of Short-circuit Current Specified by Various National Rules for the Testing of Cut-outs.

Working Amps. Current of Cut-out	Amps. Swiss	Amps. German	Amps. American	Schwartz Amps. and James
10	5,000	4,000	10,000	990
30	5,000	6,000	10,000	1,980
60	5,000	12,000	10,000	3,960
100	....	20,000	10,000	6,600

Plant Necessary When Making Short-Circuit Rating Tests on Cut-Outs

Considerable discussion has taken place as to the influence upon the severity of the test of the amount of plant connected at the time the test is made. The whole of this discussion can be clarified if we take as criterion of the severity of test the value of the short-circuit current as above defined. Naturally with a small amount of plant the short-circuit current is very limited. Again if we in any case limit the possible short-circuit current by series resistance then, provided a certain minimum of plant is exceeded, the addition of more plant makes very little, if any, difference. It is therefore only necessary to specify the minimum of plant that shall be used. It is suggested that 100 kilowatts would be sufficient for ordinary duty cut-outs and 500 kilowatts for heavy duty ones. It should be noted that these are the minimum values; more may be necessary in order to reach the short-circuit capacity when testing the larger sizes of cut-outs.

Time Element of Cut-Outs

In several of the foreign standards cut-out specifications periods of time are fixed within which the various cut-outs must operate. It is worth while to consider whether it would be advisable to include similar requirements in any British standards which may be issued.

The time taken to blow a fuse depends upon its size and the degree of overload. This is illustrated by the curves in Fig. 10. It will be seen that the times taken to melt the three fuses at the normal fusing currents were about 4 seconds, 10 seconds and 18 seconds respectively. It will also be observed that the current which gives a more or less instantaneous operation is very indeterminate, as the curves tend to rise practically vertically.

Schwartz and James suggested the following definition of "normal fusing current":—

"The minimum current required to fuse the wire in such a time interval as shall be necessary for the wire to have attained its maximum steady temperature."

This is practically the same definition as has been adopted by the National Electric Code.

The normal fusing current can best be ascertained by plotting a curve as in

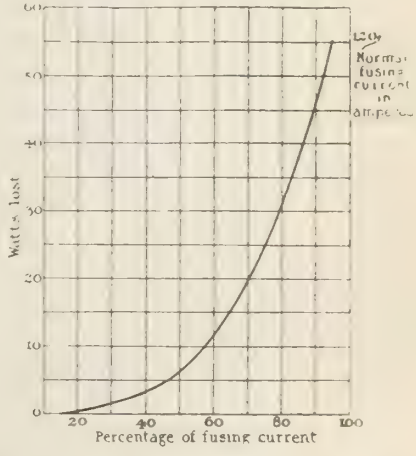


FIG. 11—CURVE FOR DETERMINING NORMAL FUSING CURRENTS OF A CUT OUT.

Fig. 11. It will be seen that the curve approaches a vertical asymptote, the value of which is the normal fusing current. If the normal fusing current be suddenly applied to the cold fuse a longer or shorter time will be required to melt the fuse depending on its size (see Fig. 10).

It follows from the above that if a definite and fixed time element be specified it would in the first place be necessary to specify value of time element for each diameter of fuse wire; secondly, it would be necessary to have different

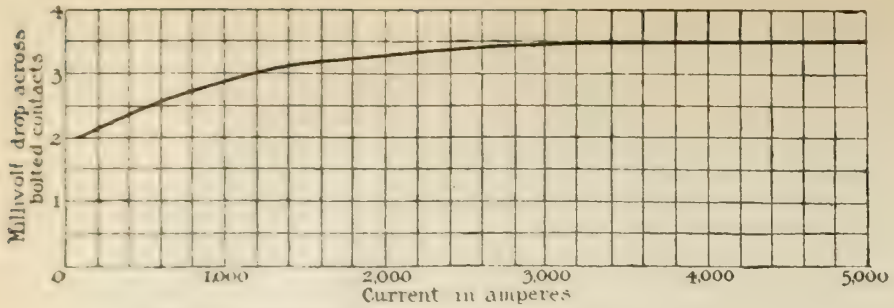

FIG. 12—MILLIVOLT DROP ACROSS BOLTED CONTACTS.

values of time element for open, protected, and enclosed cut-outs, and likewise different time elements for each fuse metal.

Temperature Rise

It is to be presumed that in fixing definite time elements for cut-outs those concerned have regarded them as essential in order to guard against overheating in the apparatus protected by the cut-out.

Considering the thinnest wires, these, according to the Institution wiring rules, would have a working current density not exceeding 5 amperes per square millimetre, and the normal fusing current of the fuse would be three times the working current. This gives a temperature rise per second in the conductors with the normal fusing current flowing of 1.1 degrees C.

A current just below the normal fusing current could flow indefinitely, and whether the conductor will reach a dangerous temperature will depend upon its heat dissipating capacity. It is obvious that to specify a time element for the fuse would not add to the margin of safety. The point is that the factor of safety as regards heating of the conductor is conditioned wholly by the value of the normal fusing current, as a current just below this value can flow continuously.

Turning to larger conductors the current density would be approximately 2 amperes per square millimetre and the normal fusing current double the working current. These figures correspond to a temperature rise of 0.08 degree Centigrade per second. The actual temperature rise of a conductor having a current flowing through it indefinitely in value just below the normal fusing current could only be determined satisfactorily by experiment. The institution wiring rule No. 98 *b* requires that fuses "must be so proportioned to the current to be carried that no conductor protected by them can be raised in temperature above that specified in Rule 44."

It would be very desirable if directions could be issued to guide the user in applying this rule. As it stands, the requirement simply begs the question. It is to be hoped that some information on this subject may be forthcoming before long. At any rate to specify the time element of a cut-out does not serve any useful purpose and it is suggested it should not be done.

Motor Starting-Gear

The most urgent matter in connection with starters requiring standardization is that of rating. Closely connected of course with the standardization of rating is the question of the performance of the device under standard test conditions. The requirement of the American National Electric Code is noteworthy in this connection. This reads as follows (N.E. Code 78 h):—

> "Starting duty resistances for direct-current motors shall be so constructed that when not more than 10 per cent. in excess of the voltage marked on the name-plate is applied to the main-line terminals, and the starting arm is operated at such a rate that the current through the resistance does not fall below the rated full-load current, and this test is continued for not more than three minutes, there shall be no resultant flaming or molten droppings; or if the resistance conductor is fused, the arc or any attendant flame or molten droppings shall be confined within the rheostat."

It would appear that a requirement which allows for the eventual appearance of flames or molten droppings under test conditions is altogether inadequate. A specification of temperature rise and freedom from permanent injury to the device rather should be laid down.

Diversity exists at present among the different manufacturers as regards their horse-power minute ratings of this class of apparatus. This would be obviated in future if a standard rating could be fixed. This is only a matter of definition, and could be settled. immediately if attention were given to the matter by the competent authority.

Copper Strip Connections of Switchboards

It would be a great advantage if the cross-sections of strips to be used for making the connections on switchboards were standardized. Hard-drawn copper is sometimes specified for these. Hard-drawn copper has a specific resistance 2 per cent. higher than annealed high-conductivity copper. Its use, moreover, is wasteful as it has to be purchased in straight, comparatively short lengths. Thus it has to be cut to waste much more than copper purchased in long rolls. Moreover, built-up hard-drawn busbars must contain many more joints which are expensive to make and also the cause of ohmic loss. In view of these facts it would be desirable to standardize on the basis of annealed copper. All strips, except the smallest, should, as far as possible, be of a uniform thickness (say ⅛ inch) but of varying widths. The use of such thin strips permits of large bars being built up with maximum ventilation; moreover, they are very much easier to handle than thicker strips. The sections illustrated in Fig. 12 are suggested as suitable for the proposed standards.

Temperature Rise of Connections

Present-day specifications are very vague on this point. Some engineers specify no appreciable temperature rise, and other requirements such as no excessive rise are common. The measurement of the temperature should be by thermometer. Connections in the immediate neighborhood of instrument shunts should be allowed to run hotter than the normal, as such shunts dissipate their heat to a great extent through the connections. Temperature measurements should therefore not be required to be made within 1 ft. or 1½ ft. of the shunts measured lineally along the conductor. The American Rule No. 722 allows a 30 degree C. rise on cut-outs and current-carrying parts of switches. Large current connections, however, would have to have a higher temperature limit fixed for them than small ones. Reasonable values would be up to 500 amperes not to exceed 20 degrees C. rise; 500 up to 1,500 amperes, 30 degrees C. and 1,500 amperes and above 40 degrees C. A standard of millivolt drop for bolted and riveted connections would be very desirable, and as a contribution to fixing this the curve in Fig. 12 is given showing results obtainable by reasonably good workmanship.

Switchboards

The only British standards (apart from some minor requirements in the Institu-

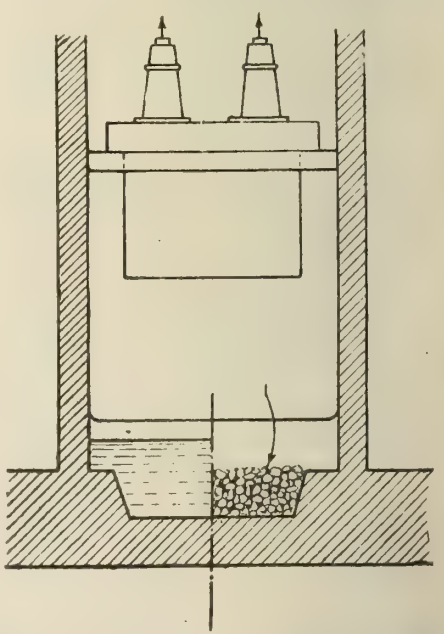

FIG. 13—OIL WELL AT BOTTOM OF OIL SWITCH CUBICLE PARTLY FILLED WITH SAND OR GRAVEL. THE WELL MAY BE COVERED WITH A PERFORATED METAL COVER.

tion wiring rules) as regards switchboard construction which have been as yet established are contained in the official regulations issued by the Home Office and Board of Trade. These latter are, however, concerned primarily with the safety of the workmen and of the public, and while their constructional requirements are excellent in themselves they are not appropriate means for setting up such standards. These should form the subject of special specifications to be issued by the standards committee. Among the requirements to be covered by such specifications may be enumerated the following:—

Clearances, general arrangement of apparatus and connections, prohibition of the use of inflammable material, passage ways, gates, shields, etc.

From the manufacturing point of view it would also be an excellent thing if the dimensions of slabs used in switchboard construction could be standardized. This has already been done by individual manufacturers and, if all could be brought into line, considerable economy would be effected.

As regards high-tension boards, a code of principles should be set up which would guide central station engineers and manufacturers in selecting the type of board most suitable for the particular service required. The matter is of particular importance in view of proposals for linking-up and bulk supplies, which are likely to be considerably extended in the future. Such linking-up is difficult and costly of realization when the stations to be connected are equipped with differing forms of switchgear.

Cellular or Cubicle Type of Switchboards

One of the most beneficial principles of high-tension switchgear construction is the cellular principle originally enunciated by Dr. Ferranti. As of late the desirability of this method of construction has been questioned, the opportunity is now taken of raising a discussion on the subject.

In the author's opinion all high-tensioned boards should be based upon this fundamental idea. Of course the present-day cells or cubicles are very different from the open-fronted pigeon holes originally used. For one thing modern experience has shown that the cells containing the oil switches should be practically gas-tight, or at least only have ventilation or drainage holes from which the emission of conducting fumes or vapors would be harmless. Again, too, the effect of arcs which have been set up as the result of accidents has demonstrated the necessity of very substantial construction of the dividing walls and partitions. There is, undoubtedly, a very considerable amount of practical experience with the use of high-tension switchboards available in the records of the supply authorities in this country. One very beneficial effect of the preparation of the standard specifications suggested would be to render this experience available to the industry generally, with consequent greatly accelerated progress all round.

Reference may be made here to the Commission on High Tension Apparatus set up by the Swiss Elektrotechnischer Verein, and Figs. 13 and 14 are taken from the second report of this commission.

The commission reported that it has been found necessary to leave openings in the oil-switch tanks to prevent their bursting when "internal explosions take place."

Figs. 13 and 14 represent arrangements of cubicles suggested by the Swiss commission to prevent the oil on issuing from such openings from spreading. These are self-explanatory. In Fig. 14 will also be seen a flap-opening to give relief to internal pressures set up within the cubicle. The report also recommends the provision of chimneys for the switch cells

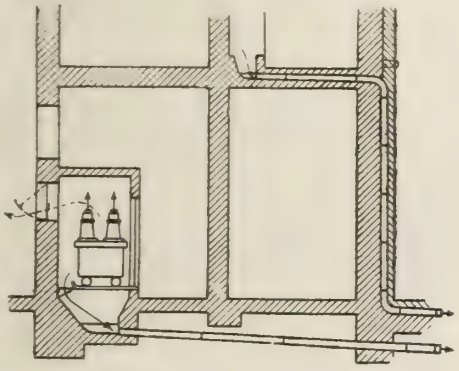

FIG. 14—CUBICLE ARRANGED WITH DRAIN OIL SEPARATOR

to carry off smoke, and that cables should leave each air-tight compartment through porcelain stuffing boxes.

It is very much to be doubted whether the cubicle vent proposal shown in Fig. 13 is advisable, but that on the contrary the cell should be as air-tight as possible. It would almost seem that the authors of these proposals contemplate the bursting or blowing-off of the oil-switch tanks as a normal incident of operation. It is very much better to make the switch tank sufficiently strong to withstand, in conjunction with a sufficient air cushion above the oil, any pressure which may be set up due to operating conditions. Such a construction does not offer any insurmountable difficulty. If a vent to relieve pressure inside the oil switch is provided, then this should communicate through a pipe with the open air or to a place where the expelled fumes are harmless. The provision, however, of a drain pipe as shown in Fig. 14 would seem to be a desirable precaution against accidents. One must not, of course, shut out entirely the possibility of accidents, and from this point of view the enclosure of the oil switch within an outer cell which will strictly localize the ill-effects of any such accident is a great advantage.

Lightning Protective Gear

The horn gap forming as it does a necessary constituent of very many forms of lightning arrester should be standardized as regards its shape and jump-over voltage. This latter depends partly upon the diameter of the rod used in the construction of the horns, and this must therefore be specified. As regards material, both galvanized iron and copper yield good results.

Great diversity exists in present-day practice as regards the size of choking coils used for the protection of machinery against the entrance of dangerous currents. It should be possible, however, to lay down standards (expressed in milli-henries) of inductance which afford reasonable protection in the various cases. If this be done, however, it would be necessary to fix upon a formula which could be generally accepted as sufficiently accurate for the calculation of the inductance of the coils. A mathematically rigid calculation of such coils is a matter of some complexity. Such, however, is not necessary, an accuracy of, say, 5 per cent. plus or minus being ample. A general formula with the necessary curves for use under these conditions should not be very difficult to obtain, and their general use would prevent disputes arising.

Reference may be made to the general formula put forward by Coursey for coils of small radial winding depth and that proposed by Doggett.

The precise shape and arrangement of the coil should for the present be left to the different manufacturers. The minimum clear air space between the turns of the coil should, however, be fixed.

There can be little doubt that the future development of overhead electric transmission is bound up in no small degree with the question of efficient protection against lightning. Of late, two methods for the protection of large systems have come to the front, namely, the static condenser system and the electrolytic. The former has been developed on the Continent and the latter, while it was invented in England, has been brought to its present high efficiency in America. It is probable that most new transmission lines of any considerable magnitude in the near future will be protected by the aluminum electrolytic arrester.

A very considerable amount of development work in connection with the aluminum arrester has been carried out in the private research laboratories of manufacturing firms. While a good deal of the results of this work has been, with commendable broad-mindedness, published in the technical press, naturally much is withheld and regarded as a trade secret. In view of the importance of the matter from the point of view of the future of the British electric supply industry and of the export trade, this is unsatisfactory, as the constants of such a vital piece of apparatus should be common property, just as are, for example, the insulating properties of the commonly used as di-electrics.

PRINCIPLES AND OPERATION OF MODERN ELECTRICAL EQUIPMENT—VI.

By A. M. PERE

LAST month's section took up the action of conductors moving in a magnetic field and explained the manner in which the generator and motor operated by means of elementary armatures consisting of one or two coils. Generators and motors are, however, very seldom built with this small number of coils, the only exceptions being magnetos and small toys.

Armatures for direct current machines were at first built up by winding

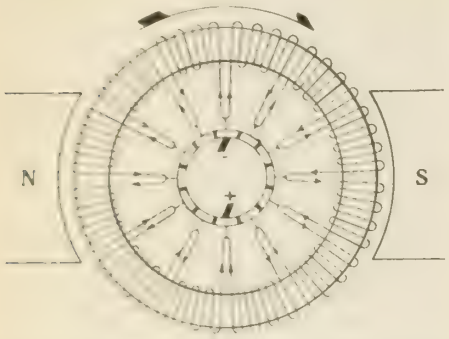

FIG. 1—DIAGRAM OF SINGLE DRUM ARMATURE BETWEEN POLES OF A BIPOLAR FIEL DMAGNET. THE DIRECTION OF CURRENT FLOW FOR THE ROTATION SHOWN IS REPRESENTED BY THE ARROWS AND ONLY THOSE CONDUCTORS ON THE OUTSIDE OF THE RING ARE EFFECTIVE IN CARRYING CURRENT.

coils of wire around a ring of iron or iron wire passing the conductor through the center of the ring for each turn. This construction is open to several very serious objections and is now never used except for a few special purposes. As may be imagined the time taken to wind an armature of this type was no small item and over one-half the wire used was of no value in generating electro motive force.

This will be clearly understood by reference to Fig. 1, which shows the elements of this form of construction. The magnetic flux from the field magnets

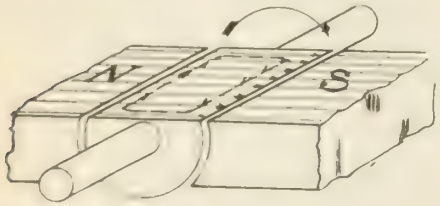

FIG. 2—SHOWING EDDY CURRENTS IN A SOLID IRON CORE, PRODUCED BY THE ACTION OF FIELD MAGNETS.

passes through the air-gaps into the ring of iron and through the ring into the other pole of the field, and the only active parts of the conductors are those on the outside of the ring shaped armature core. The conductors on the inside of the ring do not generate in e.m.f., which is useful but due to the everpresent magnetic leakage across the ring from pole to pole generate an e.m.f.,

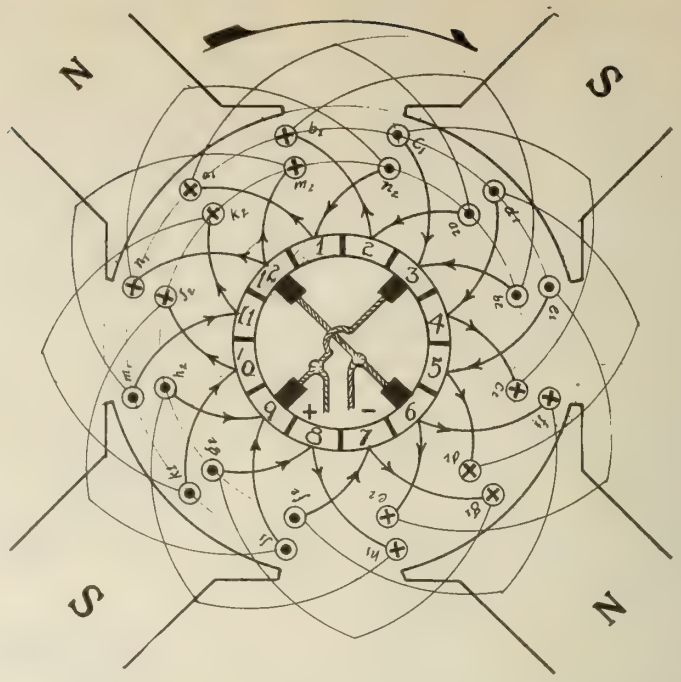

FIG. 3—DIAGRAM OF LAP WINDING FOR A FOUR-POLE FIELD. THE EASIEST WAY TO REMEMBER THE SIMPLE LAP WINDING IS TO REMEMBER THAT THE END OF ONE COIL AND THE BEGINNING OF THE NEXT ARE TOGETHER CONNECTED TO ONE COMMUTATOR BAR

which by tracing out the connections, opposes to a certain extent the e.m.f. generated by the outside conductors. This is understood when it is seen that the current flowing flows back on the inside of the armature.

This disadvantage does not appear in the drum armature and reference to last month's diagrams will show that while the current flows in oposite directions on each side of the loop, the relative directions of the magnetic fields

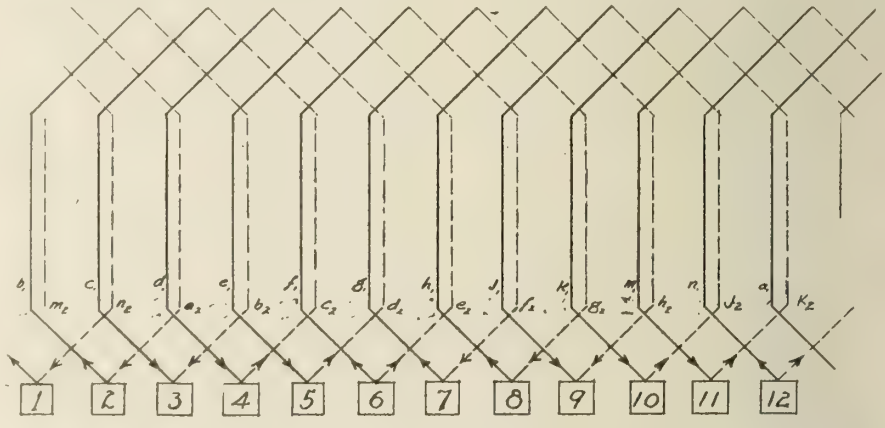

FIG. 4—DIAGRAM OF 4-POLE LAP WINDING 12 COILS. NOTE THAT THE BEGINNING AND END OF ANYONE COIL ARE ONLY ONE BAR APART, THAT IS THE BEGINNING OF A COIL IS CONNECTED TO THE NEXT COMMUTATOR BAR TO THAT ON WHICH THE COIL ENDS.

and the rotation of the armature are such as to strengthen this direction of current flow.

Drum Armatures

It is hardly necessary to say that the dynamo or motor as at present constructed has an armature of which the conductors are wound or placed over an iron core usually provided with teeth between which the conductors lie. These teeth serve several important purposes; they securely anchor the conductors in place, they protect them from injury and they very materially reduce the amount of power required by the field coils in generating the magnetic flux on account of the shorter air gap provided.

Eddy Currents and Laminated Armatures

If an armature be examined it will be seen that it is made up of numerous sheets of thin steel all mounted on the shaft or on a supporting spider of cast iron. The laminations of the core serve a very important purpose. In Fig. 2 is shown a section through a solid iron armature and a moment's reflection will show that revolving this mass of metal in a magnetic field is exactly analagous to spinning a conductor under similar conditions and as shown

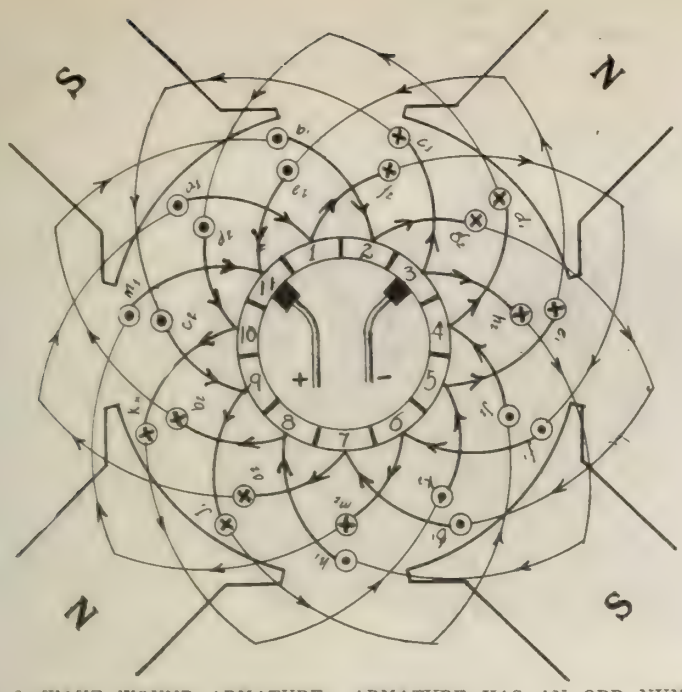

FIG. 5—WAVE WOUND ARMATURE. ARMATURE HAS AN ODD NUMBER OF SLOTS AND END OF ONE COIL IS CONNECTED TO A COMMUTATOR BAR NEARLY 180° AWAY FROM THE BAR TO WHICH THE BEGINNING IS ATTACHED.

in the diagram currents will be set up in the iron. These currents will be o considerable volume, will require energy for their generation, and further, will give rise to considerable heat in the core. Both these factors will reduce the capacity and efficiency of the machine.

By making the core of thin discs of metal and by lightly varnishing one side of the discs each one is electrically insulated from its neighbor and no eddy currents can flow.

Armature Connections

The element of an armature winding or a coil may be defined as that portion of a winding which, being traced from one commutator segment ends at some other segment, the next one encountered in tracing through the winding. A coil or element may consist of one or more turns depending on the voltage for which the machine is adapted and the design of the generator or motor.

That part of the winding in which the electro-motive force is induced or that part lying on the face or in the slots of the core, is called a conductor and for every turn there will be two conductors, each one occupying similar positions under poles of the field magets of opposite polarity.

Methods of Winding

Two modes of grouping the coils, with modifications are in use in the winding of armatures and each one leads to different results. These windings are termed lap or parallel and wave or series windings.

Fig. 1 shows a radial diagram of an armature winding; the circles represent the conductors on the face of the armature and these are shown two deep. The machine being shown with four poles the coils do not go 180° or half way around as in a bipolar type, but only 90° that is, while one side of a coil is under the influence of a north pole the remaining side is under the influence of a south pole in identically the same manner as was illustrated in last month's section.

In Fig. 3 if we start at any one of the bars on the commutator and go along the lead from it which goes to an outer circle we will find that the arrows lead always in the same direction until any one of four bars on the commutator are reached. Starting at bar 1 we go through a coil carrying current away from us to the back of the armature and towards us to the commutator segment (2), or the one next to that from which we started.

When we get to bar 3, we find both leads, which are attached to it, will be carrying current towards it and thus through the brush away from the armature. A little consideration will show that it is at the positions where the brushes are shown that they must be set to collect the currents. The two positive brushes must be joined together and connected to the positive main of the current; and the two negative brushes must similarily be joined to the negative main of the circuit. It now becomes evident that in this lap-wound four-pole armature there will be four paths all in parallel, through all of which current will flow. If the machine were delivering say, 100 amperes, 25 amperes would flow along each of the four paths. This is one of the properties of a lap-winding,—there will be as many paths through the armature as the machine has poles and there will be needed as many sets of brushes around the commutator as the machine has poles.

The type of winding above described is called the lap-winding and its most easily remembered characteristic is that the beginning and end of two adjacent coils are together connected to one bar of the commutator. The armature shown has two conductors in each slot, one above the other, this allows the use of as many coils and commutator segments as there are slots, or if there were twelve slots there would be twelve coils and twelve bars in the commutator. Another arrangement is to only place one conductor in a slot, thus making our twelve slot armature have only six coils and a twelve-bar commutator.

Fig. 4 shows a developed winding diagram of the above armature shown in Fig. 3, and it is considerably easier in some respects to trace out connections from this type of diagram. The coils shown full are those which lie on top of the armature, while those shown dotted are those in the bottom of the slots.

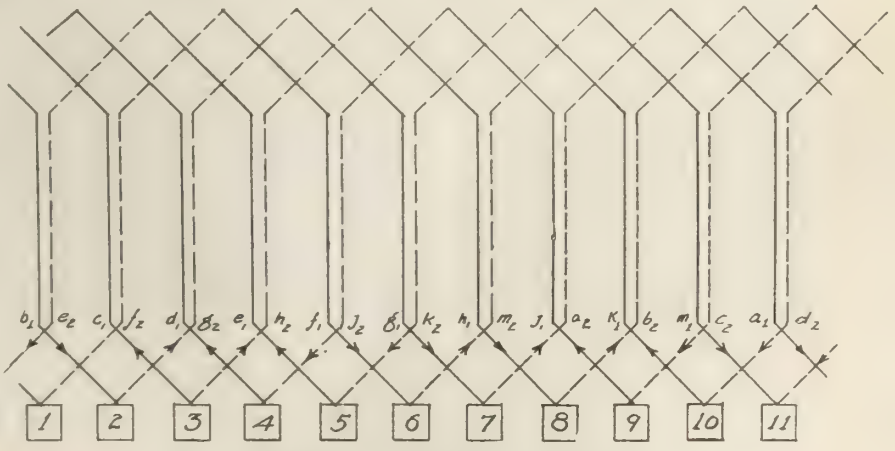

FIG. 6—DIAGRAM OF 4-POLE WAVE WINDING. 11 COILS.

Wave Windings

Fig. 5 shows a wiring diagram of a wave wound armature and it will be noticed in counting that the number of slots, coils and commutator bars is odd; in this case eleven. This is a peculiarity of the wave-wound armature and the number of slots must always be odd, in general it is usually one less than some multiple of the number of poles.

In tracing out the circuits in the armature and in figuring out the direction of current flow it will be found that there are only two points where the currents converge to or away from the commutator. These points are located where the brushes in the diagram are shown and it is one peculiarity of the wave-wound armature that only two brushes are needed no matter what the number of poles, whereas in the lap-wound armature there must be as many sets of brushes as there are poles in the field magnet.

If the winding be traced out from the brushes it will be found that there are only two paths through the armature, one with six coils in it and the other with five. This is just half the number which were present in the lap-wound armature before considered.

It has been remarked that there are six coils in one path and five in the other and this gives rise to the question as to whether the voltages generated in these two paths would be different. This is true to a slight extent, but in commercial armatures the number of coils is so great that the extra coil in one circuit does not have much influence and any coil which at one instant is in the path of the greater number is at the next instant when the adjacent commutator bar is reached in the path containing the fewer number.

This kind of winding is preferred for street car motors on account of the position of the brushes and on account of its adaptability for various speeds.

Both the above windings can be adapted to many other conditions and modifications exist which permit of using two, four or six paths through the armature of a multipolar machine.

Answers to Last Month's Problems

1.—Electricity is generated in a coil of wire by the action of a magnet when the coil and magnet are in movement relative to each other or when the magnetic flux of the magnet is increasing or decreasing.

2.—In a generator the energy used in the turning of the armature gives rise to an electric current through the cutting if the magnetic lines of force by the armature conductors. In the motor the armature is revolved and power given out by the magnetic drag of the field magnets on the armature conductors when they are carrying current.

3.—Read last month's text.

4.—Within limits the voltage generated by a dynamo increases directly as the speed increases, directly as the strength of the magnetic field is increased and increases as the product of the speed and the strength of the magnetic field.

This Month's Problems

1.—Why are the cores of armatures laminated or built up of thin sheets of iron or steel?

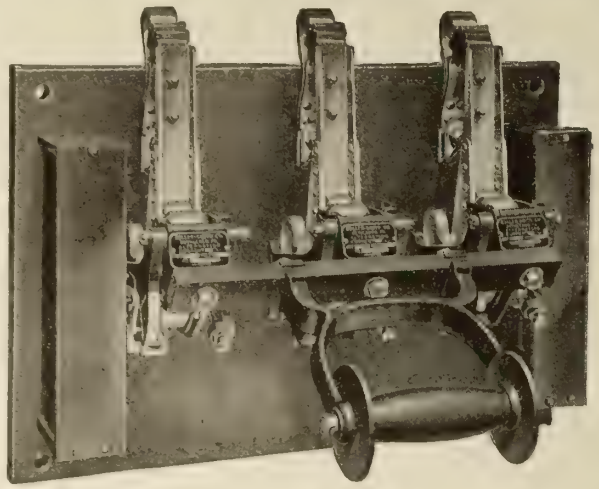
2.—What two general methods of winding direct current armatures are in use?

3.—What are the differences between these two methods?

4.—What differences exist in the brush arrangements used with these two windings?

SELF TIMING CIRCUIT BREAKER

COMPLETE protection of one common class of electrical load, a class well typified by the ordinary motor, requires something more than the usual instantaneous overload release circuit-breaker.



60 AMP. 250 VOLT 3-POLE RIGID ARM ,PLAIN OVERLOAD CIRCUI TBREAKER WITH TWO SELF-TIMING ATTACHMENTS

Take the common occurrence of a motor intermittently loaded. For such loads its safe maximum horse power capacity is evidently greater than with load continuously applied, and, if the installation is to be economical in cost and in operation, that capacity should be utilized. Dash pot delaying means fail to permit this in that they are necessarily restricted to short duration swings.

These requirements are admirably met with in the S.T. (self-timing) circuit breaker manufactured by the Roller Smith Co., New York, whose operation is extremely simple. The breaker itself is of standard construction tending always to trip instantaneously with the load, for which it is adjusted, applied. Interposed in the path of its trip armature is a pivoted hook shaped barrier under two independent controls. One control is thermal. The expansion of a metal rod heated at the same rate the motor is heated by the passage of the same current which drives the motor retracts the barrier and allows the breaker armature to trip if the heating is excessive, no matter how that excess comes about. This thus cares for the starting current and the variable motor loading protection requirements. The other control is electromagnetic, instantaneously retracting the barrier and allowing instantaneous trip if a heavy overload occurs.

Both controls are adjustable, that is to say, both maximum current which may continuously flow and emergency overload trip values may be independently varied by the purther adjustment.

NEW POWER STATION AT GLASGOW

The total power capacity of the new electric power station now under construction at Glasgow, and to be opened next year, is 150,000 kilowatts or 200,000 horse-power. The central station is at Dalmarnock, and electricity will be transmitted at a pressure of 20,000 volts (three-phase alternating 25 periods per second to distributing centres in other districts of the city.

A site measuring 13½ acres has been taken in hand bordering the River Clyde, and an ample supply of condensing water is obtained from that river. The first portion of the works already completed comprise a water intake, a screening house, two water culverts, switch house, turbine engine room, two boiler houses, workshop and store, and a complete coal-handling plant capable of dealing with 100 tons of coal per hour. The cost of this plant is £24,800.

The first instalment of the machinery will consist of three 15,000 kilowatts (20,000 h.p.) turbines, which will be coupled direct to alternating current generators; also three 1,000 kilowatt (1,300 horse-power) turbo sets for driving auxiliary machinery. It is proposed to add plant units of 15,000 kilowatts as the demand increases, while turbines of 30,000 kilowatts can be installed if found to be necessary.

UNIQUE OIL ENGINE-DRIVEN COMPRESSOR

By Frank C. Perkins

The accompanying illustrations show the design of fuel oil engine-driven compressors, developed at Chicago, Ill., to utilize low grade fuel oils and greatly increase the economy and sphere of usefulness of such machines. It is claimed that they have unquestionable reliability, sustaining low operating costs, indestructible flat disc air valves, totally enclosed construction and efficient automatic lubrication and regulation. These compressors have six standard strokes, 8, 10, 12, 14, 18 and 21 inches, with air and power cylinders, and the 8, 10 and 12 inch strokes only are arranged for portable and skid-mounted (semi-portable) use.

This low-grade fuel oil engine operates successfully on crude oil, fuel oil, residuum and stove oil, also on tops, tar oil, solar oil, gas oil, as well as engine distillate, coal oil, alcohol or naptha, benzol or gasoline. It has no valves, gears, carburetors, mixers, oil or air heaters, magnetos, batteries, timers, switches, coils, wires or spark plugs.

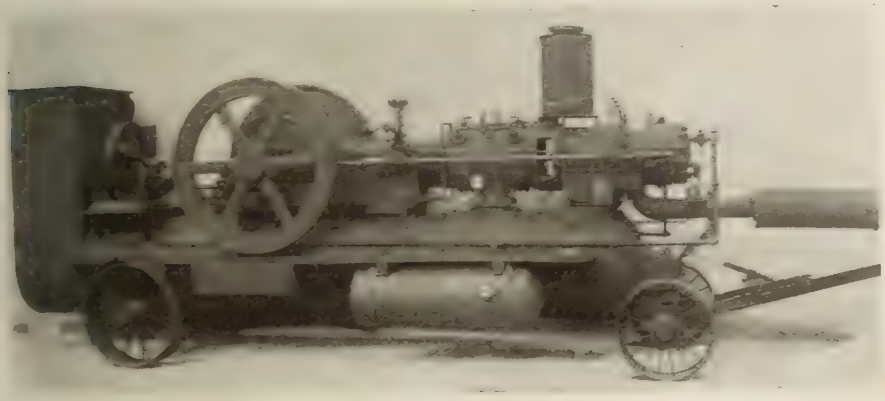
The employment of a single cylinder minimizes working parts and their consequent friction. The crosshead construction is extremely important, providing features of advantage over the trunk piston type that should not be ignored. The crosshead removes from the

piston head the angular thrust of the connecting rod with its tendency to wear the top and bottom of the cylinders more than the sides, with the result that oils of a heavy or asphaltum base will work back and under the piston rings, hardening there and causing excessive cylinder wear.

With the crosshead type all bearings are accessible, and by compressing in the front end of the cylinder instead of in the crank case, better compression is secured, there being no joints to offer opportunity for leakage and the compression space being greatly reduced. Lubricating oil from the crank case cannot possibly enter the combustion chamber and disturb regulation.

The cylinder of these engines is of the valveless, two-cycle low compression type, and the metal used is carefully distributed to withstand the stresses of hard service and at the same time maintain castings of as even thickness as possible. Water jackets are cast integral with the cylinders, but cover only that portion in which the combustion takes place. This construction simplifies the cylinder casting and facilitates the equalization of temperatures at all points.

The trunk type of piston is employed in these engines and provision is made for four self-adjusting eccentric spring rings. These are wider than the admission and exhaust parts, cannot catch or break, and effectually secure the compression which accounts for the efficiency of the engines. It is of interest to note that the method of igniting the fuel charge is positive and extremely simple, with no delicate parts involved and no sensitive adjustments necessary. A thin circular plate is rigidly secured to the piston and after the engine is started fuel injected against this hot plate is



SELF-CONTAINED COMPRESSOR MOUNTED ON TRUCKS FOR PORTABLE USE.

instantly gasified and ignited. By this system air only is compressed in the cylinders, the fuel is injected at the proper time and high sustained operating economies are possible.

STORAGE OF COAL

Some notes on the storage of coal with reference to the prevention of spontaneous combustion were given by Mr. John H. Anderson before the Institute of Marine Engineers, London.

The author said that his remarks were based in particular on experience gained with a heap containing just over 16,000 tons. The heap consisted entirely of small bituminous coal, of several kinds, washed and otherwise, some being of a character supposed to be dangerous for storing. Under these conditions extra care was exercised. Temperature readings were taken at 14 different places nearly every day, and occasionally also at the vent pipes, of which there were 50. Further, to find the hottest part, readings were taken at every foot from top to bottom at certain places. Previous experience indicated that the warmest place was between 6 ft. and 8ft. from the surface; hence 7ft. was established as a standard depth for temperature records. The temperature tubes were ¾in. or 1 in. gas tubing, driven in from the top to the bottom of the coal and long enough to project 2 ft. or 3 ft. above it. In most cases the vent pipes were old scrap tubes about 3 ft. long and 3 in. or 4 in. in diameter, and were driven down to the 7 ft. mark, their ends being flattened, chisel-shape, to facilitate driving.

By taking periodical readings of the temperature of the pile and comparing them with previous readings ample warning was obtained to prevent a fire. If a readying of 90° F., which was adopted as a warning temperature, was obtained at any place four other temperature tubes were driven down north, south, east and west about 10 ft. from the warm tube. The tube which gave the highest reading next day was then made the centre, and other pipes put down in its direction, the idea being to locate the source of heating. When the warmest place was found an additional vent pipe would be put in there, and this generally arrested the rise of temperature. If, however, it did not, a trench was dug a foot deep on each occasion—that is if the readings remained at, say, 100° for three days the trench would be 3 ft. deep. In fact a temperature of 100° was never reached, but on four occasions, when 95° was recorded at a point where the coal

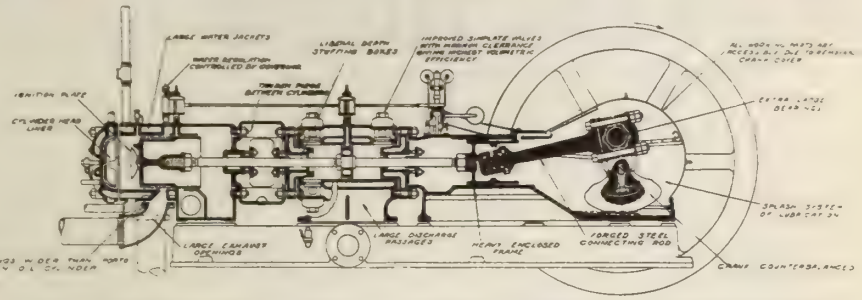


FIG. 2—LONGITUDINAL SECTION SHOWING DETAILS OF CONSTRUCTION.

was deposited to a depth of 16 ft., a trench was dug. Probably, however, this trenching would have been unnecessary had additional vent pipes been inserted. If a fire occurs, although plenty of water should be available to quench it, it is better to dig all round it, and if possible remove the hot coal.

In general the depth of the heap should not exceed 12 ft. to 14 ft. for small graded coals, or 9 ft. to 12 ft. for unwashed mixed coals. As regards slacks, a good deal depends on the composition. The author allowed two heaps of this material 10 ft. deep to rise to 120° before moving them, and they gave considerable trouble; even when they were reduced to 6 ft. there was a tendency for them to increase in temperature. Anything, such as pieces of wood, pit props, rags, waste, shavings, and straw, that ignites at a lower temperature than the fuel should be kept out of the heap. As a rule the greatest danger is up to about three months from the time the coal is taken out of the pit.

IN SOME hydraulic power stations there is, at certain seasons of the year, a surplus of energy available, which is commonly unavoidably run to waste. This has been the case (says Engineering) at the Leten power-station of the Zurich Electrical Power Company. At the same time it has been necessary to maintain for certain purposes a small steam plant. The company accordingly decided to utilize the surplus of power available for maintaining steam in a boiler for this plant. The boiler fitted has 1,800 sq. ft. of heating surface, and, with a maximum consumption of 84 to 86 kw., is able to supply 3,800 lb. of steam per twenty-four hours, which suffices to run the feed-pumps and to keep hot the machines and the piping.

Vancouver, B.C.—The Powell River Co., Ltd., 510 Hastings Street West, contemplates the installation of oil and coal burners costing $500,000 at Ocean Falls Mill.

Greater Things in This World Than Dollars

A company with a large selling force has one man on its staff in the Eastern section of Canada who does a large business. He makes a lot of money for his firm, and he makes a lot of money for himself. He is regarded as a good business man. But he could do twice as much business if he only knew it.

A few weeks ago he sent in an order to the head office in an Ontario city for two carloads of goods. The price he had quoted was $4.50 per ton higher than the price on the company's accredited sheets for that period. The purchaser had been very keen to get a supply. The salesman was quick to realize this, and took occasion to pick off a few more dollars on the deal. The company could have filled the order at the higher price. It would have made some $400 on the shipment and the salesman would have been credited with that much extra.

The company did not stop to write. It wired first to the consumer stating that the order would be filled at a price $4.50 per ton less than quoted, and the next wire went to the salesman. It is not necessary here to state what that wire announced.

A letter followed stating that the company had one price for its goods. When an increase was made every buyer was notified in advance and no favors were shown.

It's too bad that more people can't get that same system worked in under their skins. There are so many people with a dollar bill or a fifty-cent piece jammed up and glued up against their eye that they can't for the life of them get a proper perspective. If they were permitted to gaze out upon the most wonderful sunset that the hand of the Almighty ever painted they could see nothing but the fifty cents or the dollar that might be gathered in from selling reserved seats to witness the production.

The man who is making his first thousand or his first ten thousand will tell you that grabbing money is the greatest occupation in the world. The man who has grabbed and gathered will tell you that he is just as keen to grab a hundred thousand as he was to grab his first ten.

The man who goes into business with the money-grabbing instinct burned into his brain is going to make a miserable failure in the long run. He may get a reputation for being keen—a few deluded individuals may even regard him as shrewd in his dealings. But allow for all that. What else is he getting out of life? Mighty little. And when he gets to the end of his string he will have the poor satisfaction of looking back over a lot of joyless days, penurious nightmares that he thought once were prosperous days—a trip barren of friendships and a career that will bring few mourners to his day of departure.

Real Economy in Burning All the Coal

THERE seems to be no end of advice given officially and otherwise to the Canadian public this year in regard to the necessity of saving coal, both in power plants and in the heating plants for the home. Occasionally there are some suggestions in regard to the proper methods of firing, and the securing of perfect combustion that have some real value, but there is a great deal of wasted and misspent effort in the advice given as a general thing.

Real results are going to be secured in making it certain that the greatest possible amount of heat is secured from the fuel we burn.

A steam engine is a waster at best. It is considered quite satisfactory to use 20 per cent. of the actual steam value delivered to the ordinary engine, and in many cases the figure will be well below that.

Boiler efficiency is another matter that has much to do with the amount of coal burned and the relative amount of heat obtained from it. There are, of course, boiler plants where as high as 80 per cent. of the heat in the coal will be secured, but that is above the average. Perhaps a figure around 60 per cent. would be much nearer.

There should be an effort made to induce power plant users to go ahead and introduce in their premises appliances that will make it certain that they will secure the maximum amount of heat from every ton of coal that goes into their furnaces.

Very little is going to be gained by simply keeping up a harangue that the people should burn less coal. That will probably result in decreased efficiency all round.

The big drive should be to see to it that we burn coal instead of letting a large percentage of the combustible material drift up and out of the smokestack.

Association and Personal

L. W. Adams has tendered his resignation as general superintendent of the Nova Scotia Steel & Coal Co., New Glasgow, N.S., effective Sept. 1. His successor has not yet been appointed.

Edward J. Albert, who for five years has been manager of the mining and power departments of Canadian Allis-Chalmers, Ltd., Toronto, Ont., resigned recently. He now is sales manager of the Thwing Instrument Co., Philadelphia.

William Starke, president of Starke-Seybold Ltd., Montreal, and a well known business man, died last Friday after an illness lasting only ten days. He was born in Montreal and had spent the whole of his life here, being known in many circles. He was 57 years of age and was a son of the late George Kinloch Starke. He received his education at local public and high schools, and his first business appointment was in a hardware establishment.

Captain Edward H. Phillips, E Co., 104th Infantry, an employee of the L. S. Starrett Co., of Athol, Mass., was killed in action in France on the 25th of July. Captain Phillips was an example of the finest type of young American manhood. Last spring he received the Croix de Guerre from the French Government. He was a sergeant when the company was formed and was rapidly promoted to second lieutenant, first lieutenant and captain. The L. S. Starrett Company has one hundred and twenty-four employees in the military or naval service of the United States and Great Britain.

One more official of the Dominion Steel Corporation has been lost in the person of F. W. Gray, who severed his connection with the company and left for New Glasgow. Mr. Gray has been attached to the company since 1904 and during his 13 years' mining experience here had done much to modernize and improve conditions. Graduating in mining from Sheffield university, Mr. Gray obtained training from G. Blake Walker, who is now president of the Institute of Mining Engineers. He is a member of the council of the Canadian Mining Institute, a member of the executive and editor for the Nova Scotia Mining Society and a member of the Institution of Mining Engineers.

Mr. Gray has written extensively on coal and has done much to advertise the coal fields and industries of Nova Scotia. Besides writing a monograph on the coal fields of eastern Canada, he has been a frequent contributor to technical periodicals. It was Mr. Gray who introduced the oxygen breathing apparatus into Nova Scotia. He has taken great interest in first aid work and matters relating to miners' relief societies and the compensation of workmen for injuries.

COMPRESSED AIR FOR CLEANING MOTORS

By Meredith.

In a great many manufacturing plants, especially those working in wood or a similar material, the driving motors have a tendency to become clogged with dust in a short time. Such accumulation of dust is a fire hazard, particularly if the motors are overloaded and liable to have coils burn out; and if a motor is not overloaded it may heat if the air ducts are filled with dust. Moreover, the motor is not able to carry the peaks when called upon, for the reason that the additional heat cannot be dissipated. Motors should be cleaned frequently, but such cleaning with the means ordinarily at hand is a rather difficult procedure since the air ducts are necessarily usually small and difficult to clear with a brush. The windows may be brushed off externally but such cleaning does not reach the real seat of the trouble.

One of the best methods is compressed air under considerable pressure. If the air is not available from some source already in use, it is advantageous to use a small motor driven compressor and a storage tank. The compressor should have a capacity of from 4 to 10 cubic feet of air per minute at a pressure of 100 pounds per square inch, and the tank should hold from 40 to 100 cubic feet. This size will take care of the average plant.

In piping a factory the air line can be in 1 in., ¾ in. and ½ in. pipe. Since the amount of air used in cleaning any one motor is small, a large pipe is not necessary. An outlet with a valve should be placed near each motor, or if they are grouped, several motors can be reached from one outlet with ½-inch or ⅜-inch hole. The smaller size is more easily handled. The nozzles can be made up of bras rod of suitable sizes and shapes, which, however, must have very small openings, as a large nozzle opening would consume too much air. Probably the most useful sizes would be 3/32 inch, 1/16 inch, and 3/64 inch, and these three nozzles will meet most conditions.

The Storage of Bituminous Coal.—The more general storage of coal during the spring and summer months is coming to be recognized as the only practical means of avoiding a coal shortage during the winter. Many corporations and individuals will this year undertake, for the first time, to store large quantities of coal. The storage of bituminous coal presents certain difficulties because of its tendency toward spontaneous combustion with its attendant dangers and losses. The methods to be employed in avoiding combustion have not generally been well understood and those which have seemed successful in some cases have failed in others. The engineering experiment station of the University of Illinois has just completed a study of the problems involved in coal storage and has published the results in a 200-page illustrated book designated as Circular No. 6, "Storage of Bituminous Coal." The study was made under the direction of H. H. Stock, Professor of Mining Engineering. The reasons and advantages of storing coal are given, the kinds and sizes of coal which may be safely stored are described, and the many factors entering into successful storage are discussed. Copies of Circular No. 6 may be had by addressing the Engineering Experiment Station, Urbana, Illinois. The price is forty cents per copy.

Many attempts have been made to weld the particles of tungsten together by working at a very high temperature. No headway has been made in this direction. To be workable, a piece of tungsten must be substantially non-porous—that is, the individual particles must have been previously welded together at a temperature near the melting point of tungsten in an atmosphere of hydrogen or other gas which is either helpful or at least not harmful to the tungsten. Sometimes the swaged tungsten rods split during the swaging operation. Attempts have been made to weld these split portions together by working at a high temperature. The highest temperature available was 1700 -1800 deg. C. It was not found possible to weld the tungsten in this manner. Tungsten can be welded electrically at temperatures near fusion.

Montreal, Que.—The Imperial Tobacco Co. is building an extension to its power house.

The Operators' Point of View

WELDING A LARGE ALLIGATOR SHEAR FRAME

By J. H. Rodgers

ABNORMAL conditions are often mainsprings of unprecedented industrial developments, and these circumstances, coupled with the essential need of maximum conservation of certain materials, are undoubtedly important factors in expansion of many enterprises. The stupendous demand for iron and steel during period of war activities has almost if not entirely eliminated the so-called scrap pile; parts of machinery, and in some instances complete machines that in normal times would be considered as useless, have been given a new lease of life as a result of the great difficulty experienced in obtaining the required article in its initial state, from its original source. Probably no other agency in the wide field of engineering has done so much to reduce the size of the scrap heap as the art of welding, be it the blacksmith, the autogenous or the thermit process. Each method has its own particular sphere of usefulness, careful judgment being frequently necessary to determine which is the best system to adopt to meet the needs of the situation. However, it is reasonably safe to assume that for welds on heavy bulky sections of machinery the best practice to follow would invariably be the last mentioned, that of the thermit process.

An interesting repair by the thermit welding process was recently performed at the plant of the St. Lawrence Welding Co., of Montreal, views of which are shown in the accompanying illustrations. The casting here shown is that of a large steel aligator shear frame, broken through the central rib and the back housing, as a result of the upper jaw being forced sideways through careless work on the part of the operator. Owing to the inability of getting immediate delivery on a new casting it was decided to have the part repaired by welding, so the method here described was adopted and the repair successfully accomplished.

Preparation

In preparing the frame for welding it was located directly beneath a skylight to permit of free egress of the heat and gases, as the ceiling was low and of wood construction. Before proceeding with the placing of the mold, the oxy-acetylene torch was used to cut away

VIEW OF FRAME WITH WELD COMPLETED.

the metal adjoining the crack, leaving a channel about two inches wide through the entire length of the broken portion; this being an essential feature in connection with welds of this character. The space thus provided is then filled with a special yellow wax which acts as the pattern; this wax is generally banked up above the ordinary level of the casting to provide additional metal at the broken section. This practice is not absolutely necessary, but where no interference will result the surplus metal is preferable as an added assurance of safety. During the preheating operation this wax is melted, leaving the hollow chamber for the fluid metal.

With the wax in position the sheet steel casing was placed over the broken portion in such a manner as would permit of placing the pouring gate and riser patterns in their desired location. This also applied to the heating gates, one of which was placed on either side and close to the bottom of the mold. Provision was made at the top of the mold in the form of a large basin, to carry the slag.

When ready for preheating the crucible was supported above the mold by means of a girder placed across the skylight opening. The preheating apparatus, shown in the background of Fig. 2, is a Thermit gasoline compressed air unit for generating the gas required for the preheating of the broken section, preparatory to the actual welding operation. This particular type is provided with a device for removing the moisture from the air before the same mixes with the oil; it is also equipped with two independent hose connections for operating two burners.

Preheating

The preheating on this job required considerable time, due to the heavy section of the broken portion and also to the fact that the pressure was insufficient to maintain a capacity flame at the heating gate. When the part was near the desired temperature the thermit —350 lbs. of which was required—was placed in the crucible, the latter being additionally supported on rails laid across the top of the molding frame. The burners were then removed and the heating gates plugged and banked with floor sand.

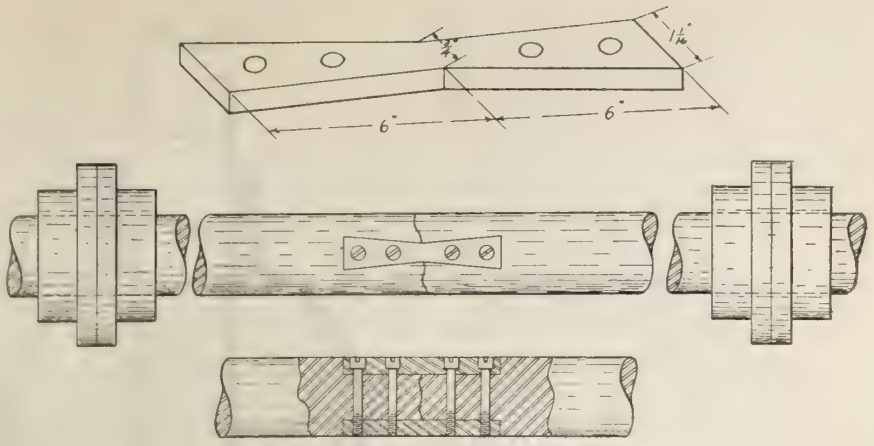
With everything in readiness the welder in charge places about one-half teaspoonful of the ignition powder on the top of the thermit in the crucible and then places the cone-shaped cover in position. A red hot rod is then inserted through the top of the cover and into the ignition powder, which is immediately ignited, and the chemical reaction is so rapid that within ten seconds the 350 lbs. of metal is converted into a molten mass at a temperature of over 5,000 degs. Fahr. In this particular instance, owing to the low heat of the casting before pouring, the metal was tapped less than ten seconds after ignition, so that the final stages of the

reaction process would take place in the mold, thus assisting the fusing of the surrounding metal.

Detail Reference

Fig. 1 shows the work during the preheating operation, with the gas hose leading to either heating gate, and the crucible suspended in position. Fig. 2 shows the pouring process twelve seconds after the initial ignition. Fig. 3 shows a close up view of the finished weld with the pouring gate, riser, and one of the heating gates, before removal by the oxy-acetylene torch. The method of reinforcing the weld is clearly illustrated. The total weight of the casting was over 7 tons, and the completed weld was entirely satisfactory in every particular.

One of the great advantages of the thermit method of welding is the uniformity of expansion and contraction, a factor that is of vital importance in the greater number of machinery repairs, particularly where these are bulky and irregular in shape. The gradual rise in temperature during the preheating operation and the almost instantaneous distribution of the molten metal to all parts of the section to be welded virtually eliminates the possibility of internal stresses being set up in the material.



DETAIL OF REPAIRS TO LINE SHAFT.

REPAIRING A LINE SHAFT

By J. H. Houldsworth.

A main line shaft broke between two couplings as shown in sketch, and was repaired in the following manner:

The shaft was 6 inches diameter, and the repair had to be executed as quickly as possible. The first thing done was to take a bar of steel and make two keys ¾ inch wide at the centre and 1 1/16 inch at the ends by ⅞ inch thick and 12 inches in full length. The keyway was drilled out with the shaft in place with a portable electric drill, then chipped out with an air gun and the keys made a good fit, two being placed diametrically opposite each other.

Four ½-inch holes were drilled and tapped in the shaft and fillister head screws were made with a long head to allow them to be screwed home tight.

Although a new piece of shaft was secured, we had no occasion to use it, as since the repair was made the whole thing was welded with a portable outfit which made a very satisfactory job and at a much less cost.

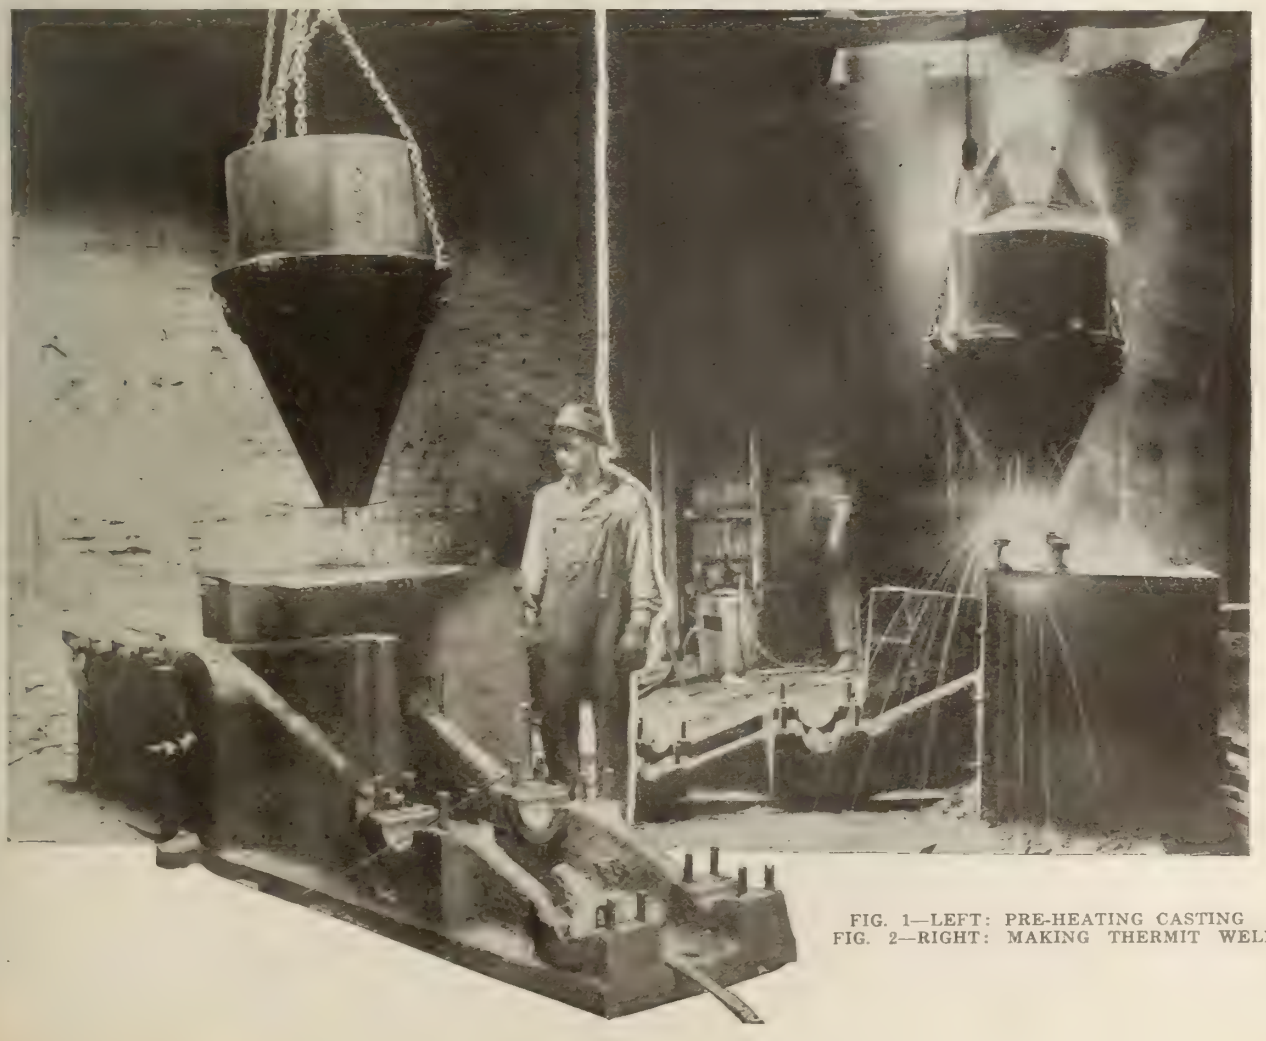


FIG. 1—LEFT: PRE-HEATING CASTING
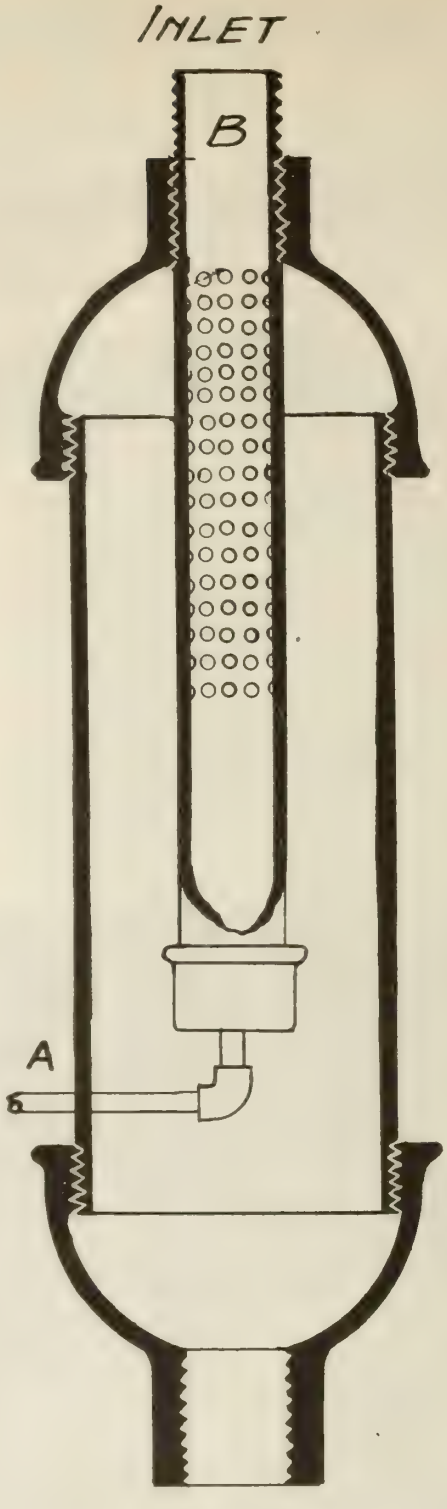
FIG. 2—RIGHT: MAKING THERMIT WELD.

OIL AND WATER SEPARATOR

By J. E. Noble

FIG. 1 shows an article easily made from pipe and fittings. When used as an oil and water separator from a steam engine exhaust, the pipe A is run to an oil trap where the oil can be collected and saved for refiltering, or if it is not desired to save the oil, the drip can be run from the oil trap to the sewer, or direct from the separator to the sewer. A small gate valve should be placed upon the pipe A. The small holes shown should, in the aggregate, be equal in area, or greater, than the area of pipe B. If the device is used on a live steam pipe as a water separator only, the pipe A can be run to the hot well or feed water heater; in either case it would be good engineering to connect A to a small steam trap. The device may be used as an exhaust silencer on a gas engine, in which case the small holes can be extended down to the cap or a shorter pipe used, and the small pipe A dispensed with.



OIL SEPARATOR.

THE WOOD WORKING ENGINEER

By D. A. Hampson

GASPER Chase was a self styled "wood working engineer" and really there seems to be no good reason for objecting to such a term. Chase had a shop that made wood specialties from wooden nutmegs to picture frames. He himself knew the business from A to Z and had the respect of all in his own line who knew him. They phoned to us one day to know if we had any babbitt, good for spindle bearings. Said they had been buying of the F—— Co., who did their repair work, but the babbitt didn't give satisfaction.

Well, we supplied them with Mongolia and genuine babbitt and No. 4 metal during the succeeding year but they complained a good deal about all three. To our queries they replied that they most certainly did not overheat the babbitt, they used a good grade of mineral oil, they did not set the boxes up too tight but still they had trouble with the bearings and journals roughing up. They lost much time re-pouring and with hot bearings.

Frank, our outside man, was going past their shop one day and we asked him to stop and see if he could find any reason why they were having so much trouble. It happened that he was just in time. The men who did their babbitting had finished pouring the boxes of a planer and had scraped them to a fair fit. When Frank entered the room, he was putting the final touches on with a piece of emery cloth wound around a [illegible] smoothing the babbitt with emery. Frank asked if he didn't know that the particles of emery would stick in the babbitt and cut the shaft and would work lose and roll around tearing up the surface of the box. No, they hadn't heard of that and thought emery cloth was the proper thing to use on all metal.

Before Frank left he had thoroughly instructed the force in the babbitt scraping process which requires no finishing. Mr. Chase was called in to O. K. the change. He had seen the man emerying the boxes but did not know that it was wrong, "I'm a wood working engineer you know and so far as I knew that was the right way to do—but a man can't know everything." They got results from any grade of new babbitt after that.

READERS' QUERY

Question.—In a single truck trolley car having two motors one motor makes 100 revs. per min. more than the other. In what manner is the speed of the motor reduced to that of the other?

Answer.—The speed at which the motors of a trolley car run is a function of the size of the car wheels. As the wheels may vary slightly in size from one pair to another the speeds of the motors are not necessarily the same. This variation in speed is taken care of in the design of the motors, and a slight variation in speed caused by different wheel diameters is not objectionable, a slightly greater amount of power being given by one of the motors. The motors used are series wound for this reason as a slight variation in speed at the usual operating speed does not involve much variation in current consumption.

Question.—What horsepower is required to run an air compressor at 250 revs. per min. delivering air at 10 lb. per sq. in. and having a single cylinder 18 by 14 in.?

Answer.—The horsepower required depends on the number of cub. ft. free air delivered per minute and the pressure at which it is delivered. In this case the number of cub. ft. free air per min. will be about 1,000. To compress one cub. ft. free air to 10 lbs. pressure requires about .0361 h.p. and to compress 1,000 cub. ft. will require about 36 h.p. This does not take into consideration the friction losses etc. of the compressor and about 40 h.p. would be required all told.

IN a power plant the attendants are making clever use of the periscope idea. In order to read the temperature of the oil in transformers it has been necessary in the past to use a step-ladder to reach the thermometer mounted on the top of each unit. By using a simple periscope on each transformer it is now possible for the attendants to read the thermometer scale, which is illuminated by a lamp suspended near it, from the floor. —D. S.

* * *

LEAKAGE past the valves and piston will materially reduce the intake capacity of an air compressor. If the area of the intake valves is too small the cylinder will not be filled with air at atmospheric pressure, and, if the area of the discharge valves is too small all the air compressed will not be discharged. Poppet valves depend upon a difference in pressure on the two sides of 2 to 5 oz. for their action and may reduce volumetric efficiency by as much as 2 to 4 per cent. Mechanically operated valves of the Corliss type are very satisfactory but must be maintained in correct adjustment.

Hull, Que.—The Hull Electric Co., proposes to build an addition to its plant at a cost of $30,000.

THE TROUBLES OF AN EMBRYO ENGINEER

By Batiste Lefore

My name is Batiste Lefore, I am ze french mans, I have been having ze troubles wis ze steam plant las week.

I was ze sweep de floor man in ze factory but every time de engineer clean out dose boilers he ask for Batistee to help hem. Well dat engineer he go to fight de hun and me Batistee being old fellow, I stay home. De boss say Batistee, how you like to be engineer and mak tree dollar a day. I say, sure for dat is fine job, all dere is to do is shovel in coal to keep dat steam up, oil up de engine and shafting, lace de belts, sharpen de knives, wash de windows, and sit down when nobody can find anyting for me to do. Sure, I make a grab for such a snap and de next morning I am on de job at 5 a.m. I fill up the fire hole wid coal and at 7 a.m. de whistle I blow for start work, de big valve called safety she be blowing at de same time.

After awhile de Boss come in and say, damn it Batistee why you let dat safety valve below. I say I tink she do dat for safety. He look at de glass and say where is de water, I tell him it is in de boiler I nevaire take eet out. He yelled pull out your fire or she will blow up, den he runs away and I runs after him. Well pretty soon de fire goes out and we get the boiler men to fix her up again and de boss show me how to put in de water and say do not let the safety valve plow so much. I am getting on fine and one day when I am painting de walls a feller comes in and says are you de engineer, I tell him I am him. He say I am inspector Dan Sharpise. Where is your certificate? I say, what is dat. He say a licence. I tell him I am not a dog and do not need a tag. He say you go to dose examiners and get a licence or I put you in ze coop. I say sacre, I not go in any hen coop. I go to see dese examiner fellow. He say Batiste vos you an engineer? I say sure. He say describe de engine you run. I tell him dere is a pipe to take de steam in and anoder one to take it out and a rod runs out and in and turns de wheels around. McGee he say. Ha name de valve on de engine. I tell him de only valve on de engine is de one de Boss called de trottle. He say, hang it man, I mean de valve in de steam chest. I tink dat McGee he been having some 2½ per cent. to talk about chests on de engine.

He ask me do I know how much lead and lap de valve. him got. I start to laugh for I tink he joke me. I say sure McGee. I tie de string to dot valve and lead him around de mill and let him lap up some milk like a cat. Den McGee be get red in de face and say damn some times more. Den McGee ask me if it is good plan to put valve between boiler and safety valve, and I say, sure, because if I had valve dere I could shut him when de steam gets high pressure. He say damn again. He say to me I expect if de water got out of de glass and a big fire on you would run away. I say, sure, again, dat is just what I did do a little while ago. He say, see here Batistee, you no damn good as an engineer, go away and learn sometings and come back next year. Anyhow I am going to write to dose correspondence schools on Yongs street, Toronto, and pretty soon I will be a mail order engineer wid a salary of $3 a day, and noding for Sunday or overtime work. By gar, dere is a lot to learn in dat engineering.

THE PRODUCTION OF LIQUID AMMONIA

By Mark Meredith

Until the beginning of the war Holland was dependent for its supply of liquid ammonia upon England, Germany and more particularly Belgium. At the commencement of 1915 no liquid ammonia was to be had in Holland, as not only the ammonia itself, but also the steel cylinders for containing it, had been commandeered in the belligerent countries, or declared contrabrand of war. This caused much trouble to the industries making use of low temperatures. Calculation showed that the total annual consumption of Holland would amount to something like 27,000 kilogrammes.

At the Arnheim gasworks all the ammoniacal liquor produced was generally converted into pure concentrated ammonia solution: but during the war the high prices of sulphate, and the national need for artificial fertilisers, led to part of the ammonia being sent out as sulphate. The ammonia as driven off is saturated with water; but it is important now to obtain it as dry as possible, to ensure the safe working of refrigerating machines. The restrictions in this connection are therefore of increasing severity. Whereas some twenty years ago 0.9 to 1 per cent of water was permitted in liquified ammonia, the maximum now allowed has been lowered to 0.4 to 0.5 per cent. The drying properties of chloride of lime cannot be made use of, as it combines with ammonia. Caustic soda too is valuable in these days, so there remains only as an available drying agent burnt lime. This, however, has insufficient drying effect, except under pressure. With the pressure at normal, the lime generally left 0.9 to 1 per cent of water in the gas. The most effective means of producing totally anhydrous ammonia—with 0.05 per cent of water—is by evaporating the liquified ammonia, and subsequent reliquifying of this volatilised first product.

At the Arnheim works efforts have been made to eliminate the greater part of the water by cooling. To the current of wet ammonia gas, there is added liquified ammonia at a regular temperature. By the evaporation of the liquified gas the temperature falls as low as 15 deg. C. Thus the water is condensed, after which the gas is led through the drying apparatus. The condensed water is of course saturated with ammonia and leaves the compression plant through a syphon. The amount of liquid ammonia, about 7 per cent of the total bulk produced, is naturally not lost, as it is liquified again. It is taken from cylinders and not from the general storage holder, to permit of control of the quantity used. After this treatment the gas passes through two towers filled with lumps of burnt lime; the inlet being at the upper side, the outlet at the under side. Provision is made for subsequent treatment of the gas with caustic soda lumps in a separate tower.

After these processes the gas passes to a large storage holder, from which it goes to compressing plant very similar to that in use for the manufacture of ice, except that there is no brass and the compression cylinder stands in circulating cooling water. Mineral oil is used for lubrication, an oil-separator being placed after the compressor for removing the surplus oil. In spite of this cooling, the ammonia gas when compressed at from 7 to 10 atmospheres becomes warm. It is condensed in a large cooling coil, and then collected in a storage receiver of about 70 gallons capacity, thereafter being emptied from this into the steel bottles.

On the pressure side of the compressor, and above the cooling coil, there is a blow-off tap. The permanent gases, and more especially the air, which accompany the ammoniacal gas from the stills are blown off during the working, and conducted through water for the retention of the ammonia. From the storage receiver the ammonia is charged into steel bottles, after these have all been emptied by a small pump operated by the The chemical and physical properties of gaseous and liquified ammonia are well known; but there is one peculiarity which may be referred to—the high expansion co-efficient of the liquid. At ordinary temperatures this expansion is less marked, but at slightly raised temperatures the increase becomes very marked gramms.

At 10.0° C.	pressure is	88.2 lb.	per sq.	in.
" 50.0° C.	"	" 294.0 lb.	"	
" 65.7° C.	"	" 455.7 lb.	"	
" 67.7° C.	"	" 860.0 lb.	"	

Thus, for a rise of temperature of only 2 degrees C., the pressure is almost doubled. The filling of the bottles therefore needs special care, for when the expansion is not taken into account an explosion of the bottle is to be feared. The delivery of high ammonia during the first year amounted to 40,000 kilogrammes.

"Good Work, Alexander! Let Loose Your Lusty Crow"

Your work was well done. You remembered that tube cleaning is divided into TWO parts:

1st—removing the scale.
2nd—doing it without injuring an otherwise sound tube.

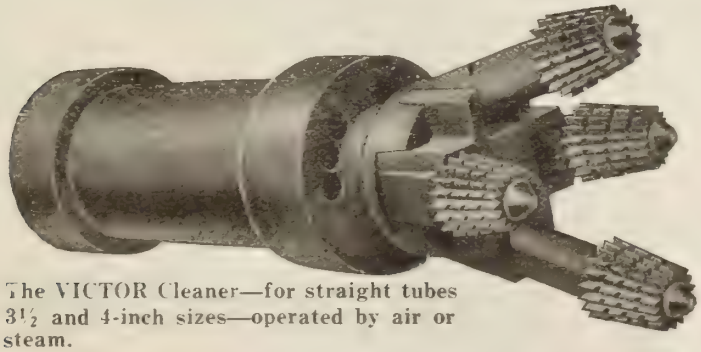
Think well of these *two* aspects of tube cleaning.

Remember, it isn't just a question of getting scale from the tubes—dynamite might do that.

Call in Alexander, the VICTOR Tube Cleaner. He handles tube cleaning from both angles.

He is a success from beak to spurs!

Write for Catalog 14 with facts on the full line of Liberty Tube Cleaners



The VICTOR Cleaner—for straight tubes 3½ and 4-inch sizes—operated by air or steam.

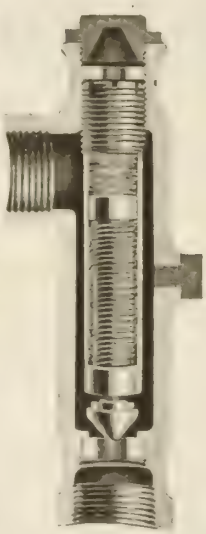
Liberty Manufacturing Company

443 Diamond Street, Pittsburgh, Pennsylvania

Steam Trap SARCO

is Automatically Operated by its Own Hydraulic Pressure.

The strongest and most convincing argument we can offer is a free trial of this wonderful, powerful and efficient steam trap. Put one to work at once and by actual experience and test learn its many advantages.



Steam Trap Sarco will fit any steam line as an elbow, or angle connection requiring no building up nor pit digging.

Its operation is simplicity itself. Only one moving part. The Sarco after once adjusted will automatically keep any steam line free of condensation without waste of steam.

Small in size. Easily installed. Automatic in operation. Equal in capacity to float or bucket trap. For high and low pressure. Unusually small in cost.

Try one and check up these points of merit.

TRADE GOSSIP

Montreal, Que.—Lamontagne Ltd., are building a factory and power house to cost $55,000.

Amherst, N.S.—The International Engineering Works will build an extension to its factory.

Sudbury, Ont.—A new boiler house will be built at St. Joseph's Hospital. H. D. Evans has the contract.

Tillsonburg, Ont.—The Tillsonburg waterworks tower has been destroyed by fire. Loss estimated at $50,000.

Toronto, Ont.—The J. Whitefield Co. will build an addition to the plant at 33 Sherbourne street, to cost $6,000.

Toronto, Ont.—The Lancashire Dynamo & Motor Co. will build an addition to its machine shop to cost $3,000.

Guelph, Ont.—The installation of a pumping machine, $16,000, is contemplated by the City Water Commissioners. Engineer, F. McArthur.

Prince Rupert, B.C.—The Prince Rupert Hydro-Electric Co. contemplate the erection of a waterpower plant. City engineer, P. Lorenzen.

Levis, Que.—Plans are being prepared for a $100,000 filtration plant for the City Council. Engineer, Edouard Hamel, St. Peter street, Quebec.

Lauzon, Que.—The construction of waterworks costing $10,000 for the Town Council is under contemplation. Engineer, E. Hamel, 21 St. Peter street, Quebec.

Woodville, Ont.—A by-law will be voted on by the ratepayers on August 19 to raise $1,500 to provide for the cost of completing plant for the distribution of hydro-electric power.

Rainy River, Ont.—A by-law was submitted to the ratepayers on August 12 to authorize an expenditure of $31,000 to purchase the plant and equipment of the Rainy River Electric Light & Power Co.

Calgary, Alta.—The Dominion government is about to undertake the work of testing the gases of all the Alberta fields with a view to ascertaining the gasoline contents in each. The work will commence in the Calgary field under the supervision of D. R. Dawling, of the Canada Geological branch.

Less Anthracite for the Railways.—The supply of anthracite coal for Canadian householders next winter will be helped out by an order of the Canadian Railway War Board, directing the railways to use no anthracite in stations or elsewhere, except in the Baker heaters used in passenger cars when heat from the engine is unavailable. These require anthracite. In addition to the annual 10,000,000 tons of bituminous coal required for locomotives and in railway shops, the roads had estimated their requirements of anthracite this year at 96,000 tons. Of this amount the new orders of the Canadian Railway Board will save over 60 per cent.

To Speed Up Cape Breton Mining.—Hon. A. K. Maclean expects to leave for Sydney, C.B., at the end of the week in an endeavor to stimulate production of coal from the Cape Breton fields. Advices received here are that production in this area is much below capacity and must be speeded up if a coal crisis is to be avoided next winter. At the present time the outlook is admittedly serious. A number of manufacturing firms are reported to be without prospect of securing necessary supplies and may have to close down. Complaint is made that owing to the high wages the miners now receive many of them are not working the full week, and production is suffering in consequence.

Kipawa Fibre Co.'s New Mill.—According to advices to hand, the preliminary work of erecting the large sulphite plant of the Kipawa Fibre Co. at the foot of Lake Temiskaming is under way. This plant is a subsidiary concern of the Riordon Pulp and Paper Co. Three hundred and fifty men are engaged in construction work by the George A. Fuller Co., which has the contract for the building of the new mill. The site for the mill, about 80 acres in all, has been cleared, and the contract has been let for the clearing of the townsite. The work of putting in the footings for the digesters and the shipping room is under way, the rock is being blasted away from the site of the power plant, and a coffer dam is to be erected soon. Sulphite pulp and all kinds of wood fibre will be turned out at the plant when completed, and the capacity will be large.

Crude Rubber Supply Curtailed.—Radical curtailment of the amount of crude rubber available for manufacture into pneumatic automobile tires may be expected in the near future. Conditions throughout the rubber business are such that the war necessities of the United States government are also certain to call for a sharp cut in the use of pleasure cars within 60 days. These two facts form the outstanding results of the meeting of all branches of the rubber industry on Wednesday at the Waldorf-Astoria, when representatives of the War Industries Board explained the situation to representatives of the rubber trade. The government expects the manufacturers to cut in two their output of pneumatic tires for pleasure automobiles during August and September. The programme also calls for restriction in production of many other semi-essential rubber products for the next two months.

Scarcity of Coal in U.S.—Coal miners and operators are called upon in a proclamation by President Wilson to give their maximum effort to the production of coal to the end that threatened shortage next winter may be avoided. The President asks the miner particularly to work full time, and urges those who are essential to the industry to accept deferred classification in the draft. "The existing scarcity of coal," said the proclamation, "is creating a grave danger—in fact the most serious which confronts us, and calls for prompt and vigorous action on the part of both operators and miners. Without an adequate supply our war programme will be retarded; the effectiveness of our fight-

ing forces in France will be lessened; the lives of our soldiers will be unnecessarily endangered, and their hardships increased and there will be much suffering in many homes throughout the country during the coming winter."

CATALOGUES

Silent Chain Drive.—Link-Belt Co., Chicago. Book No. 312. Describes the application of a silent chain drive for operating machine tools of all types. There is a brief description of the construction of the chain, but by far the larger portion of the 40 pages comprising the book are given over to views of the chains in actual use.

Oil Engines.—Buckeye Machine Co., Lima, Ohio. Catalog. Illustrates a semi-Deisel engine using low grade fuel oil. Among the features of the engine upon which emphasis is laid are ready accessibility of all working parts and the elimination of overhanging flywheels. These points are brought out by a series of illustrations which supplement the description of the engine. Mention is made of the special expanding type friction clutch which is provided.

Welding and Cutting Apparatus.—An attractive loose-leaf catalogue has been issued by the Bastian-Blessing Co., Chicago, Ill., describing the "Rego" line of oxy-acetylene welding and cutting apparatus, lead burning equipment, regulators, etc. The "Rego" outfits are illustrated and described, followed by full details covering the "Rego" cutting and welding torches. The "Rego" diaphragm regulator is also described fully, together with matter relating to other regulators for cutting and welding.

Twist Drills and Cutters.—Butterfield & Co., Inc., Rock Island, Que., has issued to the trade a twist drill, gear and milling cutter catalogue "A" which covers a full line of the product and also contains much useful information for the use of customers. The catalogue is arranged in four sections, cutters, high power cutters, drills, arbors and general information. The first section contains some useful data on cutting gears and tables of cutter sizes, and prices, etc. The drill section contains instructions for grinding twist drills and price lists covering the full line. The general information section contains B & S tapers, tables of cutting speeds and decimal equivalents, etc. This is a handy catalogue to have in the shop for reference.

NON-CORROSIVE CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS
An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.
E. H. KELLOGG & CO.,
New York, U.S.A.

MONCRIEFF'S "UNIFIC" WATER GAUGE GLASSES
Stand in a Class by Themselves for Quality, Efficiency and Economy

Success and Your Associates

ALWAYS associate with men who are earning more money than you are. Such is the advice given by a man whose name is known the world over for his own success and the business which he created. It is good advice of a certainty, but we are not urging that it is the best advice. At the same time it is wise to associate with better or bigger men than you are yourself, because you are likely to be lifted up to their levels.

Most of us would probably like to be the intimates of J. P. Morgan, or of John D., or of Charlie Schwab, or Canny Andrew. If we had a speaking acquaintance with John Wanamaker, or Lord Beaverbrook, or Lord Shaughnessy, and with other distinguished and successful men, we would take comfort from the fact.

And most of us would feel rather small and uncomfortable if we were placed beside President Woodrow Wilson at a dinner table, or beside Sir Robert Borden, Sir Herbert Holt or Sir Wm. Mackenzie. And the reason would probably be that we know so little of the knowledge that really counts. If these successful business men engaged us in conversation we would probably find ourselves knowing very little about the things that matter.

This will illustrate the point:

Here's a true story. A Toronto manufacturer found himself on a train going to Albany in company with a number of distinguished Americans about to attend the inaugural ceremonies of a State Governor. A washout led to a delay, and the Canadian was thrown into close association with senators and congressmen and prominent lawyers. They bantered the little Canadian about Canada. He had the pluck of a bigger man. He had been a constant reader of THE FINANCIAL POST, and had absorbed many facts about Canada. He surprised his American travelling companions with his positive, well-informed and wide knowledge of Canada. When the company reached Albany, the Canadian was persuaded to attend the ceremonies and was introduced as the man who knew all about Canada. The Governor was interested in Canada, and said so, and the little Canadian found himself telling the story of Canada very ardently to a very attentive listener, much to the amusement of his friends who introduced him.

This man made a hit on that journey, and many friends. One of the company gave him a stock market tip worth a fortune.

The point of this story is: You, as a Canadian, can make yourself informed very fully and intelligently if you become a regular reader of THE FINANCIAL POST. You can make yourself a worthy companion and intimate of presidents and magnates. The world likes to listen to men who know something well, and who can talk interestingly and informingly on the subject of their study.

You can become worth listening to if you know your Canada well. And you can get the kind and amount of knowledge concerning Canada which will make you interesting to others if you will read THE FINANCIAL POST regularly each week.

IF you read THE FINANCIAL POST REGULARLY you will find yourself keeping company with the highest paid staff of editors engaged on any publication in Canada—trained men who know how to make others know what they know and learn.

You will find yourself living in a most interesting world—the great, throbbing world of business. You will have your thoughts tremendously stimulated and helpfully directed. You will find yourself becoming a fit table companion for big men — this because you will have knowledge of a quality that will keep you from shame.

What is it that keeps you and THE POST separated? It cannot be its subscription price of $3. Probably it is because you are not very well acquainted with this paper.

We are going to put it to you this way: If you have the desire to be worthy of association with big men, then prepare yourself for such association by reading THE POST, and to make acquaintance easy, we provide the coupon below. It offers you THE POST for four months for a dollar bill.

The MacLean Publishing Company, Limited,

143-153 University Ave., Toronto.

Send me us THE FINANCIAL POST for four months for One Dollar. Money enclosed to be remitted

(Signed)

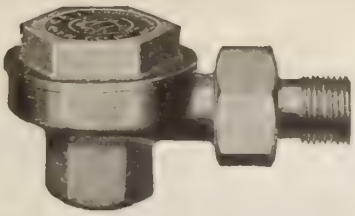
You Can Help Him Save Fuel

Every employer in Canada realizes that he must use with greater efficiency what coal he can get, or possibly reduce his output.

Proper use of the coal in the boiler room is one way of saving it; here you can help directly. Keeping all valves tightly packed is another helpful way. But the biggest waster of coal is caused by water and air in radiators. It is this waste that is stopped by the Dunham Radiator Trap. Tell your employer about it.



The Dunham Radiator Trap makes every radiator give more heat at less cost. This statement we can prove by facts from installations in which remarkable fuel savings have been made. Dunham Radiator Traps can be installed without necessitating expensive alterations. Ask us to tell you how.

The DUNHAM HEATING SERVICE

You can get five to ten inches of vacuum **without use of jet water**—and superior and easily maintained circulation on low pressure —and with no broken vacuum due to leaky traps.

Write to-day for all the facts.

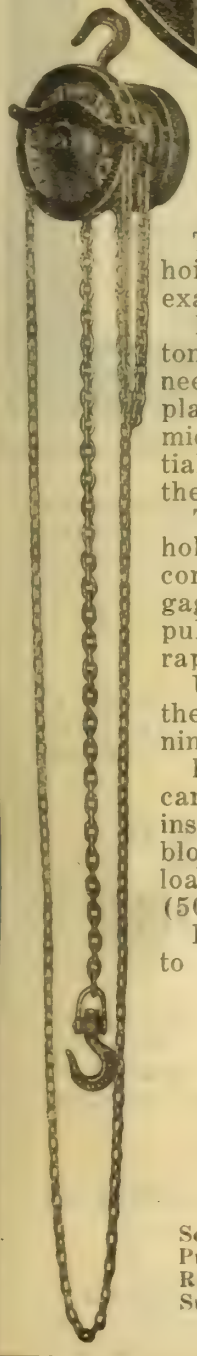
TRADE YALE MARK

Yale Blocks Setting Heavy Machinery



YALE HOISTS

For CRITICAL Hoisting

There is a demand for Yale hoists wherever hoisting of an exact nature is required.

Made in capacities ¼ to 40 ton, there is a size to meet every need—whether it is in a small plant where the safe and economical handling of loads is essential, or in a great industry where the load problem is a vital factor.

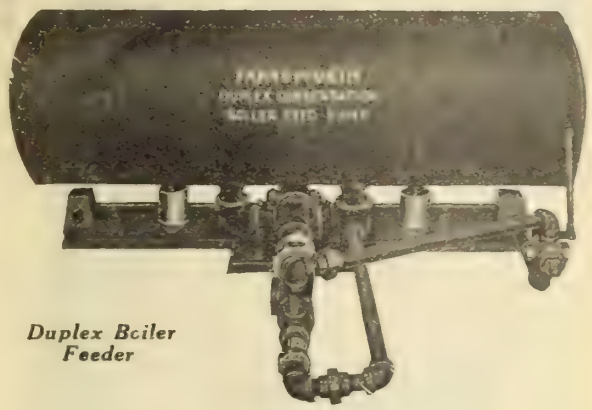
The Yale Spur-geared block holds the load positively, and the continuous chain guide prevents gagging at high speed of side pull. It lowers smoothly and rapidly.

Unusually large teeth reduce the strain and give an easy running gear system.

Each part of the Yale Block is carefully inspected as a unit and inspected again in the assembled block—which must pass a test load of 3,360 lbs. to the rated ton (50% overload).

Put your hoisting problems up to us.

Farnsworth



Duplex Boiler Feeder

One Canadian Factory has in use over $10,000 worth of Farnsworth Traps.

It claims a saving of 4,000 tons of coal per year. Another mill states that its saving will be 3,000 tons of coal.

The conservation of coal is a duty in which Farnsworth Traps will materially assist. The Farnsworth system provides for the return of all condensation to the boiler at the highest possible temperature.

Farnsworth Boiler Feeders are designed for installation above the boiler and will take high pressure condensation from heating systems, heated apparatus, dry kilns, etc., and deliver it to the boiler at temperatures beyond the capacity of any pump to handle.

The Canadian Government is asking the manufacturers to substitute other pumping apparatus for the inefficient steam pump. Farnsworth Traps will give the greatest saving of any pumping apparatus on the market.

Farnsworth Traps are made in several types to handle anything from the highest vacuum to high pressure steam.

Full information on request.

III IMPORTANT THINGS

TO CONSIDER ABOUT A SEPARATOR.

I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

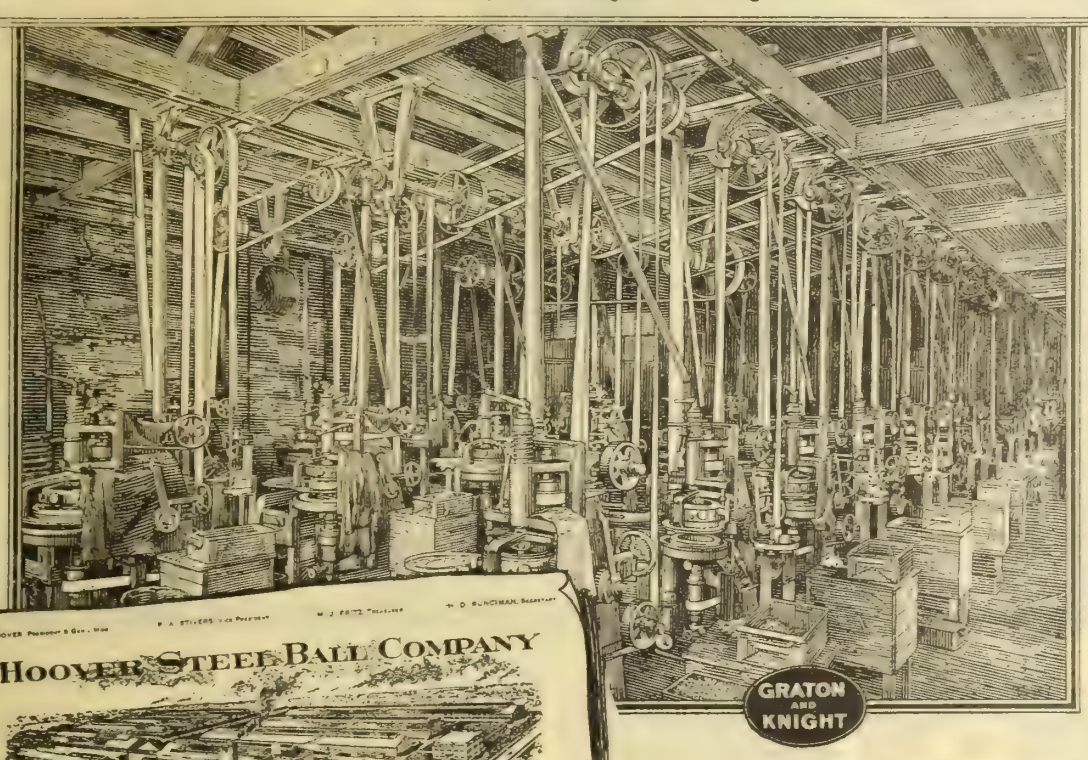
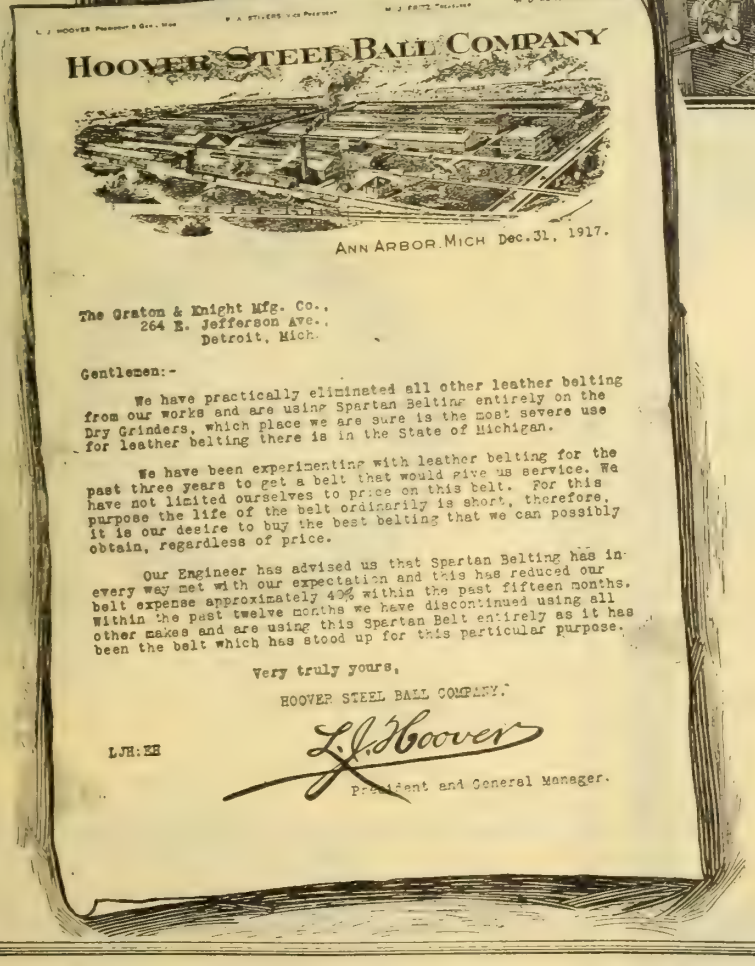
GRATON & KNIGHT

Standardized Series

LEATHER BELTING

Tanned by us for belting use





HOOVER STEEL BALL COMPANY

ANN ARBOR, MICH Dec. 31, 1917.

The Graton & Knight Mfg. Co.,
264 E. Jefferson Ave.,
Detroit, Mich.

Gentlemen:-

We have practically eliminated all other leather belting from our works and are using Spartan Belting entirely on the Dry Grinders, which place we are sure is the most severe use for leather belting there is in the State of Michigan.

We have been experimenting with leather belting for the past three years to get a belt that would give us service. We have not limited ourselves to price on this belt. For this purpose the life of the belt ordinarily is short, therefore, it is our desire to buy the best belting that we can possibly obtain, regardless of price.

Our Engineer has advised us that Spartan Belting has in every way met with our expectation and this has reduced our belt expense approximately 40% within the past fifteen months. Within the past twelve months we have discontinued using all other makes and are using this Spartan Belt entirely as it has been the belt which has stood up for this particular purpose.

Very truly yours,

HOOVER STEEL BALL COMPANY.

L.J. Hoover

President and General Manager.

LJH:EH

"the most severe use of leather belting" (see letter)

The advantages of standardized belting stand out *most conspicuously* in severe use, but they are *just as truly present* in less exacting conditions. Dollars are valuable whether you save them by tens or by hundreds.

The steps in acquiring transmission-wisdom run somewhat as follows: A poor belt is better than none at all. A good belt is better value than a poor one. But the scientifically right belt for each machine is the highest economy of all—and that is Standardization. It also explains why there is greater demand for Graton & Knight Standardized Series Leather Belting than for any other brand in the world.

Write for information about Standardization as applied to Belting.

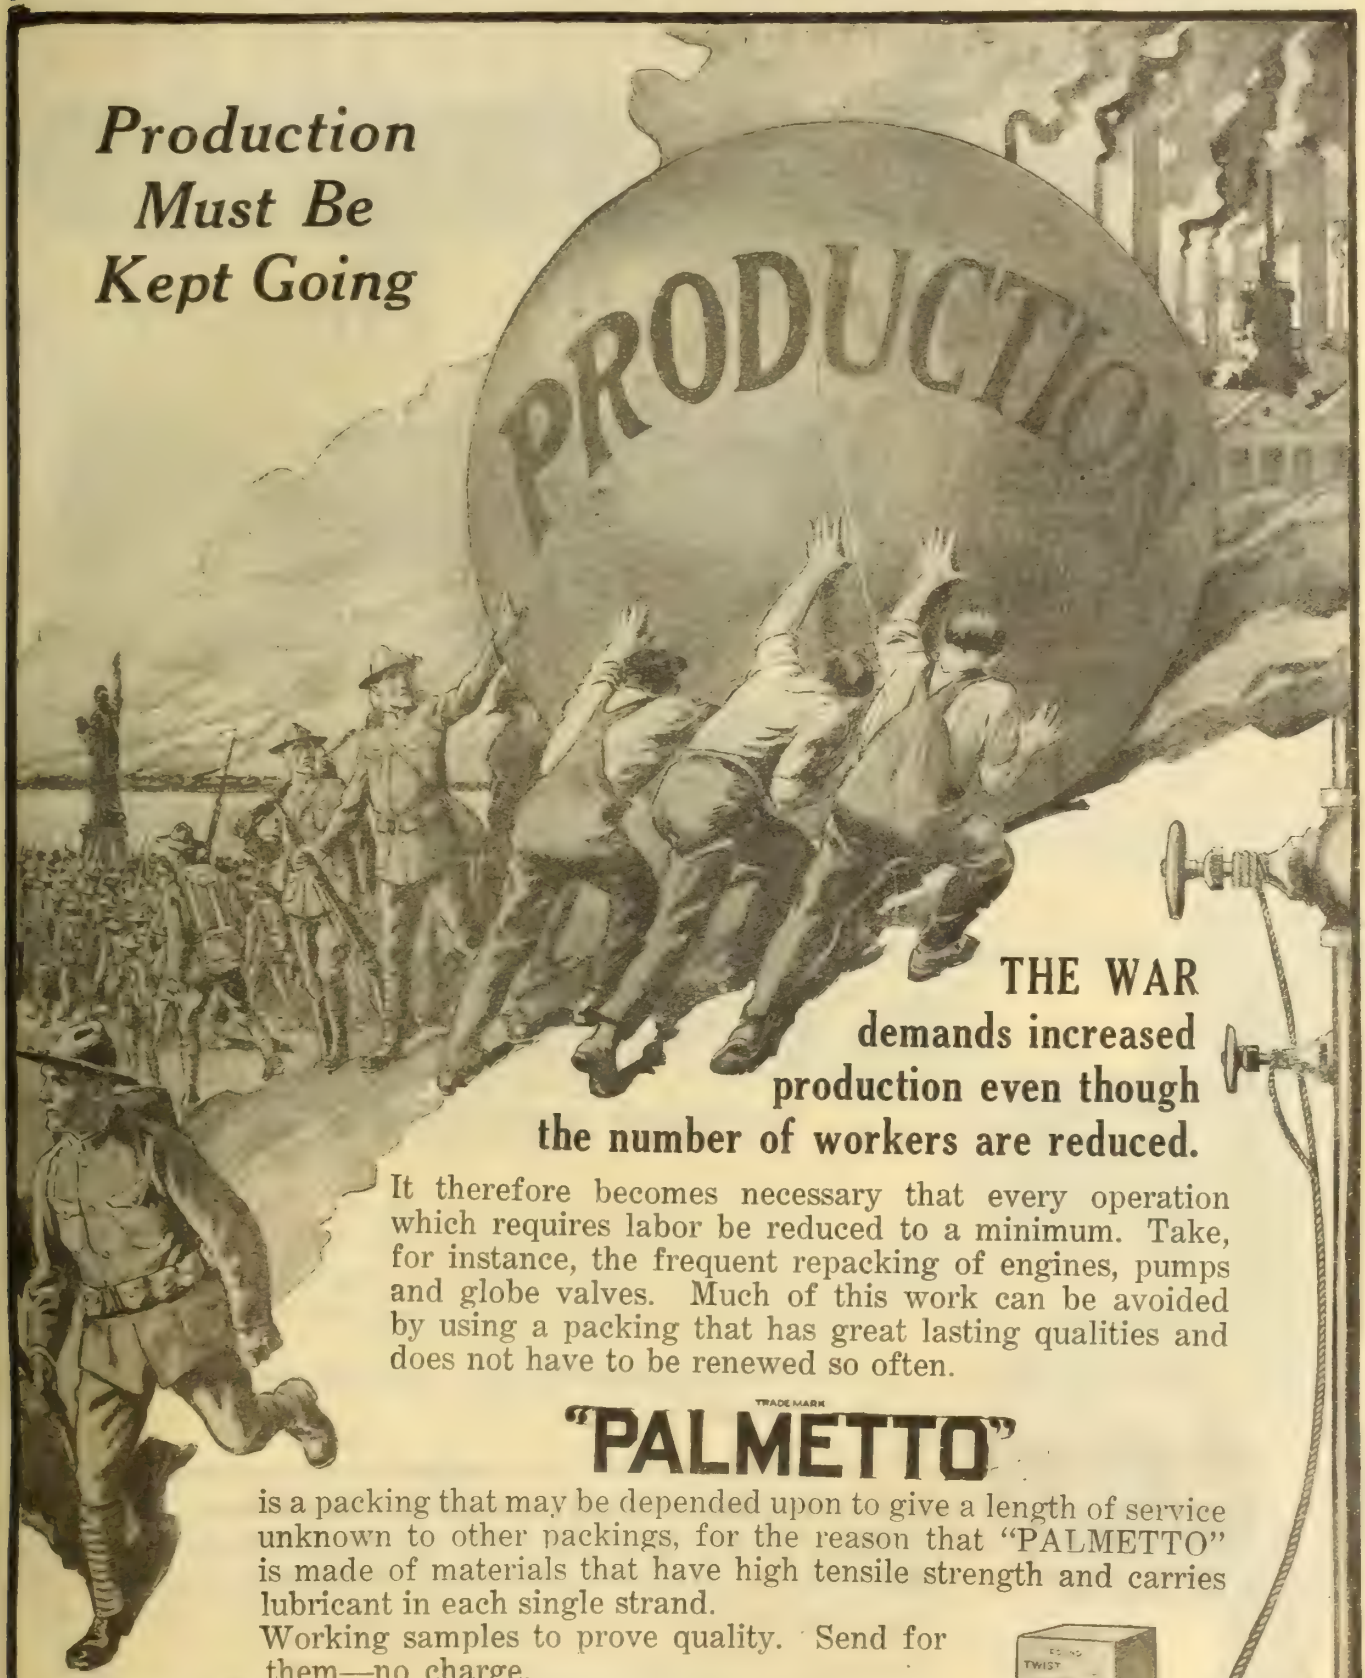
Production Must Be Kept Going



THE WAR demands increased production even though the number of workers are reduced.

It therefore becomes necessary that every operation which requires labor be reduced to a minimum. Take, for instance, the frequent repacking of engines, pumps and globe valves. Much of this work can be avoided by using a packing that has great lasting qualities and does not have to be renewed so often.

TRADE MARK
"PALMETTO"

is a packing that may be depended upon to give a length of service unknown to other packings, for the reason that "PALMETTO" is made of materials that have high tensile strength and carries lubricant in each single strand.

"You Will Yet Be Glad"

PRIVATE PEAT, who has sprung into fame through his books and extensive platform work, contributes an article to the August issue of MACLEAN'S MAGAZINE under the above heading. It is a cheery, optimistic message, contrasting conditions in 1914 with things as they are to-day. Private Peat, always a "headliner," is at his best in this article. But

Private Peat is only One of Many Features

In August MACLEAN'S there are half a dozen other writers with just as much "pull." Glance at this list:

"The Strange Adventure of the Man from Medicine Hat," a striking mystery story. By *Arthur Stringer*

"The Three Sapphires," a splendid serial story. By *W. A. Fraser*

"Keeping Border. in London," a fearless summary. By *Lt.-Col. John Bayne Maclean.*

"The Enemy Under the Earth," an article on the most terrifying phase of modern warfare—sapping warfare under the earth. By *Lt. C. W. Tilbrook.*

"Uplifting the Press," a satire on certain activities of the Dominion Government. By *One of the Uplifted.*

MACLEAN'S presents the vital and interesting things dealing with Canada—the most fearless criticism, the most entertaining comment, the biggest exclusive stories. Contributors to MACLEAN'S are the best writers and the most interesting personalities that the Dominion has produced. It is brimful of "features."

This book should be in the hands of every pump user. A postal will bring your copy promptly

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction*. Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs*. Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

Manufactured in Canada, under Canadian Patents, exclusively by the Engineering Specialties Company, Limited, 1080 King St. West, Toronto, Ont. 93-22

The Fire Brick Speaks

DON'T blame me, says the firebrick, if your settings fail too soon. For practically every premature setting failure is directly traceable to the use of an inadequate or improper mortar. Give bricks the protection of the right kind of a binder—not a fireclay, but a heat-resisting cement—face the brick with a good coating cement and your setting will outlast the ordinary kind many times over.

With every desired element of heat resistance, adhesion and durability, Johns-Manville High Temperature Cements afford a practical solution to all boiler setting problems. The bonding cements—applied as mortar between bricks—are so strong mechanically and so elastic that the contraction and expansion of furnaces will not rupture them or cause them to fall away. The coating cement which faces off the whole setting of the new brick protects the faces against spawling and cracking due to high heats or rapid temperature changes. And because of its resiliency it stays keyed to the setting despite expansion and shrinking.

Ask any branch to send you the High Temperature Cement Booklet. It tells which cement is suited to the working temperature of your furnaces and contains interesting data.

These Items Spell

QUALITY

FIRST COST + OPERATING COST + MAINTEN-ANCE COST + ADAPT-ABILITY + EFFICI-ENCY + EFFECT ON PRODUCTION + SATIS-FACTION

in Lamps

FIRST COST alone is **never** the criterion by which to gauge QUALITY – there is **no** "Quality" that does not contain **most** of these elements. LACO LAMPS contain them **all.** You may hesitate at the larger investment, but don't let the bogey of "First Cost" run away with your better judgment. If you **want** QUALITY in your purchase, you **must** pay for it. Analyze the LACO standard :—

First Cost – slightly higher than the best "ordinary" lamp.

Operating Cost—30 to 50% less current consumption per 1,000 hours for same quantity of light. One official test, for instance, showed 4 Laco Lamps burning 936 watts, gave the same light as 4 competitive lamps burning 1443 watts.

Maintenance Cost--25 to 40% longer life. (Replacement cost of 4 brands in same 1000-hour test averaged $12.68 – LACO none.) Guaranteed life of ordinary 1000 watt lamp is 1000 hours – LACO users frequently get two to three times this service; we can quote LACO Lamps that lived over 10,000 hours.

Adaptability—LACO Tungsten Lamps are made in sizes up to 60 watt; LACO Nitro are made in sizes 60, 100, 200, 250, 300, 350, 400, 500, 750 and 1000 watt—a LACO size for every need.

Efficiency—A clear, brilliant, colour-true, daylight ray.

LACO LAMPS

Effect on Production—
Government statistics have proved that the LACO quality of lighting will increase workers' earnings; one example alone showed 11.4 .

Satisfaction Is found in hundreds of letters from big operators in every line of business all over the country, telling their experience with LACO LAMPS. Read examples quoted.

Without cost to you — our nearest office will have official laboratory tests made of your lamps to prove our claims. Our lighting engineers will plan and submit an installation to meet your exact requirements in the best and most economical way.

Standard Bank Bldg., Vancouver, B.C.
Attention of Mr. Willard.

Dear Sir:—

We take pleasure in writing you of the excellent service given by Laco-Philips Lamps, and we are particularly impressed with the satisfaction our customers obtain, the percentage of defective lamps being extremely low.

We are also using your series lamps for street lighting and find that they give excellent satisfaction.

Yours truly,
(Sgd) Edmund E. Walker,
Sales Engineer.

The Robert Simpson Co., Ltd.

Toronto, Nov. 10, 1917

Laco-Philips Co., Toronto.

Gentlemen:

Our store has been equipped throughout with your LACO Nitrogen filled lamps since September, 1914, with very satisfactory results. During that time we have kept a very close record of the life of the various sizes in use, and the following is a list of the average hours burning:

500 watt	average	2788 hours
400 "	"	2232 "
350 "	"	1600 " "
250 "	"	2306 " "
100 "	"	1200 " "

We have also installed several of your Nitro Lamps in our Toronto and Regina Mail Order Buildings, along with your 40 and 60-watt Tungstens with equally good results.

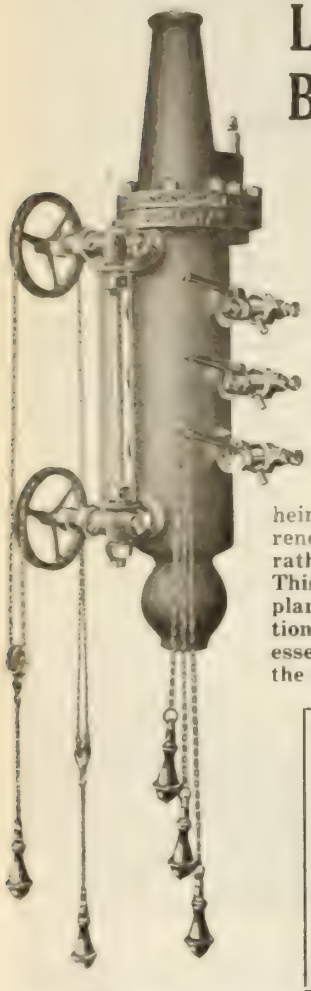
Proving their Economy



LUNKENHEIMER Boiler Mountings

are demonstrating their efficiency in power plants everywhere under the strain of increased production.

Correct designs and the high quality materials used peculiarly adapt them for high pressure steam service, and as a safeguard against interruption or delay every part is made to gauge and is interchangeable, permitting the repair or renewal of all parts.

Users should profit by the advantages embodied in Lunkenheimer Boiler Mountings and repair or renew a part when occasion requires, **rather than discard the entire device. This will contribute to economy in plant maintenance and the conservation of equipment, both of which are essentially necessary to our success in the war.**

OUR "WAR-PERIOD" APPEAL

Engineering Appliances are Prime War Essentials

Stocks of distributors and facilities of manufacturers must be adjusted to care for essential needs.

Lunkenheimer patrons are earnestly requested to assist in the common cause by confining their War Period specifications to requirements for essential plants, craft, vehicles or equipment.

Books for the Engineer's Library

Hawkins' New Catechism of Electricity

It contains 550 pages with 300 illustrations of electrical appliances; it is bound in heavy red leather, with full gold edges and is a most attractive handbook for electricians and engineers. One-third of the book is devoted to the explanation and illustrations of the dynamo, with particular directions relating to its care and management—$2.10 post paid.

Engineers' Examinations

By N. Hawkins, M.E.

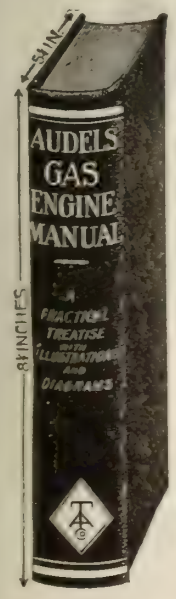
It presents in a condensed form the most approved practice in the care and managerment of steam boilers, engines, pumps, electrical and refrigerating machines, with examples of how to work the problems relating to the safety valve, strength of boilers and horse power of the steam engine and steam boiler.—$2.10 post paid.

Steam Turbines

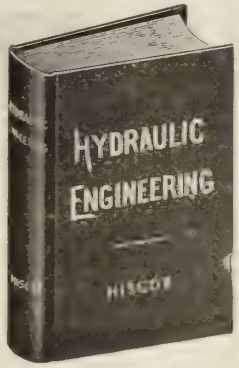
By Leland.

A reference work on the development, advantages and disadvantages of the steam turbine; the design, selection, operation and maintenance of steam turbine plants and turbo-generators. 135 pages. Illustrated.—$1.00.

Audel's Gas Engine Manual



A practical treatise relating to the theory and management of gas, gasoline and oil engines, including chapters on producer gas plants, marine motors and automobile engines.—$2.00.



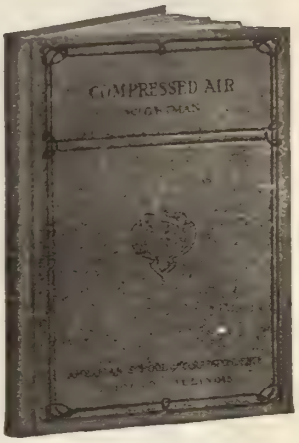
Hydraulic Engineering

By G. D. Hiscox.

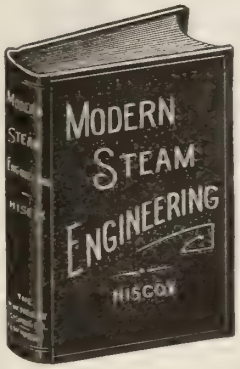
This comprehensive book of Hydraulics written by an experienced engineer, is a practical treatise on the properties, power and resources of water for all purposes, including the measurement of streams, the flow of water in pipes or conduits; the horse-power of falling water; turbine and impact water wheels; wave motors, etc. All who are interested in Water Works Development should have a copy. 320 pages, 305 illustrations. Price $4.15 post paid.

Compressed Air

By L. I. Wightman, E.E.



A reference work on the production, transmission and application of compressed air; the selection, operation and maintenance of compressed air machinery; and the design of air power plants. Illustrated.—$1.10.



Modern Steam Engineering in Theory and Practice

By Hiscox.

This book has been specially prepared for the use of the modern steam engineer, the technical students, and all who desire the latest and most reliable information on steam and steam boilers, the machinery of power, the steam turbine, electric power and lighting plants, etc. 450 pages. 400 detailed engravings.—$3.15 post paid.

Boiler Construction

By Kleinhans.

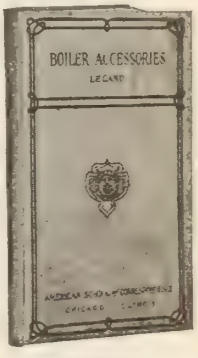
The only book showing how locomotive boilers are built in modern shops. Shows all types of boilers used; gives details of construction; practical facts, such as line of riveting punches and dies, work done per day, allowance for bending and flanging sheets and other data that means dollars to any railroad man. 421 pages, 324 illustrations, six folding plates.—$3.00.

Compressed Air, Its Production, Uses and Application. *By G. D. Hiscox, M.E.*

Comprising the physical properties of air from a vacuum to its liquid state, its thermodynamics, compression, transmission and uses as a motive power in the operation of stationary and portable machinery, in mining, air tools, air lifts, pumping of water, acids and oils and the numerous applicances in which compressed air is a most convenient and economical transmitter of power.—Price $5.15 post paid.

Boiler Accessories

By Walter S. Leland. S.B.

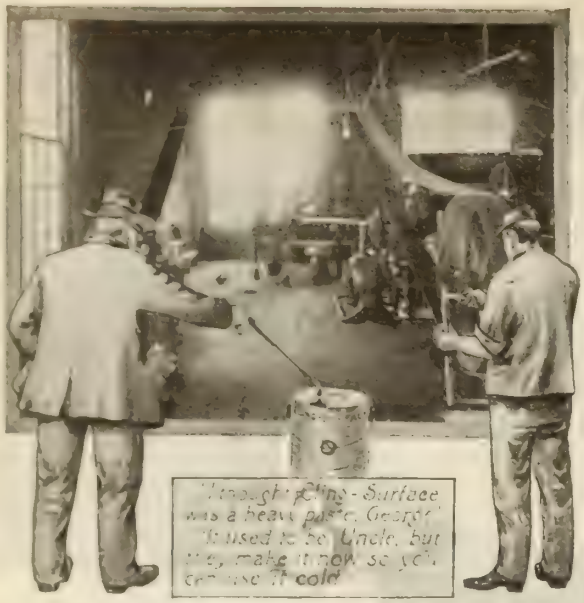


Assistant Professor of Naval Architecture, Mass. Institute of Technology, American Society Naval Architects and Marine Engineers. 144 pp., 80 illus. Cloth binding. A treatise giving complete descriptions of the various accessories of the boiler room and engine room essential to economical operation, such as evaporators, pumps, feed-water heaters, injectors, mechanical stokers, etc., with practical instruction in their use.—Price $1.10 post paid.

Technical Book Department

MacLean Publishing Company **143 University Ave., Toronto**

If any advertisement interests you, tear it out now and place with letters to be answered.



WE watched them run the big truck out of the yard; smoothly, almost noiselessly, it glided away. And in our minds we contrasted this with the noisy vehicle of ten years ago.

But almost any product can show improvement. Our own particular line has seen this change. The workman who objects to CLING-SURFACE "because it is hard to use" reminds one of the old lady who doesn't like automobiles because "they make so much noise." For the new semi-liquid CLING-SURFACE is perhaps easier to use than any belt dressing you can buy.

* * *

Changing it from the heavy paste of twenty years ago to the semi-liquid of to-day was not a simple problem. Not until 1915 were we ready to place it on sale. The preservative nature of CLING-SURFACE would not permit the use of any solvent, such as gasoline or turpentine. Nothing evaporative could be employed, as CLING-SURFACE must not oxidize, turn rancid or form sediment, for what it does in the open it will do in the belt, and there it should preserve and lubricate the fibres.

So, while twenty years ago it was necessary to heat the CLING-SURFACE, to-day (in ordinary temperatures) it is used cold.

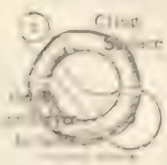
CLING-SURFACE is applied with a stick, say two feet long by one or two inches wide and half an inch thick, around one end of which is wound and wired a cloth bandage. At no time, therefore, is the operator in danger, for he is able to keep away from all moving parts.

* * *

CLING-SURFACE immediately stops the belt slip and removes any static electricity in the drives. Its continued use means mellow, pliable, waterproof and slip-proof belts, long-lasting and hard-working, saving you in power, oil, belting, coal, trouble, and men's and machines' time an amount annually which makes the price of CLING-SURFACE insignificant.

Ask us for the plan 10,000 firms have found successful. Our co-operation is free and our guarantee means something.

Remember, use CLING-SURFACE and you wont need belt dressings.



Cling-Surface Co.

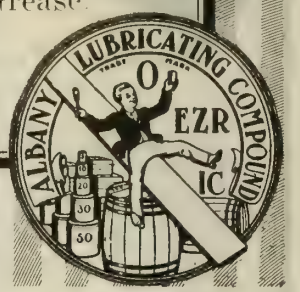
Buffalo New York

ALBANY GREASE

for over 50 years has given a perfect lubrication service in power and industrial plants throughout the world. It is used by large industrial companies as well as small concerns equally successfully on their mechanical equipment. Albany Grease will keep all bearings and gears operating cool and easy at all times. Send for samples—now, if you are not using Albany Grease.

Albany Lubricating Co.
708-10 Washington Street
New York, U.S.A.
Established 1868



The Gripping Power of a Giant

is the gripping power of "Spiro" couplings; in fact, they have a 50% greater gripping force than any other compression coupling. The tigher the pull on the two halves of the coupling the tighter the grip on the entire length and circumference of the sleeve on the shaft.

A spiral slot in the sleeve is a patented Bond feature that allows a tremendous gripping force to be applied. There are no keys to break or work loose and cause time and labor to be wasted in fixing it.

"SPIRO" Couplings Cannot Slip

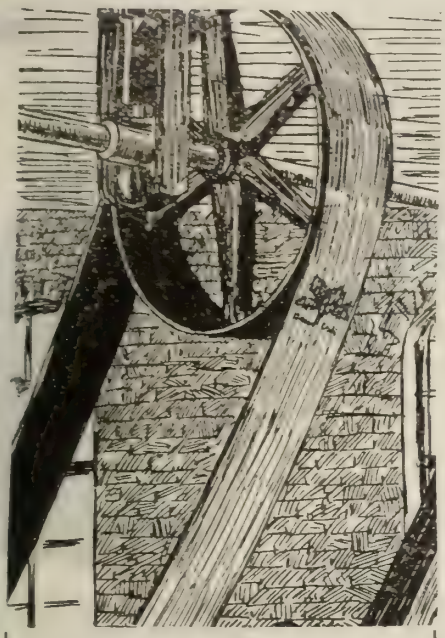
Whose Belting Turns the Pulleys in Your Plant?



It may be transmitting power at a power loss of 10 or 20 or 30 per cent., and still be a fairly good belting. But why should you lose 30 or 20 or even 10 per cent. of the power generated with high-priced fuel when a better belting

D. K. McLaren's
Genuine British Oak-Tanned
Leather Belting

would hold the loss to less than 3 per cent?

Simply because D. K. McLaren's Leather Belting is as nearly stretchless as a belting ought to be.

Simply because D. K. McLaren's Leather Belting does not slip.

Simply because D. K. McLaren's Leather Belting is made exclusively from close-trimmed butts of the finest selected hides, which are tanned the Genuine British Oak Method until extremely durable and pliable and tough.

For all the Facts write—to-day

Beware of Beltings that are *fairly good*

Particularly if you have tried many kinds

For you may conclude yours is as good as any

And once you do that you accept losses that you could eliminate

By using D. K. McLaren's Belting

Which has this Oak Leaf stamped upon it.

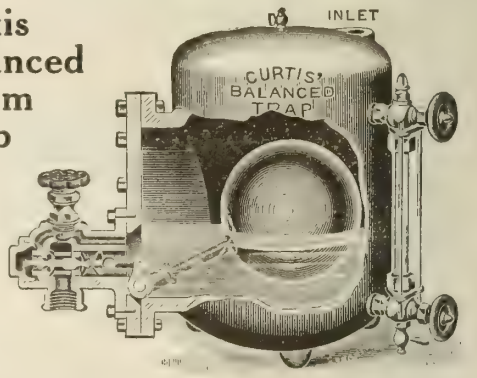
Curtis Balanced Steam Trap



Five Superior Features of the Curtis

1. A perfectly balanced valve.
2. An absolutely frictionless valve.
3. The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4. The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5. Each trap will operate perfectly on pressure varying from one to 250 lb.

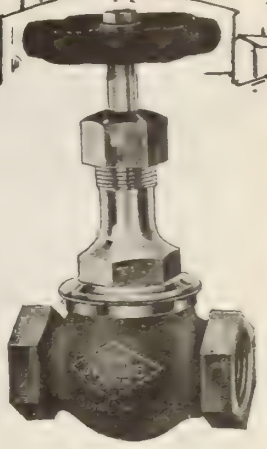
Jenkins Bros.

Valves



EVEN an apparently insignificant hiss of steam past a poorly seating valve will cause a material fuel loss per year. Multiply this figure by the number of valves in the average plant and the loss becomes appalling.

Dependable valve service is essential—more so now than ever before in view of the great scarcity of fuel.

No matter what the type of building or plant, the best valve service is necessary. Installing good valves at the start saves repair and replacement charges and the labor costs of re-installations later.

Whether you require valves for industrial plants, public or private buildings, **Jenkins Bros.' Valves** should be your choice. You can rely upon them under conditions where other valves would fail.

They will hold absolutely tight under steam, water, air and gas pressure for very long periods of service without attention. The design is heavier than the usual commercial standard pattern of other makes, enabling us to guarantee them for 175-lb. steam or 250-lb. water-working pressure.

All are fitted with renewable Jenkins discs made of a softer composition than the metal and which will seat perfectly tight in spite of inequalities or rough spots in the metal surfaces. When worn the discs may be replaced at trifling cost and the valves will become as tight as when new. The composition of the discs is varied to suit the particular requirements of each class of service.

Furnished in brass or iron body, in globe, angle, cross, check, Y or blow-off, hose whistle and other patterns.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914
With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID, Minister of Public Works and Highways
W. A. RIDDELL, M.A. Ph.D., Supt. Trades & Labour Branch

D. M. MEDCALF,
Chief Inspector of Steam Boilers.

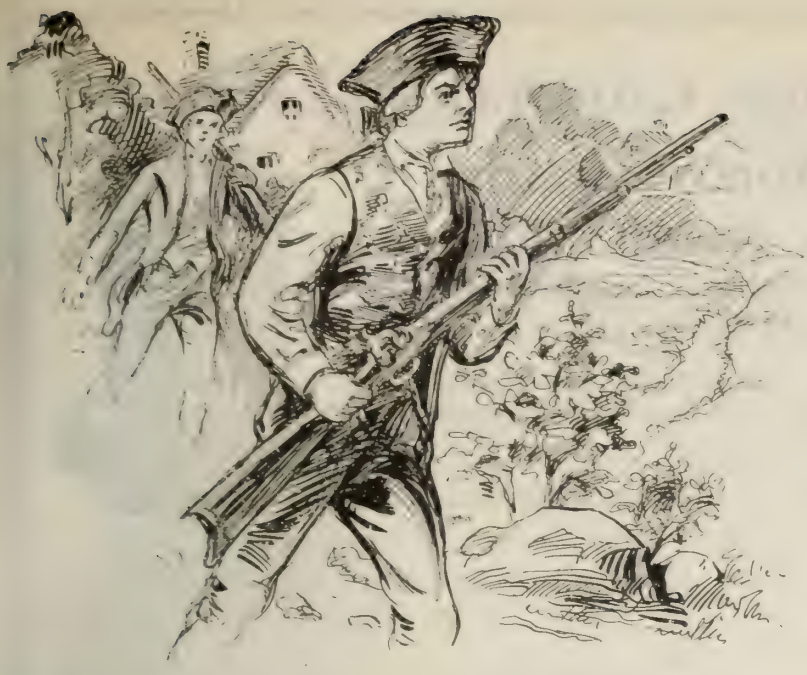
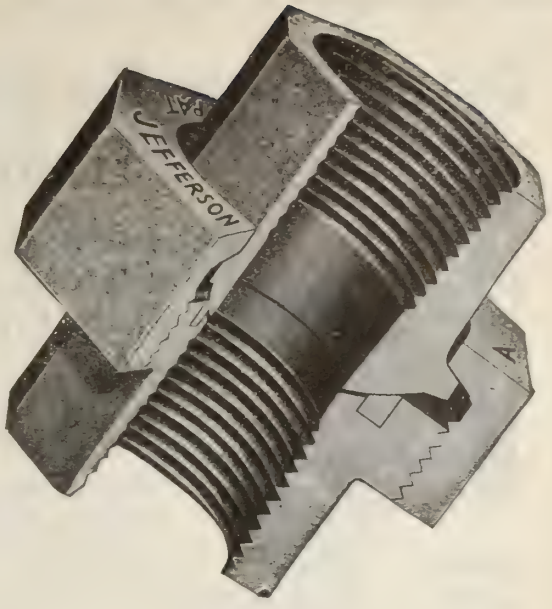
Mention This Paper When Writing Advertisers





Adding Fame to the Home of the Minute Man

Just as the colonial Minute Man typifies the real spirit of American freedom, so JEFFERSON UNIONS stand for freedom in their own line—freedom from annoying leaks and costly shutdowns.

JEFFERSON UNIONS

JEFFERSON UNIONS are more than just unions — they represent pipe-line efficiency and perfect union service. When you are tempted to install a "just-as-good" union, just consider that it costs just as much to install and when it fails you have to stand the added expense of replacing, besides the annoyance of leaks and power losses.

JEFFERSON UNIONS are built extra heavy, of high-grade, air-refined, malleable iron. They will not stretch or distort, no matter how hard they are set-up. The brass-to-iron joint cannot corrode, so that it is always an easy matter to take down a JEFFERSON.

Your jobber has JEFFERSON UNIONS awaiting your call. Ask him what he thinks of JEFFERSONS —he handles others and can tell you all you want to know. Our Catalog "UNIONS" shows our complete line.

Write to-day for your copy.

The Jefferson Union Company

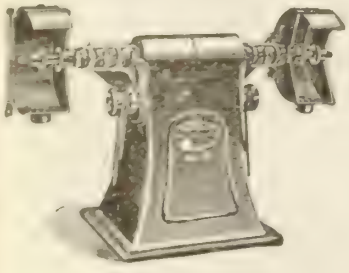
FOR POLISHING AND BUFFING



EXCELSIOR TOOL & MACHINE COMPANY,
Engineers, Founders, Machinists.
East St. Louis, Illinois.

Magnolia Metal Co., Sept. 4, 1917.

Gentlemen,—We use Magnolia Metal exclusively for lining the bearings of the spindles of our "Excelsior Double Arbor Labor Saving Polishing and Buffing Machines" with most satisfactory results.

These arbors run at speeds ranging from 1800 to 2300 R.P.M. and we have found the Magnolia lining to be greatly superior to ball bearings or to other grades of babbitt metals.

Among the concerns who commend our machines very highly is the FAVORITE STOVE & RANGE CO., of Piqua, Ohio, who installed twenty-six of these machines. In letter received from them two years after they say, in one paragraph:—

"The usual speed of the machines has been maintained and the boxes are apparently as good as when the machines were installed."

The wisdom of our selecting Magnolia Metal has been amply confirmed by our own experience as well as the favorable commendation of our customers.

We are pleased to be able to make this favorable report on Magnolia Metal.

Yours truly,
EXCELSIOR TOOL & MACHINE CO.,
T. T. PHILIPPI, President.

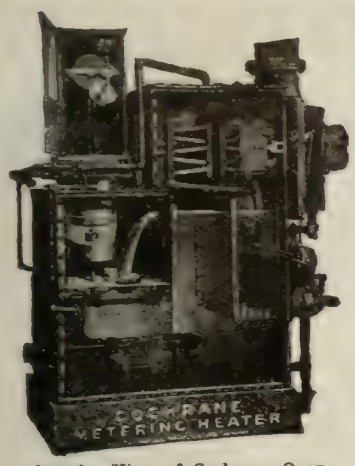
The Power House



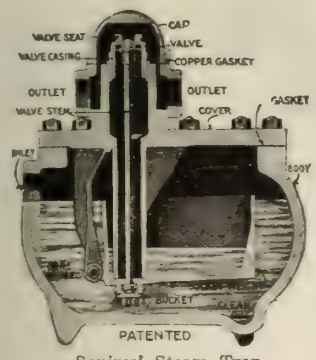
Interior View of Cochrane Open Feed Water Heater

Cochrane Heaters as used in Heating, Metering, and Softening water for boiler feed and other purposes.

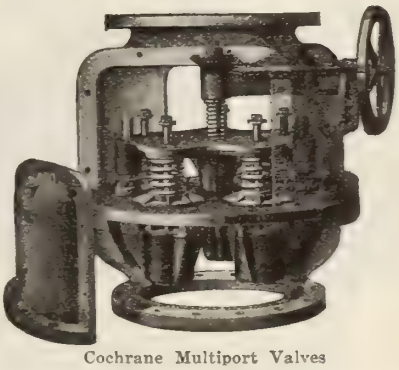
Cochrane Separators for removing water from live steam, water and oil from exhaust steam and compressed air.

Cochrane Steam Separator

Cochrane Multiport Safety Exhaust Outlet Valves are designed to release steam and prevent accumulation of pressure, and are the only valves of the kind absolutely free from sticking, pounding or overloading.



Squires' Steam Trap



Cochrane Multiport Valves

The merits of the Squires' Steam Traps have repeatedly been demonstrated in marine service, high pressure power plants, low pressure heating systems, on laundry machinery, steam separators, vulcanizers in rubber plants, dry kilns, drying rolls of paper machines, and other places where steam traps are required.

NOTICE

TO

Stationary and Hoisting Engineers

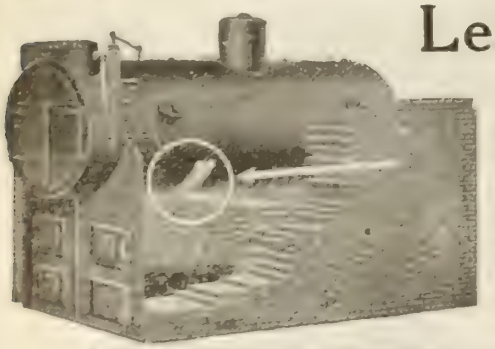
Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

HON. F. G. MACDIARMID, Minister of Public Works and Highways. W. C. McGHIE, Chairman of Board.

W. A. RIDDELL, M. A. PH. D., Superintendent, Trades & Labour Branch.



Leakage Stopped

Permanently stopped by the National Boiler Seam Protector, which anyone can attach in 30 minutes. It will also save your boiler from fire cracks, mud cracks and blisters. Write for long list of pleased users.

Free trial on request.

Starrett Speed Indicator

A GOOD SELLER

Every engineer needs a speed indicator and a tool bearing the name "Starrett" will be readily purchased by the man of experience.

Catalogue No. 21CD showing 2,100 fine tools sent on request.

THE L. S. STARRETT CO.
The World's Greatest Toolmakers
ATHOL, MASS.

The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH

Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.

Nut with Nut-Guards

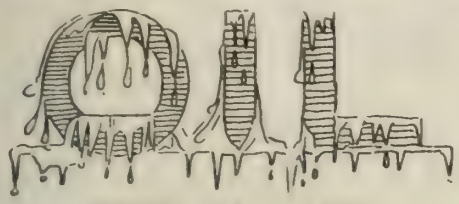
Anderson Pressure Filter

will save you one out of every two barrels of oil ordinarily used—and



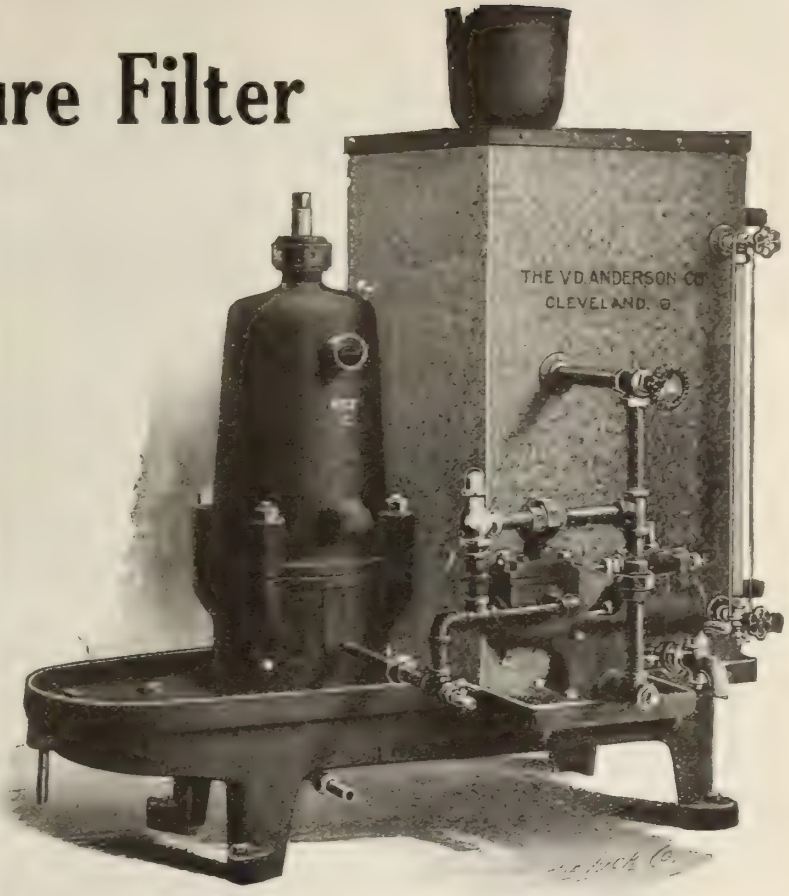
MUST BE SAVED

The Anderson Pressure Filter will make one barrel of oil do the work of two by cleansing and purifying the oil after use so that it can be used again and again on the finest bearings.

In wasted oil you pay the cost of an Anderson Oil Pressure Filter over and over—but you do not get it. Better pay for it once and thereafter experience what a really great economy it is.

Details in Booklet. Write.

The V. D. Anderson Co.
West 96th St., Cleveland, Ohio



In the big steel plants that are speeding up on war equipment for Uncle Sam.

ECONOMY renewable FUSES

insure electrical safety and cut annual fuse maintenance costs 80%. An inexpensive little "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.

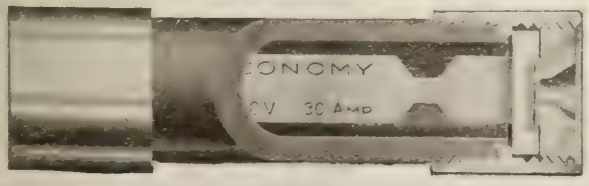
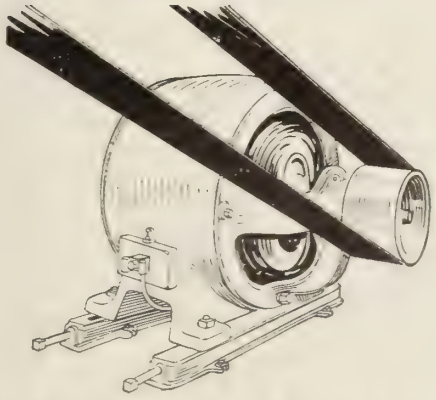
UNITY BLDG. - - MONTREAL

Manufacturers in Canada of S & B High Potential Fuses to 150,000 Volts.





LANCO BALATA BELTING

makes an

IDEAL BELT *for a* MOTOR DRIVE

On account of its very slight stretch it requires very little attention. As motor drive belts are frequently made endless to make silent running the small stretch is worth taking into consideration.

In addition to this it is a straight running belt; the tension is equally distributed over the whole width. Did you ever see a belt continually changing its position across the face of the pulley while running? This may be caused by not having the ends square but the chances are it is caused by unequal tension in different parts of the belt width.

This unequal tension does not occur in Lanco Balata.

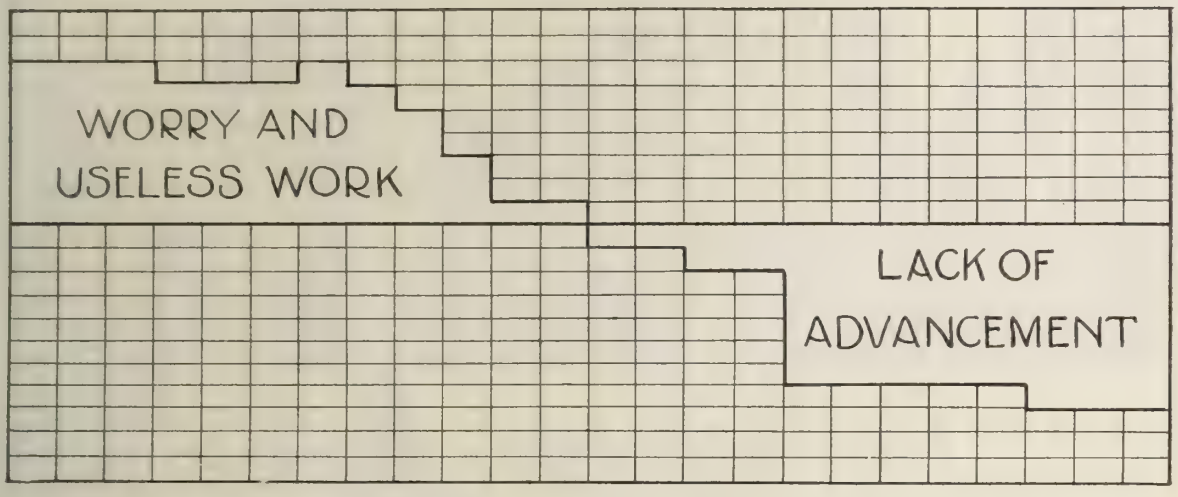
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary,

Before ordering that new conveyer, look over the advantages of this Improved Carrier, showing HOW OTHERS are safeguarding their Coal and Ashes Handling Machinery against carelessness.

There is only one way to wreck the Jeffrey Improved Carrier and that is by deliberate action. Each part and movement is constructed to safeguard your equipment against the carelessness of the operator. Unskilled labor can operate the Jeffrey Carrier.

Each bucket empties its material before receiving another load. There is no chance for material piling up on the floor and causing a serious wreck. There are many other devices for increasing the life of the chain joints, for reversing the buckets to obtain double service, etc.

Our New Bulletin, concisely describing the Jeffrey Carrier, has many clear views showing the carrier in action, while shop views of its parts give proof of its enduring qualities.

SEND FOR YOUR COPY—TO-DAY.

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CATALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.**

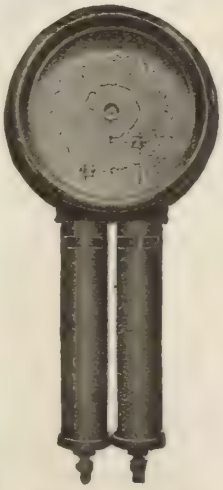
UEHLING WASTE METER

COMBINED

CO_2 AND TEMPERATURE RECORDER



Record of CO2 and stack temperature on one chart.

Does your fireman know how much fuel he is wasting? Do you know?

The Uehling CO_2 Recorder makes a complete 24 hr. record of your combustion efficiency and the CO2 indicator at the Boiler Front holds the fireman responsible.

Get more **Steam** per pound of **Coal** and reduce your annual fuel consumption.

CO2 Indicator for Boiler Front

Let us know the number and size of your boilers and coal consumed per year, upon receipt of which information we will be glad to send you full particulars.

Let us hear from you. We are pioneers in the manufacture of Indicators and Recorders for Power Plant purposes.

Send for our Bulletin No. 110.

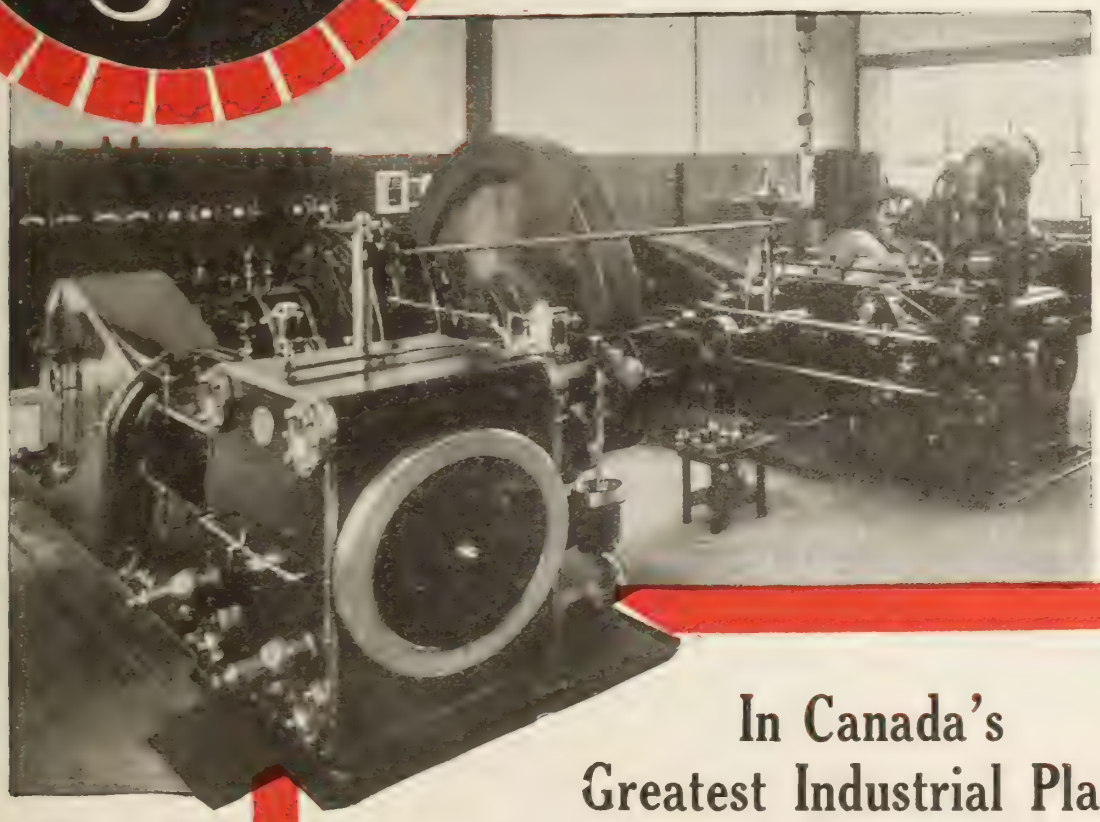
INGLIS Engines and Boilers



In Canada's Greatest Industrial Plants

The larger the plant, the easier the sale—or so we have found it. For in the personnel of almost all great plants there is at least one mechanical expert who invariably holds out for the highest type of power equipment. In the judgment of such men certain features exclusively possessed by Inglis Engines and Boilers are vastly more important than price or favor.

Without charge, without placing you under any obligation whatever, Inglis Experts will answer your questions, consider your special requirements, and recommend the equipment best suited to your needs.

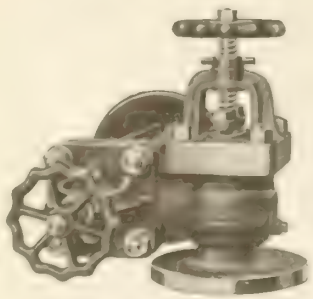
MORRISON'S

Steam Goods & Specialties

J.M.T. Reducing Valve.

Gem Ejector

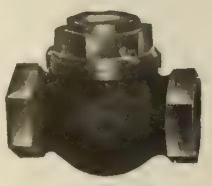


Beaver Combined Stop and Check Valve

Every Article Factory Tested and Guaranteed

Every article bearing the quality mark —J.M.T.—is warranted perfect. We set a high standard well on to half a century ago. Would we to-day break faith with the thousands using Morrison's Steam Goods? A thousand times no. It is their right to expect long, wholly satisfying service, just as it is our privilege to make Steam Goods and Specialties that so serve.

J.M.T. Injector



J.M.T. Check Valve

SOME OF OUR LINES

We'd like to tell you in detail about these:

- Stop Valves
- Check Valves
- Gate Valves
- Safety Valves
- Relief Valves
- Reducing Valves
- Steam Traps
- Injectors
- Ejectors
- Insperators
- Jet Pumps
- Steam Gauges
- Vacuum Gauges
- Ammonia Gauges
- General Boiler Mountings
- Gauge Board Outfits
- Lubricators
- Pipe Fittings
- Steam Whistles
- Engine Indicators
- Pipes, Tools, etc.

Pressure Gauges and Recording Instruments

The J.M.T. Line includes everything for the engine and boiler room—all approved by Provincial Government Inspection.

Let the quality mark—J.M.T.—guide you to the best.

Prepare Now

for the coming Winter

Everything points to an acute shortage of coal this winter. Take steps now to make your supply go as far as possible.

The Chief Engineer of Matthews-Blackwell Ltd., Toronto, says:

"I have been at the business twenty years and I've had at least **50% LESS TROUBLE WITH MY BOILERS** this year than ever before, and besides have effected a **GOOD SAVING OF COAL.** I say it's the Dean."

MR. ENGINEER, MAKE THIS TEST

Pick out the boilers in your shop which you believe perfectly clean and try the Dean Boiler Tube Cleaner on them.
This is what the chief engineer of the Matthews-Blackwell, Ltd., did and he was surprised at the amount of scale removed.

KEEP YOUR BOILERS SCALE-FREE AND REDUCE COAL BILLS

The Dean reduces coal bills from 9% to 35% depending upon the amount of scale in your boiler tubes.
The Dean cleans boiler tubes clean. It gets all the scale.
The Dean, because of its few and simple parts, takes out scale **faster** and **more thoroughly** than any other known methods; and its sturdy simplicity means long life, low upkeep cost and ease of operation

TRY THE DEAN CLEANER FREE OF CHARGE

Write a letter, "Send us a Dean on free trial, with the understanding that we are under no obligation to purchase it," and state type of boilers and exact outside diameter of tubes.

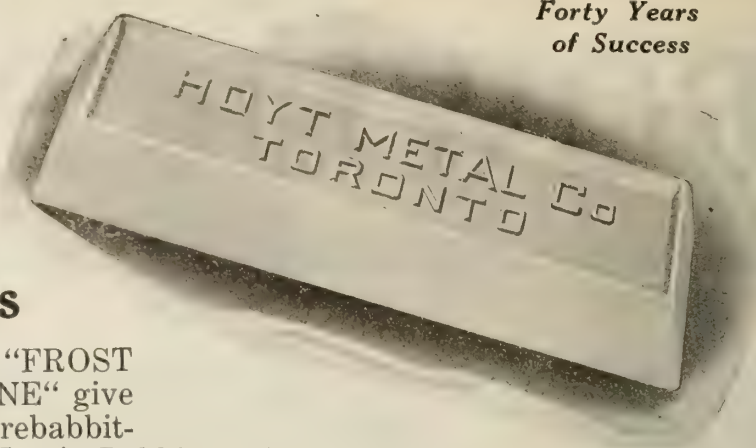
Hoyt Babbitts

Forty Years of Success



Will Cut Your Costs

Bearings babbitted with Hoyt's "FROST KING" or Hoyt's "NICKEL GENUINE" give extra long service before they need rebabbitting. Don't use common alloys. Hoyt's Babbitts will give you better satisfaction and cut your babbitting costs.

HOYT'S FROST KING—This general purpose babbitt has won its way into many of the foremost power plants of the world. It represents 40 years of success and has won the favor of Canadian engineers from coast to coast.

HOYT'S NICKEL GENUINE—This famous babbitt is recommended for use in gas engines, gasoline engines and all classes of marine engines. Especially adapted for automobiles. There is no better babbitt made for high-speed work.

Specify HOYT in Your Next Order for Babbitts

SPEED INDUSTRY'S WHEELS
IMPERIAL SMOKE-STACK LUBRICANTS
For Manufacturing, Mining and Milling
A wide variety of scientifically formulated lubricants, among which is the lubricant best suited to your needs. Our lines include such well and favorably known brands as:—
Atlantic Red Engine Oil
Bayonne Engine Oil
Standard Gas Engine Oil
Kearsage Engine Oil
Renown Engine and Dynamo Oil
Solar Engine Oil
Junior Red Engine Oil
Eldorado Engine Oil
Capitol Cylinder Oil
Beaver Cylinder Oil
Imperial Cylinder Oil
Shield Cylinder Oil
Ebony Cylinder Oil
Acme Cylinder Oil
Disc Cylinder Oil
Dominion Cylinder Oil
The proper lubrication of your power plant means increased output, and increased output means reduced production cost and more profit. Proper lubrication means more dependable power and many more years of service from each unit in your plant.
At no time in the world's history has 100% efficiency in plant operation been more necessary than now. There is nothing more essential to efficient plant operation than the use of proper lubricants.
We have competent Lubrication Engineers. Their services are free in assisting your own Mechanical Superintendent in determining the most economical and efficient lubrication for your power plant.
Write to our Home Office at 56 Church Street, Toronto, or to any of our Branches.

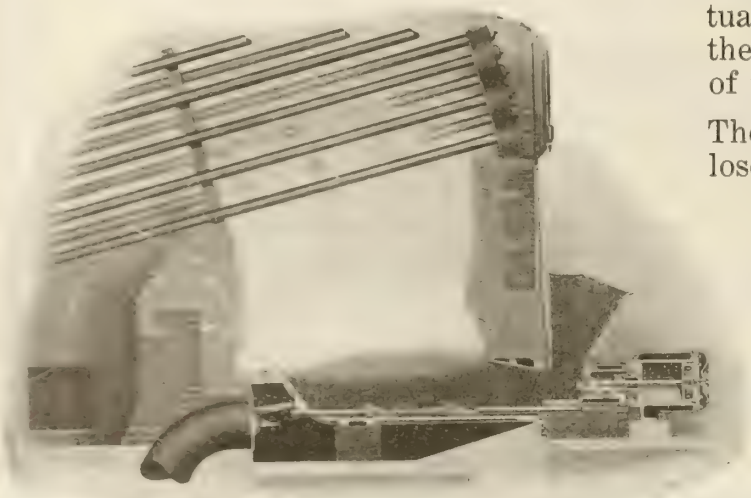
NO NEED TO WORRY *about fuel shortage*

You can do with 1/8 to 1/4 less fuel, and also save much labor and wages by installing the

JONES UNDERFEED STOKER



It is entirely automatic. Gives you a steady steam pressure, regardless of fluctuating loads, and scientifically gets **all** the energy out of coal by definite control of fuel and draught.

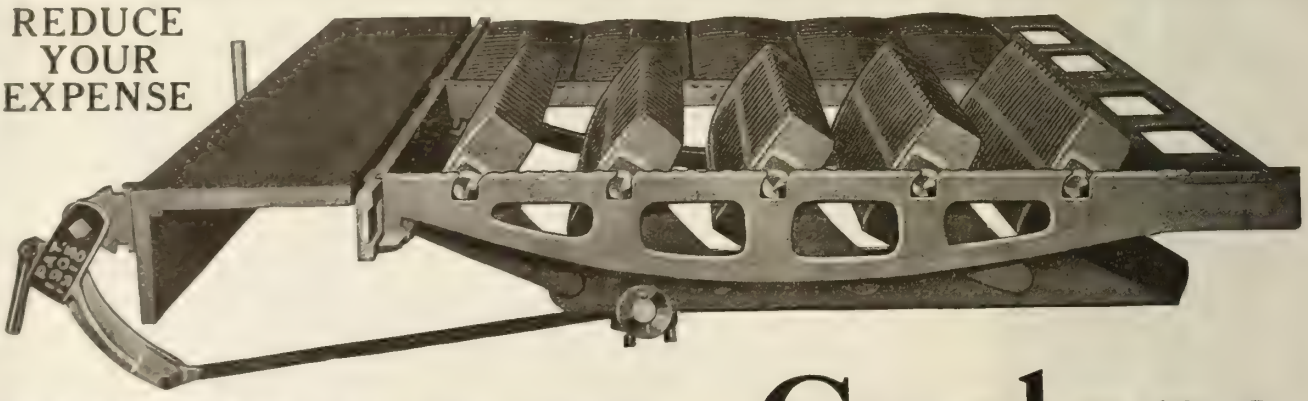
The simplest stoker built—no grates to lose fuel through—not a working part that moves in contact with the fire—no complicated mechanism.

Ask the users. We'll gladly put you in touch with a number of them.

Jones Underfeed Stoker Company, Limited

37-41 Britain St. - - TORONTO

REDUCE YOUR EXPENSE



SAVE COAL by using— Cyclone Grates

The design of Cyclone Shaking and Dumping Grate Bars ensures perfect combustion when using the lowest price fuel, such as screenings or low-grade soft coal.

60% Air Space and 90% Underdraught means no clinkers and no waste.

The new jarring, shaking movement sifts the worthless ashes through—but not a particle of good fuel.

Write for our 30 Days' Free Trial Offer now.

Every Barrel of **BOICO** The Quick Remover and Positive Preventive of Boiler Scale

SAVES A PILE OF COAL

It's such a heartless job trying to keep a boiler clean with ordinary compounds that comparatively few are always wholly clean. Consequently a good deal more fuel than need be is burned up on the grates. We claim for Boico that it removes absolutely all scale; that it positively prevents further formation of scale; that it does not carry over in the steam; that it does not cause foaming or priming; that it does not injure packing or valves in the slightest. You do not pay for Boico if it fails.

Write for our trial offer.

Anti-Clinker Shell Bar Grates

save coal. For one thing they prevent clinker formation. Half this total surface is air space—and abundant air commands perfect combustion. Let us tell you more in detail.

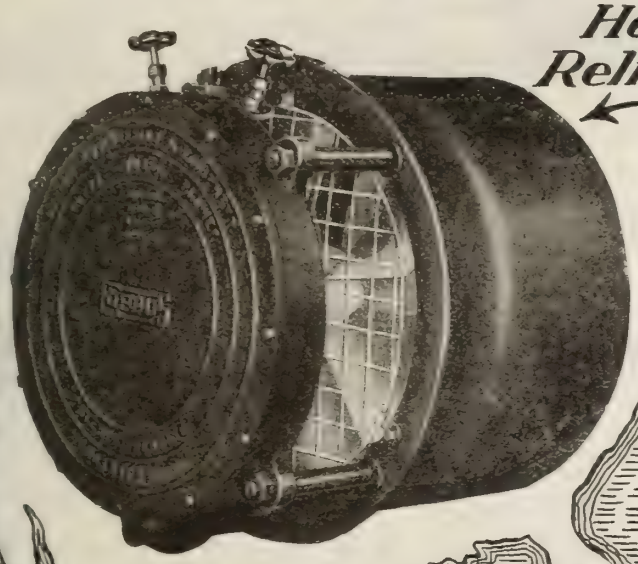
50 Million-ton Coal Shortage

Here's Relief



Coppus Turbo Blower

EVERY power plant in North America should be deeply concerned with the coal supply of the country. The situation is serious in the States, and what is true of the States is true of Canada. Here's what a recent bulletin issued by the United States Fuel Administration has to say:

"When it is popularly said that Munitions will win the war, or that finances will win the war, these are merely other ways of saying that the production of coal, and its application to the war in armaments, war ships, merchant ships, shells, rifles, tanks, submarines, airplanes or locomotives, will win the war. The war has created a demand upon this country for 100 million more tons of coal this year than is normally produced. Because of the car-shortage and the congested condition of the railroads, it will be impossible to increase the supply more than 50 million tons. The remaining gap of 50 million tons will have to be filled in by conservation in the industrial plants of America."

THE COPPUS TURBO BLOWER

places within the grasp of the power plants of Canada an opportunity to save their country thousands of tons of Coal.

Some of the best power plants in America have found it safe, sound and economical to make their boilers "come through" with maximum results, by the use of Coppus Turbo Blowers. There's no reason why you can't do the same.

There never was a time like the present when it behooved you to strive for big production, and economy in the fuel you use. And there's no better means to this end than through the use of Coppus Turbo Blowers.

You can easily run your boilers at 200 per cent. of rating, increase their efficiency, reduce your fuel expense, help your country solve the fuel problem and put money in your pocket. *Coppus Turbo Blowers* give you any amount of draft you want, where you want it and when you want it, and they do it with from 25 to 75 per cent. less steam for driving than any other blower on the market. Hurry and investigate it — time is precious these days.

Canada is dependent upon the United States for the greatest portion of her fuel supply. United States can't supply her own demands—and a shortage of coal in the States means a shortage of coal in Canada.

Thus it behooves all users of fuel to adopt every available means to help make good this shortage to avoid a menacing situation.

Every power house in Canada should have their boilers equipped with Coppus Turbo Blowers.

Insulation Most Important Point

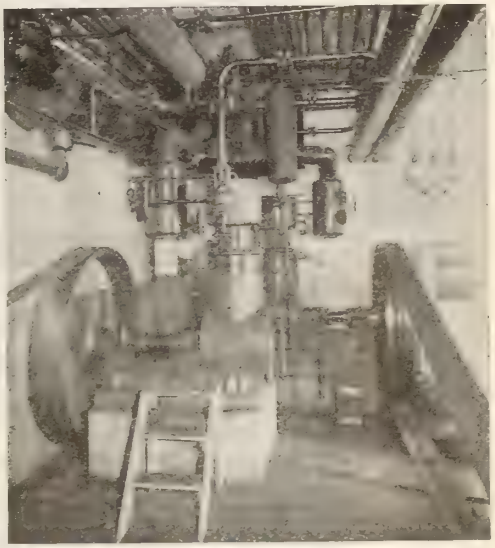
U. S. Dairy Expert Says

"In the economical operation of a refrigerating plant, the insulation is the most important point, and great care should be exercised in its selection and installation. All exposed piping between the expansion valve and the suction side of the machine should be carefully insulated."—John T. Bowen, Technologist, Dairy Division, U.S. Department of Agriculture.

Nonpareil Cork Covering

For Cold Pipes and Tanks

has thoroughly proved its superiority during the twenty years it has been on the market. It consists of pure granulated cork, compressed and baked in metal molds. The result is a covering which will save approximately 80% of the loss from bare pipes. Nonpareil Cork Covering is durable in service, too, because it will not suck in moisture by capillary attraction. Furthermore, the price is reasonable.



Brine lines insulated with Nonpareil Cork Covering, Peerless Creamery Company, Chattanooga, Tenn.

Armstrong Cork & Insulation Co.
504 McGill Building, Montreal, Que., Canada

Why not find out how much Nonpareil Cork Covering will save for you? Our 64-page book will tell. A sample of the covering, too, if you wish it.

Also manufacturers of Nonpareil Corkboard Insulation for all cold storage rooms; Nonpareil High Pressure Covering for steam lines; Nonpareil Insulating Brick for furnaces, boiler settings, etc.; Nonpareil Cork Machinery Isolation for deadening the noise of machine; and Linotile for floors in offices, residences, etc.

York Ammonia Valves and Fittings

assist materially in the conservation of ammonia.

Dependable Ammonia Valves and Fittings are of vital importance in every Refrigerating and Ice-Making Plant to-day.

YORK Ammonia Valves and Fittings are correctly designed, made under ideal conditions, subjected to an air test under water, and guaranteed tight under all usual working pressures.

A trial order will convince you of the superiority of YORK Valves and Fittings.

The Wisdom of Advertising When Oversold

ASK the "man in the street" to call the roll of talking-machine manufacturers, and he will name three almost certainly, four probably, and perhaps will go as far as five or six before his knowledge of the subject is exhausted. But ask him for the name of the leading concern in the industry and ninety-nine times out of one hundred you will get the same answer. The wisdom of the Victor Talking Machine Company's policy of continued advertising when the factory is oversold can be demonstrated by so simple a test as that.

Our neighbor, the *Dry Goods Economist*, points out that the talking-machine business is no longer a specialty proposition, requiring expert handling. The public at large is so thoroughly familiar with the idea of owning a machine and operating it that the department store can profitably enter the field and sell the line on a merchandise basis. And certainly there are plenty of available sources of supply. We counted the ads. of twenty-six different manufacturers in a single issue of a trade-paper, and that is by no means the complete roster. Some of them are also advertising to the consumer, others are not, yet the fact remains that the immense prosperity of the industry is attracting a multitude of concerns which intend to share it if they can. The leaders have done the pioneer work of educating the public to the talking-machine idea, and now let them look to their laurels!

The same thing has happened before in many other lines of business. We can name concerns which once were leaders, but which have gone down under the pressure of just such competition as is now threatening the talking-machine industry. Prestige meant little to them so long as they got the business; they felt that their standing was secure because the factory could not keep ahead of its orders. They regarded advertising as a useful means of getting more business, but why advertise when we don't need business?

There is little likelihood that leaders in the talking-machine industry will be deposed, for they have not advertised merely to "get business." Their advertising has represented in large part an investment in good-will—the laying up of a fund of public confidence which could be drawn upon whenever it became necessary. The wisdom of that policy will become more and more apparent as time goes on.—Printer's Ink.

POWER HOUSE

Refrigeration in the Packing House Industry

Trade Expansion Necessitates Increased Capacity—New Equipment Added Aids in Economical Handling of Packing-house Products

By W. F. SUTHERLAND, Associate Editor

CHANGES and advances consequent upon the demands of the war have taken place in almost every line of activity. This is true of the packing house industry no less than of those industries which one usually associates with the need for munitions.

Armour and Company have recently completed extensive alterations to their Hamilton plant, alterations which have added much to its effectiveness and efficiency in operation. Not only have these two desirable ends been achieved but a city wholesale market has been housed in a new building of attractive appearance, offering every facility for the transacting of city business. The improvements as completed involved reconstruction of part of the existing plant in addition to new buildings and increased refrigerating and power plant capacity. Engineering work in connection with the alterations was done by the Armour Company through their engineer, Mr. J. W. Carnegie.

Plant Description

The entire plant comprises four main buildings consisting of the new wholesale market and general offices, a building for general purposes, and a reconstructed block in which is incorporated a new loading platform or dock which not only provides a means of keeping all meats cool while being loaded into the cars, but which at the same time provides excellent facilities for icing the refrigerator cars used. In addition to the above a new cold storage building has been built which also contains the artificial ice making plant and ice storage.

Wholesale Market

The wholesale market, exterior and interior views of which are shown, contains the general and private offices necessary for the management of the plant, the cooling rooms for the wholesale meat storage, lunch rooms for the office staff and kitchen.

On the ground floor leading from the entrance hall are the general offices, while at the rear are the cooling rooms and at the side a shipping and loading dock. The cooling rooms include a pork cooler, beef cooler, packing rooms and smoked meat room.

The cooling rooms in the market are cooled on the brine system, two lines of 3-inch feed and return pipes being run from the power house. The coolers are held at 35 deg. Fahr. The pork cooler has 6538 cu. ft. capacity and 684 ft. of 2 in. piping, while the beef cooler has 11,170 cu. ft. capacity and 1,188 ft. of 2 in. piping. On the same floor is a general packing room 15 by 60 ft., another packing room 10 by 25 ft., and a storage for smoked meats 15 ft. wide by 25 ft. The packing and smoke rooms are at atmospheric temperature. The shipping dock at the wholesale market is equipped with overhead runways for handling the meat for shipping. The second floor is utilized entirely for general offices, while the third floor contains the lunchroom, smoking room and kitchen for the office staffs and departmental heads.

The wholesale market is connected to the main building by a long overhead viaduct, covered in. This serves as a passageway and is furnished with an overhead runway system for transporting meats to the market. The brine pipes to the wholesale market from the power plant are also carried in this viaduct.

ARMOUR & CO., GENERAL OFFICES AND WHOLESALE MARKET.

New Cold Storage Building

The new cold storage building recently completed is three storeys high with basement. Provision has been made in the strength of the footings, columns and bearing walls for two additional storeys at some future date. In the construction of this building a seven foot brick sewer was encountered in excavating for the footings and several footing had to be built so as to bridge this sewer and carry the load down on each side of it to the soil below and relieving it of all weight.

The basement is used for cooling export products, the first floor is a general storage, the second floor is a cooperage, while the egg storage is on the third floor.

NTERIOR OF COMPRESSOR ROOM, SHOWING WESTINGHOUSE MOTORS BELTED TO COMPRESSORS.

The ice storage and ice making plants are also located on the third floor. The ice storage adjoins the freezing tank and has a capacity of 13,700 cu. ft. This is sufficient to contain 150 tons of artificial ice. Four inch cork insulation supplied by the Armstrong Cork Company and placed by the Union Insulating Company of Chicago insulates the walls, while the floor is provided with 1½ in. mastic flooring and three layers of felt laid by the Johns Manville Co.

The freezing tank, which is operated under the flooded system, is 45 ft. 3 in. by 23 ft. 9 in. by 4 ft. deep. It contains 7,500 ft. of 1¼ in. piping and will hold 360 ice cans, each 11½ in. by 22½ in. by 44 in. deep, each cake of ice weighing 300 lbs. The capacity of the tank is 25 tons of ice daily. A hand operated Euclid travelling crane serves the tank, an electric hoist being provided for handling the cans. Two 20 in. agitators are provided for the tank, these being driven by a 5 H.P. C. G. E. induction motor belt connected.

The cans of ice are conveyed to a shipping tank where they are freed from the containers by hot water and are dropped onto a runway which passes through the ice storage. From this runway the ice may be placed in storage or sent through directly to the chute which carries it to the car icing plant.

The basement has a capacity of 73,675 cu. ft. and contains 3,070 ft. of 2 in. expansion piping. It is maintained at a temperature of about 36 deg. fahr. The egg storage has a capacity of 40,410 cu. ft. and contains 3,367 ft. of 2 in. expansion piping. Fans are installed in the egg storage for the circulation of air, a very necessary feature. All piping in this building was installed by the Vilter Mfg. Company, Milwaukee.

Car Icing and Loading Arrangements

In line with the work done in the building of that portion of the plant just described a loading dock has been built for the loading of all the products under sanitary and efficient conditions. This loading dock at the same time makes provision for the icing of the refrigerator cars used and as the loading platform is shut off from the tracks by heavy doors except when loading a moderate temperature can be maintained, a feature found advantageous in the handling of meats and other cold storage products.

The icing plant is connected to the ice storage by an overhead skid or runway. This enters the dock at the third floor level and the ice entering the dock goes into a Mechanical Manufacturing Company's ice crusher driven by a 20 h.p. the floor to the second floor level where it is received in ice buckets carried on an overhead runway and travelling out over the cars to be iced.

The rock salt used with the ice is unloaded from cars into a hopper and is conveyed to a salt room, adjacent to the crusher, and from which it is spouted into the ice buckets and mixed as required. The arrangement as installed is unusually complete and little manual labor is required for its operation. Five cars can be iced at one time.

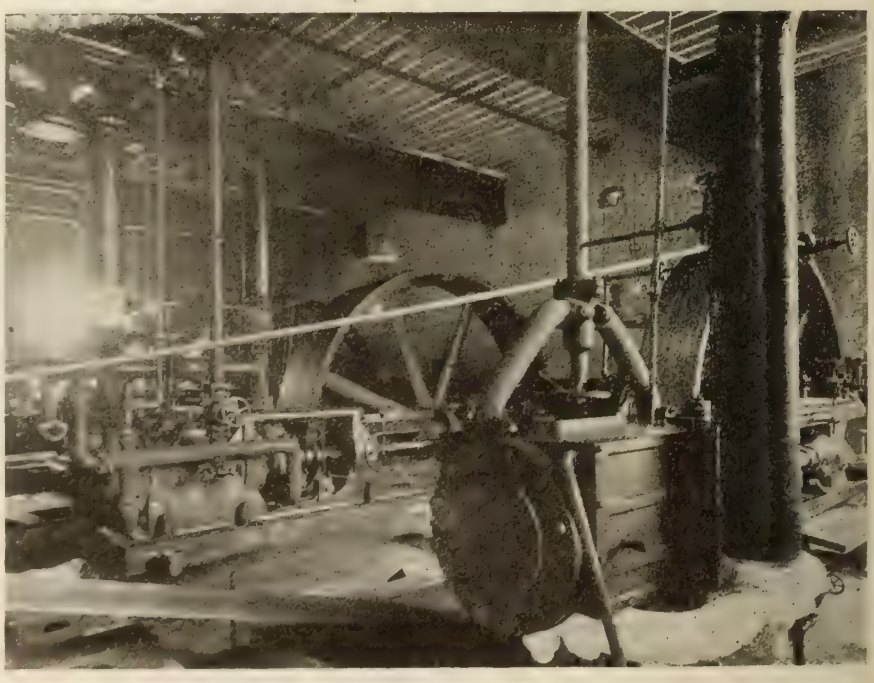
In a plant of this nature unusual attention must be paid to cleanliness and conveniences for the changing of clothing, etc., and the space over the icing platform and adjoining the crusher and salt rooms is given over to toilet and dressing rooms, lockers, showers and other conveniences for the accommodation of 300 men and 100 women.

Reconstructed Cold Storage Building

The reconstructed cold storage building contains three storage freezers and a sharp freezer. No. 1 freezer has a capacity of 13,734 cu. ft. with 2,013 ft. of 2 in. direct expansion piping. No. 2 freezer has a capacity of 12,653 ft. with 1,865 ft. of 2 in. expansion piping. No. 3 has a capacity of 9,826 cu. ft. with 1,580 ft. of 2 in. piping. The sharp freezer has a capacity of 12,373 cu. ft. with 4,179 ft. of 2 in. expansion piping. All the cold storage rooms are fitted with Jamieson doors and are insulated with 4 in. and 2 in. of nonpareil cork covered with plaster. The Union Insulating Co. of Chicago installed the insulation, while the expansion piping was installed by the Canadian Ice Machine Company, Toronto.

Refrigerating Plant

The ammonia compressers necessary for the operation of the refrigerating



COMPRESSAR ROOM, ARMOUR & COMPANY.

INTERIOR OF LOCKER ROOM.

system are installed in a separate building. These machines comprise the following units; one 50-ton Ball machine driven by a 100 h.p. Westinghouse motor; this motor is variable speed and speeds of 72, 64. 56 and 45 revs. per minute can be obtained; one 125-ton Vilter machine, driven by a 225 h.p. Westinghouse motor, having variable speeds similar to the one on the Ball machine; one 75-ton Huterman and Gaemer machine, driven by a 125 h.p. Westinghouse constant speed induction motor.

The resistance necessary for controlling the speeds of the variable speed motors are mounted on a covered platform supported between the power plant and the new refrigerating and ice storage building. This platform being open at the bottom and provided with a ventilator at the top provides a constant circulation of air for the carrying off of the heat generated.

Boiler Plant

As may be gathered from the description of the compressor room the power requirements of the plant are all met by purchased power. This does not do away with the necessity of using steam for many of the packing house processes, cooking, rendering, scalding, etc., and a boiler plant is installed, furnishing steam for these purposes.

The 100 horsepower Robb Engineering boilers are installed in a double setting with hand-fired grates; the boilers are horizontal return tubular and have grate areas of 52.5 sq. ft. A third unit is being installed, steel work, foundations and breeching being provided for an additional unit at a later date.

This third unit is of 125 h.p. capacity and is manufactured by the Casey Hedges Co. of Chattanooga, Tenn.

The feed water pumps are of Deane horizontal duplex type, 6x4x6 in. The pumping installation also includes a brine circulating pump, a booster pump and a centrifugal pump for the condenser. The feed water is heated to an approximate temperature of 210 deg. Fahr by a No. 7 Stillwell heater. A steam pressure of 100 lbs. is carried.

Perhaps the most interesting feature of the boiler plant is the periodical tests which are run at intervals of two months. These tests are quite painstaking and serve as an excellent check on plant performance, a feature which not only is of benefit to the company but is also of value to the country at large in view of the widespread interest and necessity for fuel conservation. The tests are conducted by the engineer in charge, Mr. Eustice, and results are tabulated in the Chicago office and returned together with the results of similar tests in the other plants of Armo and Company. This feature, needless to say, lends considerable interest to the test and furnishes the engineer with an incentive to keep plant performance up to a very high mark.

While the boiler capacity of the Hamilton plant is limited, excellent results are obtained, comparing very favorably with those obtained in the larger plant at Chicago and elsewhere.

The following data obtained from the report of the last test is of interest, being indicative of the general boiler performance.

Bituminous coal of a heat value of 12,375 B.T.U. as weighed was used carrying 14.87 per cent. ash; 644 lbs. coal were used per hour evaporating 5,732 lbs. of water from and at 212 deg. per hour.

The evaporation reduced to a tabulated basis is as follows:

Table No. 1—Evaporation

	Lbs.
Water evaporated actual per lb. fuel as fired	8.13
Water evaporated actual per lb. dry fuel.	8.13
Water evaporated F and A 212 deg. per lb. fuel as fired	8.90
Water evaporated F and A 212 deg. per lb. dry fuel	8.90
Water evaporated F and A 212 deg. per lb. combustible	10.4

In table number 2, given below, the most noticeable feature is the up-take temperature, that of 402 deg. Fahr being maintained as an average during the test.

Table No. 2—Temperatures

Average outside temperature	62
Average inside temperature in boiler room	70
Average temperature up take	402
Average temperature feed water	125
Average temperature steam	336.6
Average temperature of throttling calorimeter	223
Quality of steam	96.6

ARTIFICIAL ICE TANK. STRIPPING ICE TANKS.

CAR ICINB PLANT. VIEW SHOWS ICE CANS RECEIVING ICE FROM CRUSHER.

During each test gas analyses are taken periodically. The samples are drawn from the combustion chambers and the up-take and, as will be noticed, no variation between these samples was obtained, a CO_2 percentage of 13.4 resulting in each case and indicating a tight boiler setting.

Table No. 3—Gas Analysis

1st pass	CO^2	13.4
	O	3.2
	CO	0
Flue	CO^2	13.4
	O	3.2
	CO	0

The heat balance figured from the data obtained during the test showed a boiler efficiency of 69.78 per cent. and a furnace and grate efficiency of 87.90.

ELECTRIC AUTOMATIC ELEVATOR DISPATCHER

By Frank C. Perkins.

THE accompanying illustration shows an automatic novel electric elevator dispatcher, the basic principle of this device being such that it can be used for any duty to be performed at exact and recurring intervals.

In order to keep the elevators moving this machine was designed to aid the elevator starter in his job. The single tap of the bell gives the elevator man his cue to start both from the first floor and from the top on the return trip. It is pointed out that machines always eliminate that human element, which causes railroad wrecks, minimizes efficiency and adds to the petty annoyances of daily business life-fallibility. Nothing distracts the machine from taking care of its job—many things make the human "forget."

The electrical elevator starting machine speeds up the cars, keeps them continuously on the move, and makes possible regular service to all the floors, things every building manager has done his best to accomplish, but which he has never been able to achieve to his complete satisfaction.

It is held that hitherto there has been no known device for the purpose of marking time intervals other than the clock. By this is meant that no device for the performances of a certain duty at stated intervals has been invented except with a clock as the actuating mechanism and even such devices have been limited to individual units. The multiple unit system is primarily a device that has as its purpose the doing away with the uncertainties of the operation of elevators, or rather the starting them by means of human agency, and the substitution therefore of a system entirely automatic in its work.

The prime force of this device is the small motor having an extension shaft with a worm gear at its extremity, which actuates through a train of gears within the square box a large disc. This disc in turn moves the lesser discs, which being on shafts move together. At the end of each lateral shaft is a small commutator contact-piece on which a sliding brush contact plays. At each revolution of this commutator the circuit is broken and a single stroke bell in the elevator shaft, both top and bottom, is sounded.

It is stated that spacing by turning a thumb nut so that the smaller discs are brought either in or out from the periphery of the large disc, with the result that the time elapsing for the run of the elevator from top to bottom of the elevator shaft, or vice versa, may be extended or curtailed as desired. Each of these small discs are independent of the others and may be on different time spacings; but the essential point is that the small discs have been set and the time intervals established, the respective times are absolutely maintained, no variation being possible.

It will be noted that the lower portion of the cabinet contains a motor generator for the lowering of a regular line voltage to voltage required to ring the bells. Bull's eye lights on the front or face of the cabinet light in unison with the ringing of the bells. The advantage of this is that the engineer, in whose room the cabinet is placed, sees the operation of the elevator in effect and can keep a check on the work of the elevator drivers.

It is claimed that the gains of the building managers by the use of this device are many. It provided increased car mileage and acceleration of the movement of the cars by reason of the immutable signaling system established. There is a reduction of the peak load by reason of the fact that cars cannot bunch. No two cars may be at a given point at one time and hence it will be seen that the passengers must be more evenly distributed between the cars. Inasmuch as all charges for electricity and the cost of steam power are based on the maximum demand, it will readily be seen how important this is.

It is maintained that in one building in Chicago in which the device is used, it was found possible almost from its installation to cut the use of pumps

AUTOMATIC ELEVATOR DISPATCHER.

down from two to one, with a consequent saving of coal from $8 to $12 per day. This is a system in which a number of units may be controlled by one centralized moving device in absolute har

Port Colborne, Ont.—The International Nickel Co. of Canada began to treat matte at the new refinery at Port Colborne recently. A large quantity of matte from the Copper Cliff smelter has been shipped to the refinery, and supplies of all kinds are now on hand, and one furnace is in operation.

Genius is the art of taking infinite pains.—Carlyle.

PULVERIZED FUEL COMBUSTION

By Frank C. Perkins.

THE use of pulverized coal is said to make practicable the highest efficiency obtainable in boiler operation. It makes coal burn like a gas, with a flame, the physical and chemical character of which is regulable—a flame that may be elongated or shortened, thus placing the zone of highest temperature where needed; a flame that may be made oxidizing, reducing or neutral, as occasion may require.

The coal is burned as pulverized, thus there is no storage of the powder with its attendant hazard. Artificial drying of the coal is not necessary if the supply be sheltered from rain and snow. Where the pulverizer is used, it is wholly a furnace question whether a dryer should be installed. It is not at all a pulverizing or storage question. The labor is reduced to a minimum and slack coal at low cost yields it last b.t.u.

The pulverizer described herewith approaches the subject of coal burning from the theoretical side, and, therefore, pulverizes the coal to an impalpable powder, and surrounds each of its minute particles with the amount of air which will furnish just the required oxygen. The fineness of the pulverization may be regulated by attention to the dampers which control the movement axially of the air within the machine. If that movement is slow, the centrifugal force keeps all coarse particles at the periphery, and they are drawn from one chamber to the next only as they become reduced to such fineness as to permit the axial current to overcome the centrifugal force, but if the movement axially is rapid, it in part overcomes centrifugal force and draws through the machine a coarser grade of material. The pulverizer utilizes air separation on thoroughly scientific lines. Powdered coal and air in regulable proportions are intimately mixed in the pulverizer, and the mixture reaches the furnace instantly it leaves the pulverizer.

The mixing operation commences at the feed end of the pulverizer, where coal and air enter together and the pulverizing and the mixing go on together until the mixture leaves the pulverizer having the appearance of a cloud of smoke. This impalpable powder, with its theoretical requirement of air, is conducted through a suitable pipe directly from the pulveriser to the furnace. There is no coal pulverized except for instant use. Every minute particle of coal is in the furnace and ablaze within one second from the time it leaves the pulverizer, and within one additional second is completely consumed. In a majority of cases the time is less than one-half a second in each case.

A condition is, therefore, created and maintained, in which each particle of coal is separated from every other particle when it enters the furnace, and no opportunity is offered for the powder to pack or for the particles to adhere one to another, but each particle is enveloped in air and, therefore, in contact with the oxygen necessary for combustion. Thus, this system is emancipated from not only the dryer, but the powdered coal conveyer apparatus, the storage bins, the mixing chambers and the feeding mechanisms with the power units required for the several operations. There is nothing between the coal bunker and the furnace except the pulverizer, its motor, and a plain pipe connection. When the mixture of coal and air reaches the furnace combustion proceeds with great rapidity, with no smoke, no carbon in the ash, no CO in the flue gases, and only a trace of O, and no appreciable excess air is admitted to reduce the temperature of the products of combustion.

There is no opening of doors, no intermittent firing, no banked fires, no delay in meeting a sudden overload. The pulverizer consists of three or more interiorly communicating chamber of successively increasing diameters, in which revolve paddles on arms of correspondingly increasing lengths. The separate chambers are, in fact, separate pulverizers on a single shaft, each succeeding pulverizer having greater diameter and, therefore, greater speed at its periphery and greater power for fine grinding, each receiving and treating the product of the preceding chamber and passing it on to the succeeding chamber for still further reduction.

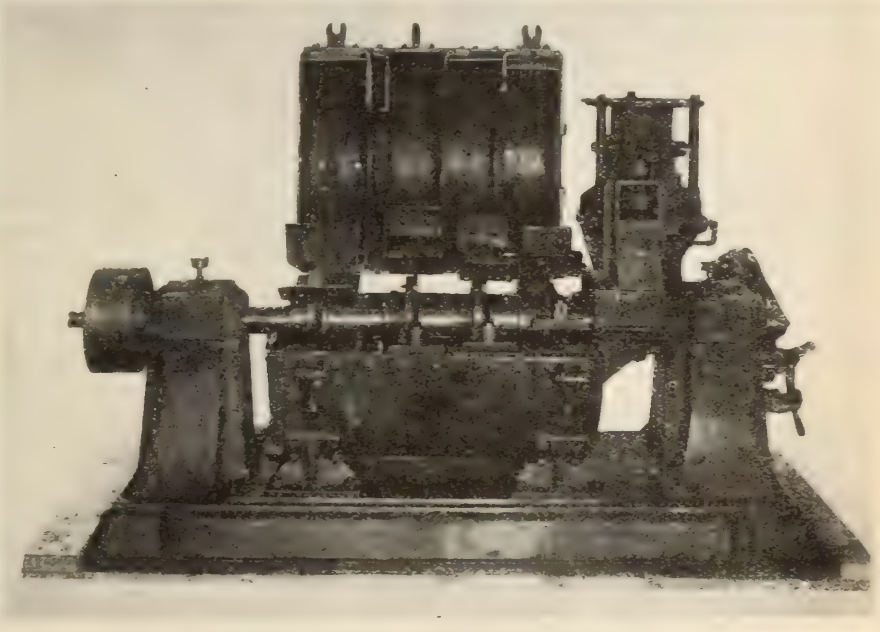
An additional chamber contains a fan, the function of which is to draw the finely pulverized material successively from one chamber to the next, and finally, to deliver it through a pipe connection to the furnace under the impetus of a forced draft. The separate pulverizers and fan are enclosed in one steel cylinder. A regulable feed mechanism accurately controls, and at the will of the operator varies the quantity of coal admitted to and delivered by the machine.

The feed mechanism is exact and uniform in its operation, and is easily adjusted to meet even minute variations in the fuel requirement. Two inlets in the feed mechanism admit the air required for fine grinding. An auxiliary inlet between the last work chamber and the fan, controlled by a damper, admits such additional air as is required for combustion. The air dampers with the feed mechanism give perfect regulation of the flame within a wide range.

Construction

The pulverizer runs at constant speed and the operator's attention and work is limited to observation of his fire and regulation of the feed mechanism. One operator can attend to a number of installations. The pulverizer is dustproof, and is arranged for easy repair to the parts susceptible to wear, the cost of which is small. The paddles, which are subject to the greatest wear, are of cast manganese steel, heat-treated for ductility and to resist abrasion and are reversible. The shaft is of 40 carbon open hearth steel.

The spiders are in one piece, cut from ½-inch steel plate, and are bolted to cast iron hubs with shearing bolts of a size to withstand ordinary strain, but to shear with extraordinary and unusual strains. The linings are of steel plate, and there is a relief opening in the bottom of the first chamber for the automatic removal of any iron or other metal that may accidentally enter the machine.



COAL CRUSHER AND PULVERIZER.

This equipment may be located either in front of the furnace or at either side, or above or below, and may be set with the discharge opening toward the furnace or away from it, or in any intermediate position as convenience may dictate, and the drive may be by belt or by direct connected electric motor. The connection between the pulverizer and the furnace is usually a galvanized iron pipe from the pulverizer discharge to the furnace. No additional feeding or mixing apparatus could serve any useful purpose, for the powdered coal and air are intimately mixed in the pulverizer. The furnace end of the discharge pipe is made of such size and shape as the furnace condition requires

Power Plant Management; Control of Combustion Losses

Economical Use of Coal as Essential to the Winning of the War as is Greater Production at the Mines—Both Tend to Minimize the Coal Shortage

By ROBERT JUNE

IN our prosecution of the war the biggest and most important factor is the coal problem. Some may disagree and claim that it is ships and munitions, but the production of these depends upon coal, and like it or not, we are faced by a very real coal shortage that is bound to limit our output of supplies to a greater or less extent.

I say greater or less extent, because we have an opportunity to overcome much, if not all, of the shortage through the elimination of waste by the institution of better methods of combustion. In order to get at a thorough understanding of our problem let us see what happens when we throw a shovel of coal into the boiler furnace.

The raw materials of combustion, coal and air, are composed of a number of elements which must be taken into consideration in arriving at an understanding of the cause of waste. Coal consists largely of carbon, hydrogen, oxygen, sulphur and earthy material or ash. Air is made up principally of oxygen, nitrogen and water vapor. In the furnace these elements behave in the manner shown in Table I.

TABLE I.

1 Name of Element	2 Chemical Symbol	3 What happens in the furnace.	4 Combines with Oxygen to form	5 Amt. of Oxygen required to burn	6 Amt. of air in lb. required to burn 1 lb.	7 Heat developed by complete burning of 1 lb. in B.T.U.
[illegible]	C	burns	CO-2	2.66	11.57	14,000
[illegible]	H	burns	H-2O	8.0	34.80	62,000
[illegible]	O	doesn't burn	....	....	.....	.....
[illegible]	N	doesn't burn	.....	....	.....	.....
Sulphur	S	burns	SO-2	1.0	4.35	4,050

If carbon and oxygen are brought together at a high temperature, 12 parts of carbon will unite with 32 parts of oxygen to form 44 parts of carbon dioxide, which means that 2 2-3 pounds of oxygen are required to burn 1 pound of carbon dioxide.

Our only source of oxygen is the air, which is composed of 23 per cent. of oxygen and 77 per cent. nitrogen by weight, so that to supply one pound of oxygen to the coal we must use

$$\frac{100}{23} = 4.35 \text{ lbs. of air}$$

$$\frac{77}{23}$$

which includes = 3.35 lbs. of nitrogen.

In order to burn completely one pound of carbon, 2 2-3 pounds of oxygen are required and 3 2-3 pounds of carbon dioxide are formed.

As 3.35 pounds of nitrogen are introduced with every pound of oxygen, it follows that for 2 2-3 pounds of oxygen, 8.92 pounds of nitrogen are used.

The result of burning one pound of pure carbon in air is therefore

3.67 pounds of CO_2
8.92 " " N

12.59 " " flue gases.

As the ash in coal requires no air, and hydrogen is present in but minor quantities, the theoretical amount of air required to burn carbon is approximately that required for the complete combustion of coal—that is 12 pounds of air in a perfect furnace.

In the actual furnace it is necessary to supply more than the theoretical amount of oxygen. The percentage of excess air depends upon the size and character of the coal, kind of furnace and grates, depth of fuel bed, method of firing, draft and other variables. But it may be set down as an axiom that where much over 40 per cent. of air is used for combustion there is something radically wrong.

The cooling effects of various percentages of excess air are indicated in Table II.

TABLE II.

Percentage Excess Air.	Theoretical Temperature of Combustion.	Loss of Temperature due to excess of Air.	Loss expressed in terms of Percentage.	Relative boiler capacity, assuming 40% excess air as normal attainable practice or 100%.
0	5132° F	0	0	....
10	4710	422° F	8.2	....
20	4352	780	15.2	....
30	4044	1088	21.2	....
40	3777	1355	26.4	100%
50	3543	1589	31.00	93.5%
60	3333	1796	35.0	88.2%
70	3152	1979	38.6	83.0%
80	2988	2144	41.4	78.5%
90	2840	2292	46.7	74.5%
100	2705	2927	47.3	70.0%
125	2419	2713	52.9	63.0%
150	2188	2944	57.4	56.6%
175	1997	3133	61.1	51.5%
200	1837	3295	64.2	47.0%

So far as concerns the efficiency of steam production it would make no difference what the temperature of the fire was, or whether 12 pounds or 120 pounds of air were used for each pound of coal, so long as the fuel were completely burned and the boiler surface large enough to absorb all the heat in the gases. If we had an ideally perfect boiler that could absorb heat from gases until they were cooled down to air temperature we would not care how much air had been used to burn the coal, nor what the temperature of the gases was, because all their heat would be absorbed. Unfortunately it is not only impossible but impracticable to build boilers of this kind. Heat cannot be absorbed effectively by a boiler from flue gases which are much cooler than 500 to 600 deg. Fahr. Furthermore, this temperature is usually required to produce the necessary draft, and unless the quantity of gas is kept down to a small volume the draft will be impaired because of the friction loss due to the resistance of fuel, boiler and chimney.

With the actual boiler then, it makes a great deal of difference whether 12 pounds or 120 pounds of air are used to burn one pound of coal. In one case 13 pounds of hot gas are going up the chimney, and in the other case 121 pounds. These hot gases are the chief "waste product" of the boiler plant or steam factory and they constitute the largest item in the total waste of 40 per cent. occurring in the average plant. Evidently the loss due to heat carried away by this waste product is reduced by taking only the minimum amount of air. But just as the factory manager must keep tab on his waste in order to eliminate it, so must the engineer measure the amount of his waste product in order to take steps towards its reduction. The amount of chimney gases per pound of coal is obtained by measuring CO_2 or carbon dioxide; the heat in each pound of these gases is measured by their temperature. We will consider briefly all of the important causes of loss in a boiler plant and point out their extent and, if possible, how each loss may be reduced.

[illegible] This is the third in a series of articles on Mr. June's Power Plant Management [illegible] problems, use of instruments, mechanical stokers, etc. [illegible] and [illegible] management of

Heat Losses in Burning Coal

A boiler, in order to utilize entirely the heat of combustion of the fuel must be free from radiation and leakage losses, the fuel must be completely oxidized and the products of combustion must be discharged at atmospheric temperatures. Commercially such conditions are unobtainable, hence complete utilization of the heat generated is im-

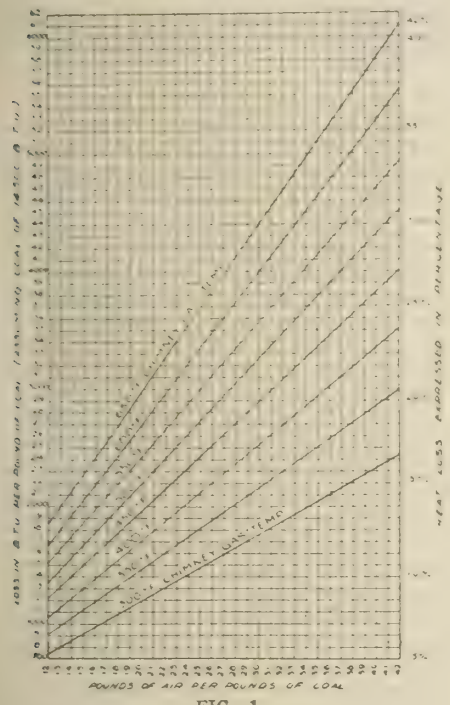


FIG. 1

possible. A boiler which utilizes 83 per cent. of the heat value of the fuel is exceptional and an average figure for very good practice is not far from 77 per cent. The various losses including the heat utilized by the boiler constitute the commercial "heat balance." The losses considered are:

1. Loss in the dry chimney gases.
2. Loss due to incomplete combustion.
3. Loss of fuel through the grate.
4. Superheating the hygroscopic moisture in the air.
5. Moisture in the fuel.
6. Loss due to the presence of hydrogen in the fuel.
7. Unburned fuel carried beyond the combustion chamber in the form of soot or smoke.
8. Radiation and minor losses.

Some of these losses are preventable, others are inherent and cannot be avoided.

Loss in the Dry Chimney Gases

This loss depends upon the type and proportion of the boiler and setting and upon the rate of driving. It is usually the greatest of all losses. The amount of heat carried away under varying conditions is shown graphically in Fig. 1.

It will be noted that the magnitude of this loss depends upon the air dilution and the temperature at which gases are discharged. Flue temperatures less than 450 deg. Fahr. are seldom experienced except in connection with economizers, and as the air dilution is ordinarily well over 40 per cent., the loss from this cause may range from 8 to 40 per cent. of the total heat generated.

The amount of this loss can be cut down by reducing the weight of the heat-bearing gases, by only admitting to the furnace the minimum practical amount of air, by preventing leaks in the furnace setting, and by reducing the temperature of the gases by keeping the fire surfaces of the boiler clean through the use of mechanical soot blowers.

CO_2 analysis apparatus is invaluable in determining this loss and furnishing a basis on which to lessen it.

Loss Due to Incomplete Combustion

If the volatile gases are not completely oxidized as when the air supply is insufficient or the mixture of air and gases is not thorough, some of the carbon may escape as CO_2. Some of the hydrocarbons may also pass through the furnace without being burned. The presence of even a small amount of CO_2 in the flue gas is indicative of appreciable loss, as will be seen from Fig. II.

If the furnace is properly designed these losses may be reduced to an almost negligible quantity by careful operation. With a good and even fire bed having a thickness suited to the effective draft, only traces of CO, hydrogen, etc., should be found. If the losses exceed 2 per cent. there is something wrong and pains should be taken to find out whether the trouble is due to poor design or careless firing, so that it can be eliminated.

Loss of Fuel Through Grate

In average practice the unconsumed carbon found in the ash pit ranges from 15 to 50 per cent. of the total weight of dry refuse, depending upon the size and quality of coal, type of grate and rate of driving. This loss of fuel runs from 1.5 to 10 per cent. or more of the total heating value. Although various attempts have been made to assign an average percentage to this loss they have been without result or value. Numerous tests of recent mechanical stoker installations have indicated losses ranging from 1.5 to 5 per cent. of the heat value of the coal at normal driving rates.

This loss can and should be reduced by proportioning the grate openings to suit the size of coal burned, careful handling of the fire, and, when practicable, the substitution of free burning for caking coals.

Less Due to Superheating Moisture in Air

This loss is in the main a minor one, ranging from 0.2 to 0.4 per cent., except on hot, humid days or at plants located at points of excessive rainfall or near the seacoast. As it cannot be controlled, except as excess of air is controlled, it is not discussed further.

Loss Due to Moisture in Fuel

Moisture in the fuel represents an appreciable loss in economy if present in large quantities, since the heat necessary to evaporate it into superheated steam at chimney temperature is lost. Firemen occasionally wet coal to assist coking or reduce dust, but moisture thus added necessarily reduces the theoretical furnace efficiency.

Under certain conditions wet coal may give a higher evaporation than dry coal, that is through a purely mechanical action the moisture may assist in packing the coal, thus reducing the loss through the grate, or in cases of thin fires, reduce air excess. The occasions when the application of the hose to the coal pile is warranted are of limited frequency, however, and firemen should be under strict instructions never to apply water without the specific consent of the boiler-room foreman.

It follows from what has been said, that coal known to be high in moisture content should not be purchased without adjustment of price to compensate for lowered efficiency.

Losses Due to Presence of Hydrogen in the Fuel

That part of the hydrogen in fuel, which is in a free state burns to water, and in so doing liberates 62,000 B.T.U. per pound. Unfortunately all of this heat does not become available for producing steam since the water formed by combustion is discharged by the flue gases as superheated steam at chimney temperature. This loss is inherent. With anthracite it approximates 2.5 per cent. of the heating value, and with bituminous, 4.5 per cent.

Loss Due to Visible Smoke

The loss due to smoke is very visible, but it cannot be weighed or measured and is generally over-estimated. Smoke consists of carbon in a flocculent state and ash mixed with the products of combustion.

The losses due to visible smoke seldom exceed one per cent. It must be remem-

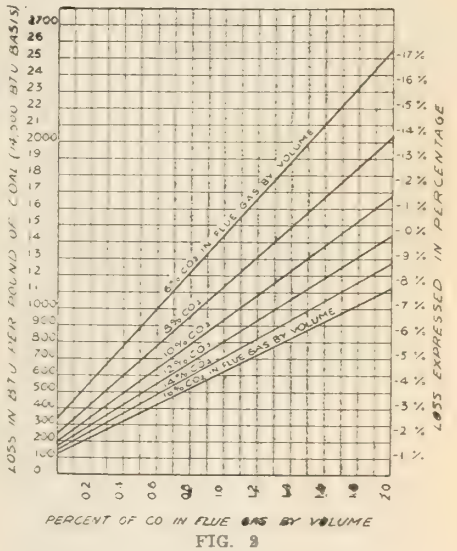

FIG. 2

bered in considering this loss that a smoky chimney does not necessarily indicate an inefficient furnace. Paradoxical as it seems, a smoky chimney may be much more efficient than one which is smokeless. That is, a furnace operating with minimum air supply may cause dense clouds of smoke and still give a higher evaporation than one made smokeless by a large excess of air.

There will, of course, be some loss due to carbon monoxide, unburned hydrocarbons, and combustible in soot in the former case, but this may be more than offset by the excessive losses caused by the heat carried away in the chimney gases in the latter. The amount of combustible in the soot and cinders deposited upon the tubes and in various parts of the setting seldom exceeds one per cent. of the calorific value of the fuel.

Radiation and Unaccounted-For Losses

These losses are determined by simple arithmetic, being the difference between the sum of the heat represented in the steam and the losses previously mentioned, subtracted from the 100 per cent. total heating value in the fuel. Consequently, unless careful attention is given to accuracy of determination of other losses the figures arrived at for this loss will be in error.

Radiation losses should not, and as a matter of fact do not, exceed 2 per cent. with well designed, well insulated boiler furnaces. On the contrary, with poorly installed settings where insulation is not properly attended to radiation losses may amount to as much as 6 to 8 per cent.

It is undoubtedly true that this loss equals a full 4 to 6 per cent. in the average plant and that it could be cut squarely in two with a comparatively small expenditure for insulating materials.

Heat Balance

The sum of all the losses and the heat absorbed by the boiler when distributed in a table or on a graph gives us the best balance. As the operating engineer, when searching out means for the elimination of losses is concerned with "coal as fired," any general representative heat balance, such as is shown in Table III. is of value for purposes of relative but not absolute comparison.

TABLE III.

Heat absorbed and losses itemized	Highest attain. efficiency Per cent.	Excellent Practice of calorific value	Good Practice	Average Practice of coal	Poor Practice as fired
Heat absorbed by boiler	89.86	80.0	75.0	65.0	60.0
Loss due to free moisture on coal	0.50	0.5	0.6	0.6	0.7
Loss due to hydrogen in coal (evaporated by H_2O)	4.20	4.2	4.3	4.3	4.4
Loss due to heat in dry flue gases	5.33	10.0	13.0	17.5	20.0
Loss due to carbon monoxide	0.00	0.2	0.3	0.5	1.0
Loss due to combustible in ash and refuse	0.00	1.5	2.4	4.5	5.5
Loss due to heating moisture in air	0.11	0.2	0.2	0.3	0.4
Loss due to unconsumed hydrogen, hydrocarbons, radiation and unaccounted for	0.00	3.4	4.2	7.3	8.0
Calorific value of coal	100%	100%	100%	100%	100%

The losses which we have been considering cover operation of the boiler at normal or high rating. In addition there are other important sources of loss in operation, such as standby losses, blow-off losses, losses due to leaky traps, valves, etc. These will all be discussed later. In our next paper we will take up in greater detail the determination and control of operating losses through the use of instruments.

Nothing is impossible to the man who can will.—Mirabeau.

RELATION OF EFFICIENCY TO BOILER ROOM CAPACITY

IN a recent paper before the American Society of Mechanical Engineers, by Victor B. Phillips, of the Cleveland Railway Co., steam boiler units were considered in relation to each of their two elements—the furnace or heat liberator, and the boiler or heat absorber, the former being the means whereby the chemical energy of coal or other fuel is transformed into sensible heat energy. The function of the furnace is chemical reaction between the combustible fuel and the oxygen of the air. As such it is governed by three factors:—1—Amount of air. 2—Degree of air mixture. 3—time. These three factors together govern the rate of combustion, the completeness of combustion and the resultant temperature of the latter; in a word, they completely determine the nature of combustion.

The boiler is a means whereby the heat liberated in the furnace is absorbed and transferred to the water. Its function is heat transmission, and it is governed by the laws expressing the several modes of heat transmission—conduction, convection and radiation. It is evident that the factors which govern combustion likewise govern very largely the heat transmission of the boiler, by the regulation of temperature and amounts of gas. Hence it follows that in the end the performance of the entire boiler unit may be expressed in terms of a number of factors over which the fireman either does or should be able to exercise proper control.

It is desirable so to define furnace furnace efficiency and boiler efficiency that their product will be the overall efficiency of the unit. To this end boiler efficiency is taken as the ratio of heat absorbed to the heat available for absorption, i.e.,

$$Eb = \frac{\text{heat in steam}}{\text{heat in steam and sensible heat in flue gas}}$$

Furnace efficiency is defined as the ratio of heat available for absorption by the boiler to the heat in the coal, i.e.,

$$Ef = \frac{\text{heat in steam and sensible heat in flue gas}}{\text{heat in coal}}$$

and

$$E \text{ (overall efficiency)} = Ef \times Eb$$

This method arbitrarily charges against the furnace all losses through the setting, such as radiation and leakage. Most of these losses do occur in the setting around the furnace, and so this arbitrary classification is reasonable. It also charges against the furnace the loss in latent heat in the vapor of the discharged flue gases.

The Furnace

The ideal furnace for any form of fuel is one in which the three factors of combustion already mentioned—amount and admixture of air, and time for completion of combustion, may be regulated independently. This furnace would have wide limits of efficient operation wherein it would be possible to attain at once both efficiency and capacity. Unfortunately the present status of the art, particularly with regard to coal burning furnaces, falls far below this ideal.

The most important methods of firing coal employ the chain grate and the underfeed and overfeed gravity stokers. In each of these cases the time of transit of coal decreases with increase of load, and is not subject to independent regulation, and also it is impossible to regulate independently the amount and admixture of air. The factors of air supply are controlled together by the amount of draft or pressure and by the condition of the fuel bed. These several inflexibilities are inherent in the present status of the art. They are serious disadvantages which may be reduced, however, by introducing in other ways a large degree of flexibility.

Since regulation of the time element by regulation of grate surface seems to be impracticable, the problem of furnace operation becomes simply the problem of the air supply, not merely over the fuel bed as a whole, but in its several parts separately. That flexibility of air supply will to some extent compensate for inflexibility in time of transit, may be illustrated by any of the underfeed gravity stokers. The grate areas of these stokers have been proportioned to give the proper time element for rated capacity.

For example, take the case of the Taylor stoker used in the equipment of the Cleveland Railway Co. plant which the writer tested. When the capacity is increased, the air supply on the lower or coking grates cannot be increased enough to burn the coal as fast as it is received from the upper grates. The result is a piling up of coke and ash on the dump and extension grates, causing not only a large loss from carbon monoxide and coke to the ash pit, but perhaps serious clinker difficulties. A variable grate surface would eliminate this trouble. It could, however, be largely mitigated by flexible and independent air control for this section of the fuel bed.

Fundamental Factors of Furnace Operation

The operating variables of the furnace

are simply the variables governing air supply. They are: (1)—Thickness of fuel bed; (2)—condition of fuel bed; and (3)—pressure drop through fuel bed. These variables may be regulated differently in different parts of the furnace, but they are in all events the fundamental factors involved. They determine efficiency and capacity. In order to operate a furnace properly, the inter-relations between efficiency and capacity and the foregoing variables must be established.

The validity of this principle has not been generally realized. Instruments for the indication of certain variables have been extensively used; yet, either the number of instruments or the amount of rational interpretation has been insufficeint. It is only in very special and limited cases that efficiency or capacity is indicated by a single variable factor such as carbon dioxide or flue temperature.

Having defined the fundamental factors of operation, it now remains to select means of indicating these quantities to the fireman. The means of indication necessarily vary for different types of stokers and furnaces. With a chain grate the thickness of fuel bed may be readily measured and adjusted, and its condition is for the most part uniform. The draft in the combustion chamber constitutes the pressure drop through the fuel bed. Thus the chain grate readily lends itself to this system, and it is a simple matter to determine by tests the relation of furnace efficiency and capacity to the operating variables. In fact, the limits of expedient and efficient operation with the chain grate are not only narrow, but readily apparent. This is a salient feature of this type of stoker. On the other hand, the forced-draft underfeed stoker is not by any means so simple, and here intelligent control is not only effective, but essential. In this case the thickness of fuel bed cannot be directly measured, nor is its uniformity so much a matter of course.

The point of primary importance is the amount of air pushed through the fuel bed and the intimacy with which it is mixed with the volatile matter forming in the lower layers of green coal and the coke of the upper layers. Roughly speaking, this intimacy increases with the resistance to air flow. It is the condition and thickness of the fuel bed that determines both the amount and admixture of air. The pressure necessary to force up a certain quantity of air is both a simple and an effective indication of the mean condition and thickness of the fuel bed; in other words, an air-pressure gauge and an air meter indicate the thickness of bed. In stokers of sufficient size to warrant the use of two air ducts, it is necessary to duplicate the air-measuring apparatus. By proper arrangement of the means of indication it now becomes possible to gauge the uniformity of the fuel bed by comparing the air indications to the two halves. Thus all the conditions governing air supply may be readily measured, and indicated to the fireman. In order, of course, that he may make proper use of these indications they must be related to the objects sought—efficiency and capacity.

The Boiler

The furnace produces heat which is available for absorption in the form of radiant energy and of hot gases—that is, the heat generated in the incandescent fuel bed is transmitted to the boiler surfaces by radiation and by convestion. It is then transmitted from the outer to the inner surfaces and to the water by conduction. The boiler employs, therefore, all three modes of heat transmission, and the variables of operation are those determining the effectiveness of each of these three modes. These variables are: (1)—Temperature; (2)—condition of surfaces; and (3)—gas velocity. Temperature is the predominant variable; it affects all three modes of transfer, in each case a temperature gradient being necessary. The condition of surfaces affects principally two modes of transmission — convection and conduction; while gas velocity affects simply convection.

It is evident that the factors governing furnace operation also determine the variables of boiler operation. The gas passing through the boiler is simply the air of combustion plus the weight of gasified coal (corrected, if necessary, for infiltration). The temperatures in the boiler are governed by the combustion conditions in the furnace. Hence, overall boiler efficiency and capacity are to be expressed simply in terms of the furnace variables—thickness of fuel bed and pressure drop through fuel bed. The function of flue temperature is simply a check upon the condition of the heating surfaces. A combined boiler-unit-operation chart brings out the essential importance of the variable factors which have been selected as determining performance. It supplies the information whereby the firemen may operate with maximum efficiency for each different load. It establishes the relation between efficiency and economy wherewith the economic policy of the boiler room may rationally be planned. Lastly, a study of such a chart and of the reasons for its characteristics becomes a sound basis for improvement in design.

EFFICIENCY IN REFRIGERATION

By M. M.

Real efficiency, about which we hear so much nowadays, consists merely in attaining a certain predetermined result by the easiest, quickest and best method. For many years aboard ship the commissary was somewhat of a secondary consideration; in fact, on some vessels the scale dropped even lower, but in any event it was never considered a serious problem. Careful investigation has, however, proved that men do better work, stick by the ship better, and are generally more useful in every respect if they are given plain, nourishing food that has been kept in first-class shape under ideal or, at least, sanitary conditions. In order to maintain such in the food compartments a refrigerating machine or, as it is most generally spoken of, an "ice machine" is essential.

To prove this to your satisfaction, it is only necessary to visit a ship immediately upon her return from an extended trip and look at the interior of the ice box. You will find on the floor racks about one-half ton of ice or less mixed up with various meats of various kinds in different stages of health—some of them comparatively healthy and some of them rather under the weather. You will also probably find a few very much dilapidated fowls that are away off color and very soggy. This is not first-class grub, and the commissary departments are beginning to realize it, so that gradually the various boats of all kinds—freighters, tankers, passenger ships, tugs, etc., are being equipped with ice machines.

When you enter the freezing compartment of a mechanically-cooled box you will find a temperature of two to ten points below freezing point, the air crisp and clear; there are no disagreeable odors, the meat and the poultry are firmly frozen, and thereby immune to deterioration for a long period. This is the theoretical side of the question. Now to come right down to earth and talk about the most important phase of the whole subject, which is the "dollar and cents" side. On one line of steamers, where a very careful record is kept of the "per meal" cost, the actual saving per meal by mechanical refrigeration with a well known system over the old style of ice method of cooling was 3½ cents.

This freighter had thirty men aboard, which at 3½ cents showed a saving of $1.05 per meal, $3.15 per day, or $1,149.75 a year. The plant on their boat cost in the neighborhood of $2,000, so that the outfit was paid for in two years. This is an actual saving when all costs of operation against cost of ice, etc., are taken into consideration. In some cases the saving might be less; in some it might very well be more. The above is cited as an instance to show that in addition to the improved sanitary conditions that are obtained by mechanical refrigeration there is an actual saving in money. Another point in favor of mechanical refrigeration is that whatever you buy in the way of supplies is fully used. Meat with a system installed in a vessel can be carried to the Orient and back in first-class shape, but a ship is lucky that can carry meat half-way across the Red Sea where ice is used as a refrigerant.

THE SCOTCH OF IT

Two old Scotsmen sat by the roadside, talking and puffing away merrily at their pipes.

'There's no muckle pleasure in smokin', Sandy," said Donald.

"Ho dae ye mak' that oot?" questioned Sandy.

"Weel," said Donald, "ye see, if ye're smokin' yer ain bacca ye're thinkin' o' the awfu' expense, an' if ye're smokin' some ither body's, yer pipe's ramm't sae tight it winna draw."—Tit-Bits.

Electricity and Hydraulics

PRINCIPLES AND OPERATION OF MODERN ELECTRICAL EQUIPMENT. VII

By A. M. PERE

THE field magnets of a generator serve to generate the magnetic flux and to properly distribute it through the armature core. Three types or varieties of windings for the field magnets of direct current machines are in common use; shunt, series and compound, the latter being a combination of the other two.

The shunt winding, as one will notice if a field magnet of this type be examined, is composed of a large number of turns of fine wire, the end terminals of the series of coils being connected to brushes of opposite polarity. In consequence the whole voltage generated by the machine is available for sending current through the field magnets. Fig. 1 shows the shunt wound dynamo connections.

Shunt wound dynamos find considerable use in storage battery charging, being the only suitable form for the purpose, and also for many other uses for large machines generating power for industrial or lighting purposes the compound wound machine is used, as will be explained later.

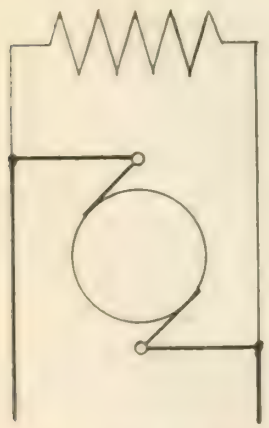

FIG. 1—DIAGRAM OF SHUNT WOUND MACHINE

As in all dynamo-electric machinery the generation of current is first started by the action of a certain amount of residual magnetism present in the field magnets, no matter how soft the iron. This generates extremely weak currents which, however small, are available for use in the shunt fields and thus strengthen the magnetism. The increased magnetism generates a greater voltage and renders available in consequence a still larger current and the voltage builds up to a value fixed by the characteristics of the machine. Fig. 2 shows the voltage characteristic curve for a shunt wound dynamo. If the field rheostat of the dynamo is not adjusted as the current supplied by the dynamo is increased the voltage falls only a little at first, but afterwards more rapidly until the point c along the curve is reached. For the dynamo considered the terminal volts are 120 at no load and only 100 when 50 amperes flow. The remaining part of the curve to d is of no practical interest beyond showing the fact that it is impossible to overload a shunt wound dynamo by short-circuiting the leads. No more current will flow on a dead short circuit than is indicated by od, in this case about 12 amperes. This is explained since the armature is short-circuited no current flows in the fields and the only current generated is that due to the residual magnetism present in the fields.

A dynamo designed so that the drop along the line a b c is slight would be nearly a constant potential machine. If the load changes gradually the voltage can be maintained at a constant value by hand manipulation of the field rheostat, the man in charge cutting out resistance and allowing more current to flow and thereby raising the voltage sufficiently.

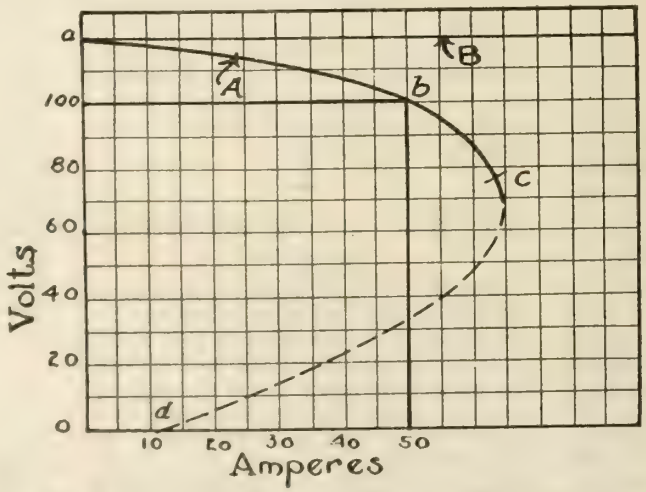

FIG. 2 CHARACTERISTIC CURVES FOR SHUNT WOUND MACHINE.

Series Generator

The series generator is arranged in an entirely different manner to the shunt wound machine. By reference to Fig. 3 it is seen that the whole current generated by the armature is used in energizing the field magnets, a comparatively few turns of heavy wire sufficing. Two machines of similar design and of the same size, one series and one shunt wound, will require the same magnetic flux in the fields under similar conditions and the ampere turns for the series wound machine would be found to be the same as those for the shunt wound to produce an equal amount of magnetism. The series wound generator cannot build up voltage unless it is connected to an external load, as there is no current flowing through the fields and any voltage generated is due to residual magnetism only. Consequently the no load voltage of the series machine is zero as compared to the shunt machine, whose voltage under similar conditions is at its greatest value.

It may be remarked that the series wound generator is very seldom met with in practice although the series motor is an extremely useful type and one used very largely where large starting torque and variable speed are required.

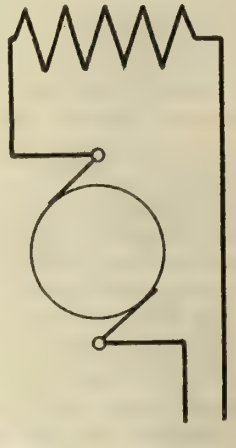

FIG. 3—DIAGRAM OF SERIES WOUND MACHINE

The Compound Wound Machine

The compound wound generator or motor is the most largely used type and it owes its popularity through the ability of the designer to control its characteristics to meet any requirement usually found in practice. The interpole type of

machine will be taken up in a later section of the course.

The compound wound dynamo or motor has both a shunt and a series field winding. As the current supplied by the generator to the external circuit increases the current through the series field increases and thus strengthens the magnetic flux and this increase in field strength automatically raises the e m f generated. If this increase is just enough to balance the drop which would be caused in a shunt wound machine the voltage will remain constant in value and would have a value represented by the line aB, Fig. 2.

The amount of this compounding effect of the series winding can be regulated so that the voltage will drop, remain stationary or rise, with increasing load. A generator in which the voltage drops is said to be under-compounded, one in which the voltage remains stationary is said to be compounded flat, and one in which the voltage rises is said to be over-compounded. An over-compounded dynamo is of use where power is to be delivered at the end of a transmission line, the extra rise in voltage automatically compensating for the line drop and keeping the terminal voltage constant. It is possible to regulate the compounding effect of a generator by means of a resistance shunted across the series field of the generator and in effect by passing a certain desired amount of the current around the series field.

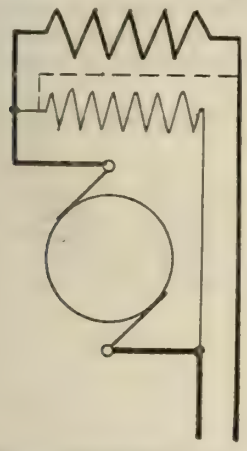

FIG. 4—DIAGRAM ILLUSTRATING CONNECTIONS FOR COMPOUND WOUND GENERATOR

Compound Wound Motor

It is readily surmised that the shunt and series windings of a machine may either assist or oppose each other, according to the way in which they are connected up. If they assist each other the machine is said to be cumulative wound and if they oppose each other the machine is said to be differential wound In the case of the cumulative compound motor the strength of the magnetic field increases with an increase of current in the series field since both fields act together and the series field counteracts the weakening of the shunt field.

It is a well known fact that a generator operates equally well as a motor and it is sometimes of use to know what changes would be necessary if it be desired to make this change. The direction in which a direct current generator will operate when it is changed to a motor may be quite easily determined.

It is well to remember that in the dynamo the armature conductors are pushed by the mechanical force applied from outside in a direction opposite to that in which they would go in a motor if the current in each case had the same direction. With this in mind, then, if the direction of the armature current and the direction of the magnetic flux through the magnetic circuit of the machine both remain unchanged, or if both are changed when the machine is changed from a generator or a motor, the direction of rotation will be reversed.

If either one of the above directions be changed and the other remain the same the direction of rotation will remain the same.

To reverse the direction of rotation of a motor either the direction of the armature current or of the magnetic flux must be changed, but not both.

If a shunt generator be changed to a motor it will run in the same direction as before, no matter which way the current enters or leaves it, for, if the polarity remains the same the direction of the shunt field will remain the same while the armature current reverses in direction, and if the polarity be changed the shunt field will be reversed, while the armature current will remain the same.

This leads to the general statement that a shunt generator when changed to a motor will operate in the same direction, regardless of the polarity of its terminals, if no change in connections has been made.

If a series generator be changed to a motor it will reverse in direction, for if the polarity is kept the same both armature and field currents will be changed and if the polarity is changed the armature and field currents will BOTH remain as they were.

The cumulative compound generator presents a slightly more difficult problem when changed over to a motor, for it will combine the characteristics of both shunt and series motors and will become a differential compound motor. Likewise if the machine is a differential compound generator it will become a cumulative compound motor. The direction of rotation of such a machine will depend upon the relative strengths of the two fields. For example a differential compound motor may start up under the influence of the series winding and after the shunt field current has had time to build up in value, the armature may stop and start to rotate in the opposite direction.

Next month's section will go into these relations more fully and will be illustrated with diagrams showing the various arrangements that are possible.

Answers to Last Month's Problems

1. Cores of armatures are built up of thin sheets or laminations to prevent the formation of eddy-currents in the iron of the armature. These eddy-currents if formed would be a source of considerable loss of power and would generate considerable heat.

2. Two general methods of winding direct current armatures are in common use, the lap winding and the wave winding.

3. Consult last month's course for the answer to this question.

4. In the lap winding as many brushes are required as there are poles to the field magnets. In the wave winding only two brushes are required.

This Month's Problems

1. What are the common methods of winding the field-magnets of direct current generators and motors?

2. What is the difference between these methods?

3. Is it possible to overload the shunt wound generator?

4. Will a shunt wound generator run as a motor without reversing ?

5. Will a series wound generator run as a motor without reversing?

NEW PROCESS OF TUNGSTEN FILAMANUFACTURE

A NEW German process for making lamp filaments of tungsten involves forming the lamp filament out of one long crystal. It is impossible, according to the "Electrician" to make tungsten crystals form gradually out of a mixture of tungsten powder and thorium oxide. The mixture is squirted through diamond dies into a filament of 0.02 m.m. to 1 m.m. diameter. This filament is then drawn through a chamber in which it is rapidly heated to a temperature of 2,400 deg. C. to 2,600 deg. C., and with a velocity of about 2.5 miles per hour, which is rather slower than the crystallization velocity of tungsten, so that a single crystal of indefinite length is formed. The chamber is filled with a neutral gas, and the heating is performed in two stages by a pair of electrically-heated coils, through the centre of which the filament is passed. The filament in this state is ready for use in a lamp without further treatment. It is softer than drawn tungsten wire at low temperatures and hard at high temperatures, which makes it particularly suitable for use in lamps. Filaments consisting of a single crystal of 25m. length have been produced in this manner.

Canadian Agents.—Jones and Glassco of Montreal have just been appointed Canadian Agents for the Lamson Co. of Boston, Mass. They are one of the largest manufacturers in the world of pneumatic tube carriers, and also manufacture gravity carriers and belt and chain conveyors.

Turbo-Alternator Rotors: Features of Mechanical Design-I.

A Review of the Conditions Underlying the Mechanical Design of the High-speed Alternator Rotor—Suggested Specifications For Guidance in Purchasing Equipment

By S. F. BARCLAY, Ph.D., B.Sc.

THE history of the development of the alternator for direct coupling to high-speed steam turbines is very similar to that connected with the evolution of other outstanding features of modern machinery. In dealing with the subject of rotor design before the Institution of Electrical Engineers, London, Eng., recently, the author pointed out that old construction had been applied to meet new conditions, and as failures developed improvements had been introduced to overcome them. The process is lengthy and wasteful, but essentially natural.

Features of Early Design

The outstanding feature of the earlier electrical machinery was the disregard of mechanical soundness. Reliance was placed on string and tape in an astonishing degree. Nothing has led to the development of electrical machinery from the mechanical point of view more than making alternators suitable for direct coupling to high-speed steam turbines. With the advent of peripheral speeds of over 4½ miles per minute the unsound construction of earlier times has disappeared, and the modern turbo-alternator rotor is not surpassed as a high-class engineering production.

The need for the use of material of the highest grade is obvious when it is recalled that at the periphery of a 31-in. diameter rotor running at 3,600 r.p.m. a mass of 1 lb. exerts a centrifugal force of 2½ tons, and in the case of a 5,000 kw. alternator at 3,000 r.p.m. the total centrifugal force at the normal running speed is about 15,000 tons. The kinetic energy of such a rotor at the normal running speed is about 7,000 foot tons—

FIG. 1

5,000 kw. 3,000 rev. per min. alternator with 31 in. diam. rotor. Curves showing the much lower bursting stress in a solid as compared with a laminated rotor of the same diameter. Stress calculated at 20 per cent. above normal speed.

equal to the muzzle energy of 23 75-mm. field guns, and sufficient to hurl 380 lb. of steel a distance of 6 miles.

It is clear that eliminating weakness of construction by the lessons of failure is not a permissible policy with such machinery. The precise nature of the duty at the various parts of the rotor must be thoroughly investigated, the material employed must be of the highest grade, and the factor of safety must have satisfactory value.

Severity of Conditions

The conditions to be faced are most severe, and the author doubts if they are sufficiently well realized by either user or maker. Even with the smaller sizes of high-speed machines that marked the progress of a few years ago mechanical failures were not unknown, and the author is of the opinion that with the machines for large outputs at from 1,500 to 3,600 r.p.m., such as are being made to-day, mechanical failures must result unless greater attention is paid to the excellence of design and of material.

It is somewhat remarkable that the specifications drawn up by consulting engineers make little attempt to ensure mechanical excellence, although the electrical performance is usually very fully stipulated. Occasionally one notices in specifications that the engineer has some uneasiness with regard to the mechanical performance and endeavors to safeguard his client's interests by specifying the tensile qualities of the rotor steel and by calling for an unusually high overspeed test, but one never sees stimulated the all-essential permissible ratio between the stress and the quality of the material in the direction of the stress.

For instance ,it is not sufficient to test the tensile qualities of the steel in an axial direction at the end of the shaft when the maximum stress is in the body of the rotor in a radial direction; nor is it logical to display concern in the quality of the material and disregard the complementary factor—intensity of stress. It will be shown later that an excessive overspeed test is on the one hand undesirable, and on the other does not necessarily establish mechanical soundness.

Comparison of the Solid and the Laminated Rotor

Even up to a few years ago the controversy as to the relative merits of the salient-pole rotor and of the cylindrical rotor still flourished, but with the advent of large outputs at high speeds the former type has now disappeared. There still remains, however, some discussion as to the advantages of the solid as compared with the laminated rotor. From the electrical point of view, for polyphase work there is no essential difference. For a given design theoretical considerations would indicate that the maximum momentary short-circuit current would be less with the laminated than with the solid rotor, for the same reason that there is a greater resistance to the flow of the rotor eddy-currents at the moment of short-circuit, on the creation

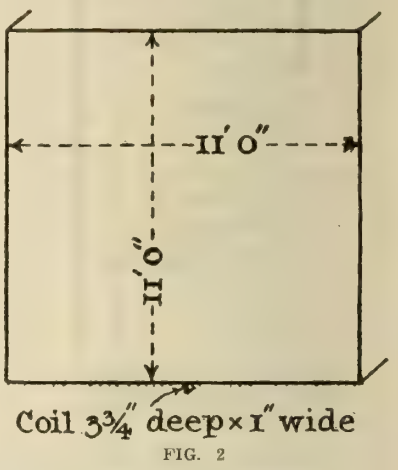

FIG. 2

of which depends the momentary loss of the stator self-induction. Since, however, the alternator with a solid rotor can quite well be designed to stand short-circuit at the terminals without damage, this property of the laminated rotor is without practical value.

On the other hand, the better electrical contact that is established between the slot wedges with the solid rotor causes the rotor to constitute a more effective damping winding and so gives greater electrical stability. With an unbalanced load there is less heating with a laminated than with a solid core, but again this quality is usually of no advantage, since by exercising certain obvious precautions the solid rotor can be employed successfully with any degree of unbalanced load that occurs in practice.

In a normal turbo-alternator the output is limited by the rotor heating, and it is obviously a great advantage of the solid rotor that the ventilating channels can be arranged to secure the best cooling effect, whereas with the laminated rotor they have to be provided where mechanical considerations permit.

Weakness of Laminated Rotor

The essential weakness of the laminated rotor is the presence of the central hole through which the shaft passes. On account of the thickness of the metal between the bottom of the slot and the

inner bore being comparable in magnitude with the diameter of the bore, the maximum stress exceeds considerably the average stress, and the design becomes

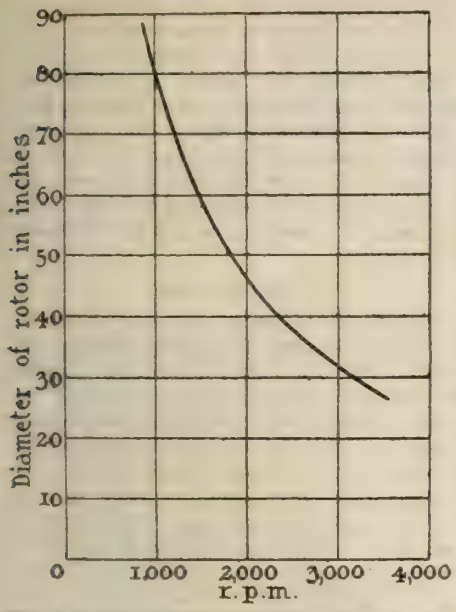

FIG. 3—RELATIONSHIP BETWEEN MAXIMUM RUNNING SPEED AND MAXIMUM DESIRABLE ROTOR DIAMETER.

limited by the stress at the inner periphery.

As an example, with a 3,500 kw. alternator at 3,000 r.p.m. the maximum stress on the inner fibres exceeds the average stress across the belt of metal by about 20 per cent. In addition to the stress caused by the centrifugal force, there is to be considered the stress due to the shrinkage fit of the stampings on the shaft. To ensure that the core shall remain tight on the shaft when running at the overspeed, the amount of the shrinkage must exceed the amount by which the core opens due to the centrifugal force.

Thus in the case being considered the shaft diameter would be about 12 inches, and at the overspeed of 3,600 r.p.m. the inner bore would increase about 0.018 inch in diameter. Making allowance for normal tolerances in workmanship, the shrinkage would need to be not less than 0.02 inch to ensure that the core shall always remain tight on the shaft. This requirement for mechanical soundness gives an appreciable increase to the stress of core discs. Just at this part of the core disc where the stress is a maximum the strength is very considerably reduced by the keyway cut into the lamination. The weakness could be avoided if instead of cutting the keyway in the disc a projecting tongue could be formed to register in a keyway in the rotor shaft. Such an arrangement is not practicable because the tongue would prevent the inner bore of the core being machined.

To give the essential good fit of the core on the shaft, the core should be bolted solidly together between stout end-plates and be bored to a smooth surface, and the shaft then be ground to suit with the necessary shrinkage allowance. Apart from being desirable to ensure a good fit, it is vitally important to bore out the core in order to remove the metal that is strained and weakened by the punch. This matter will be referred to later.

Solid Rotor Advantages

The solid rotor has the great advantage that the bursting stress is always less than the stress in the tooth and the former stress has therefore never to be considered. A comparison of the hoop stress for a laminated and a solid rotor is shown in Fig. 1 for a 3,750-kw. alternator. It will be seen that even with a much deeper tooth the maximum stress in the forged rotor is only 13,800 lb., against 34,500 lb. in the laminations.

Another matter to receive consideration when discussing the laminated rotor is the question of the material available for the core discs. Such material is prepared by rolling down hot slabs into sheets of the thickness required. The structure of the steel is influenced very considerably by the finishing temperature of rolling and by the rate of cooling. With a large, thin sheet it is impracticable to maintain a uniform temperature throughout, and a micro-examination after rolling shows appreciable variations in the crystalline structure at different parts of the sheet.

Careful annealing by the re-crystallization that results does much to remove such variations, but no matter what care the manufacturer may exercise, some variations in the finished sheet are unavoidable, and particularly so when thorough annealing is not permissible on account of the lowering of the tensile strength. Moreover, the fibre is determined by the direction of rolling; the effect of the final passes predominates, although the earlier passes have a slight permanent effect. Even at a given part of a given sheet the ductility is found to vary somewhat according to the direction chosen, although the tensile strength may be fairly uniform. Minute local imperfections that would be without effect on a fairly thick plate may appreciably weaken a thin plate.

Since material of this kind is inherently less dependable than a high-class forging, the factor of safety should be higher than with the solid rotor, but due to the weakening effect of the central hole the designer has to be content with a lower factor of safety.

Manufacturing Features

To meet the demands of the electrical engineer for steel sheets having a high tensile strength, some manufacturers have taken advantage of the additional strength given by cold working. An interesting theory of the hardening of metals by cold working has been put forward by Professor Beilby. By making the final passes through the rolls at a low temperature the tensile strength is considerably increased. The action is to deform the crystals and to produce amorphous material on the surfaces of the gliding planes, resulting in appreciable hardening. Up to a certain point the more the steel is reduced in area the more the strength is increased in this way, but beyond that point the steel is rapidly weakened.

The effect of annealing such material is to remove largely the effects of the cold working, by the re-crystallization of the amorphous material that results. The elongation may be brought to a low value according to the extent of cold working—even to less than 1 per cent. Under a tensile test such material breaks abruptly without any appreciable stretching. With the steel sheets that are prepared in this way for rotors, the cold working is not carried so far, and there is usually an elongation of about 5 per cent. with a yield point of about 35 tons per square inch and a breaking strength about 40 tons per square inch.

The effect of the cold working with large thin sheets is essentially somewhat uncertain, and such material cannot be regarded as being of a high grade. There is always the chance of the process being carried too far locally and of minute internal flaws being caused. Another danger of material worked in this way and only partly annealed is the possibility of there being what is known as "rectangular brittleness." This remarkable phenomenon is more usually encountered with pure iron and very mild steel, but the author has had experience of it occurring in some degree with steel of the kind in question.

A Heat-Treating Feature

It has been discovered that if steel is worked at a temperature below 500° C., and is then annealed at a temperature below the critical point, it is liable to become coarsely crystalline. It was shown by an interesting experiment by Professor Sauveur, and independently by Mr. H. S. Kipling, that in addition to the critical temperature there is also a critical range of deformation, and if the steel is worked either more or less the phenomenon does not occur. Dr. Stead found that the property he designated "rectangular brittleness" is due to the material crystallizing with the cleavages

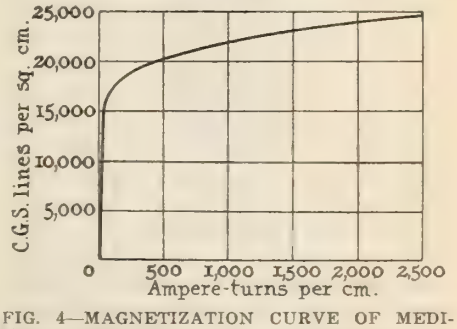

FIG. 4—MAGNETIZATION CURVE OF MEDIUM CARBON STEEL (OIL HARDENED) FOR TURBO-ALTERNATOR ROTORS.

at an angle of 45° to the direction of rolling and at 90° to the surface of the sheet. It is obvious that if the crystals are all similarly oriented the sheet would be readily fractured if the stress were

applied at right angles to any of the three cleavages, although it remains tough in directions at 45° to the cleavage planes. Annealing at a temperature above the critical point would remove this weakness, but it would at the same time largely remove the effect of the cold working and very considerably lower the tensile strength.

Reference has already been made to the weakening effect of punching metal sheets. If a micro-section of the sheet is

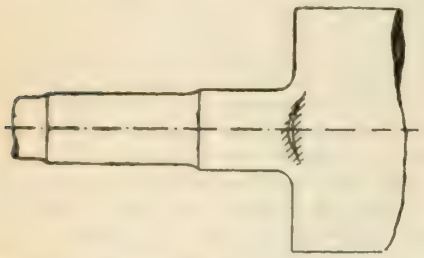

FIG. 5—FORGING DEFECT IN HIGH-SPEED ROTOR.

made it is clearly seen that the effect of punching the metal or, in a slightly less degree, of cutting it with shears is to distort and harden the crystals. Metal that was quite ductile before punching is found to be brittle round the punched edge. It is most important, therefore, that the core should be assembled in a jig and be bored out, since otherwise there would be brittleness and weakness at the part subjected to the greatest intensity of stress.

In place of cold working another method of producing plates of high tensile strength is to employ a high carbon content. The ductility of such steel, however, is not good, and it cannot be regarded as being suitable for the duty. An entirely satisfactory high-tensile plate could be produced using nickel-chrome steel, but a rotor constructed with such plates would be more expensive than a solid forged carbon steel rotor, and would be less satisfactory mechanically and electrically.

Critical Speed

Another point to receive consideration with the laminated rotor is the question of the critical speed. Practically always, the running speed is above the first critical speed, and with large outputs at 3,000 r.p.m. the running speed may be above the second critical speed. If the laminations were fairly loose in the axial direction the critical speed of the shaft could be accurately determined, but for mechanical soundness it is desirable to assemble the laminations under heavy end pressure. Additional stiffness may be given to the shaft, the deflection being reduced and the critical speed raised.

The stiffening effect is usually not permanent; under the combined action of vibration, stress and pressure, the minute undulations in the laminations are removed, and in the course of time the end pressure which might have been initially 200 tons is found to have disappeared. In the case of a typical 3,750-kw. alternator at 3,000 r.p.m., with a shaft diameter of 12 inches, a core diameter of 27 inches, a core length of 50 inches, and a distance between bearing centres of 134 inches, the first critical speed with the laminations absolutely solid would be about 2,000 r.p.m. and with the laminations free would be only about 1,400 r.p.m.

It will be seen that with a newly constructed rotor the critical speed may have a satisfactory value, but after some running there may be a lowering of the critical speed and some vibration may result. The author has had experience of several cases of slight incurable vibration with laminated rotors that has developed after prolonged running, but in only one case was the vibration so bad that the rotor had to be reconstructed.

When high-grade forgings are available the solid forging is undoubtedly preferable for all sizes of rotors for polyphase work. For small outputs the laminated rotor can be made satisfactory, but to employ the construction for large outputs is to take unnecessary risks. It is the author's opinion that for outputs in excess of 3,000 kw. at 3,000 r.p.m. the laminated construction should be employed only when it is impossible to obtain suitable forgings.

Thick Plate Construction

For large-diameter rotors at medium speeds thick plates are sometimes employed instead of laminations. This construction is preferable to using thin sheets, but the weakness of the centre hole and the high hoop stress, together with the unsuitability of using rolled plate with a pronounced fibre subjected to high stress in all directions, are still present, and when the critical speed is below the running speed trouble with it is equally if not more pronounced.

Another alternative is the construction of using plates of considerable thickness held together with through bolts with a short shaft length at either end and no central hole. The great weakness of this construction is the difficulty of making the bolts satisfactory. The deflection is due almost entirely to the elongation of the bolts, the area of the plates being large compared with the area of the bolts and the compression of the plates therefore negligible. A very slight elongation of the bolts takes all compression off the plates, and consequently at the underside of the rotor the plates are out of contact. Each time the rotor turns round, stress in addition to the initial stress is thrown on the bolts. In the case of a 1,500-r.p.m. rotor this intermittent superimposed stress is applied and removed over two million times a day.

It is claimed for the construction that the variation of stress can be maintained at so low a value that in spite of the rapid variation the duty is within the capacity of the steel. It is to be remembered, however, that the calculated stress may be considerably exceeded. In the first instance, it is difficult to know exactly the initial stress, which is usually determined either by measuring the pull on the spanner tightening the nuts or by measuring the elongation of the bolts. Again, the action of tightening the nuts may impose a very considerable torsional stress. Also, the driving torque imposes a longitudinal as well as a shear stress on the bolts. Above all, a bolt cannot be regarded as being dependable for carrying a rapidly fluctuating stress.

A Case in Point

The design usually calls for the bolts to be a reamered fit in the plates, and there is thus a sudden reduction of area at the parts where the thread is cut. The added elongation when the additional load is thrown on the bolts by the action of the rotor turning round is not uniformly distributed over the whole length, but is concentrated to an extent dependent on the reduction of area at the short length between the end of the fitting part and the face of the nut. In the course of time this concentration of elongation in company with the weakening effect of cutting the threads tends to cause failure by fatigue close to the nut. With one case that came to the author's notice of a 6,000-kw. 1,500-r.p.m. alternator constructed in this way, it was found that after 2½ years' running some of the plates at the centre of the core had moved slightly out of centre. On dismantling the rotor it was found that the opening and closing of the plates at each revolution, as described above, had caused fretting of the spigots and between the bolts and the reamered holes, and where initially there had been a good fit there was found to be a clearance on the spigot and in the bolt holes of 1-50 inch.

Another disadvantage of the plate construction is apparent when the critical speed is considered. Since the bolt area in tension is small compared with the rotor weight, the deflection in the body of the core is considerable and hence the critical speed is very low. It is almost impossible to avoid some degree of synchronism of the normal speed with the harmonics of the natural period of

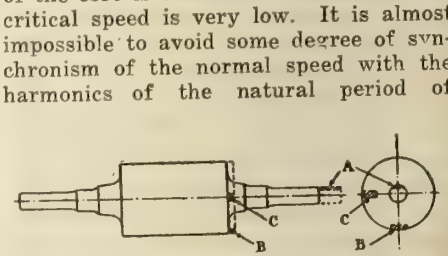

FIG. 6—TESTS FROM AN OIL HARDENED CARBON-STEEL ROTOR.

transverse vibration. The effect of the plates meeting, by the great area of compression they offer, prevents any appreciable swing of the rotor beyond the neutral axis. Vibration is thus damped, and such rotor has no real critical speed, but there may be sufficient vibration to be appreciable.

Such a construction can be seriously

considered only with relatively large and relatively low-speed rotors, and is only to be employed when forgings are unobtainable.

Maximum Diameter of Forged Rotor

The forged rotor having no central hole is very much stronger in its resistance to bursting than is the laminated rotor as shown in Fig. 1. It can be shown mathematically that a minutely small hole through the centre of a rotating cylinder doubles the stress. In addition to the gain due to the omission of the hole, there is the greater area of steel to carry the load. The capacity of the added area to carry load is considerably greater than the extra load due to the centrifugal force of the added metal, and so altogether the bursting stress is so low that it has not to be considered.

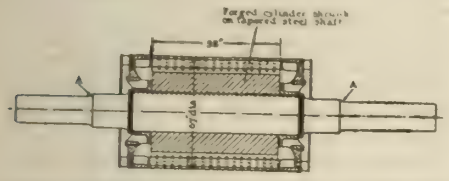

FIG. 7—ROTOR FOR A LARGE 1,000-REV. PER MIN. TURBO-ALTERNATOR.

The maximum stress with the solid forged rotor is always in the tooth, but the stress never reaches a high value, the maximum rotor diameter being determined by other considerations.

With the type of winding now in universal use, of concentric coils of flat copper strip, there is a fairly clearly defined limit to the rotor diameter that may be employed for a given speed. There are to be considered the stability of the end windings exterior to the core, the pressure on the insulation between turns, and the retention of the end windings against the action of centrifugal force. In the case of a 5,000-kw. alternator at 3,000 r.p.m. with a 31-in. diameter rotor, when running at the overspeed of 20 per cent. above normal the average value of the maximum pressure on the insulation is about 5,000 lb. per square inch. The desiderata of the insulation between turns are good electrical properties, capacity to stand high temperatures without deterioration, and mechanical strength. The author is very strongly of the opinion that pure, hard mica is the only material that is really suitable for the purpose. Asbestos sheet is sometimes employed, but it cannot be regarded as being a suitable material. The electrical properties of the asbestos may perhaps be made sufficiently good by careful impregnation, and it is, of course, very suitable for resisting heat, but mechanically it is not good. The space available for the rotor copper determines the rotor output and hence the alternator output, and it is obvious that the thickness of the insulation between turns must be reduced to a safe minimum. A thickness of 0.01 inch cannot be exceeded without unduly adding to the size of the machine for a given output. However carefully asbestos may be made, with such a thickness it is not possible to avoid weak spots. The copper is never absolutely flat, and any high point is very liable to crush the asbestos locally and cause short-circuiting between turns. Pure, hard mica is very good mechanically and does not yield locally in this way.

Illustrating Centrifugal Force

Fig. 2 shows a cross-section through one of the rotor coils of such an alternator, and there is drawn to scale on top of it a block of steel equal in weight to the centrifugal force exerted by the coil. When it is considered that the length of each outer coil exterior to the core is about 4 feet, it will be appreciated that the difficulty of preventing any side slipping of the coils, however well they may be supported, may become a limiting factor of speed. The illustration does not exactly reproduce the running conditions, since the centrifugal force is not uniform throughout the coil as is the pressure due to the weight, but varies from zero at the bottom to a maximum at the top. The sketch nevertheless serves to convey a much better idea of the duty than a mere statement of figures can do.

As a structure such a coil is not well adapted to carry a great load without distortion—particularly having regard to the high-frequency vibration that must be present in some degree, however perfect the balance. Moreover, the tendency to move due to expansion which may not take place uniformly with all the turns at either end of the core, and to the low coefficient of friction between the polished surfaces of the copper and the mica, adds to the difficulties.

The stability of the coils is much improved as the breadth of the strip is increased. The practice of most makers seems to be to employ rather a large number of coils with a relatively narrow section of copper—six or seven coils per pole being common. A far better arrangement is to use fewer coils of greater copper breadth. Also, reducing the ratio of wound slots to slot pitches is not only better mechanically, but is more effective electrically, as shown by Dr. S. P. Smith. The limitation in this direction apart from electrical considerations is the section of strip that can be handled conveniently.

Under steady compression between flat surfaces mica can stand great loading before failing. In service, however, it is to be remembered that the conditions are not nearly so ideal. There is always some degree of high-frequency vibration present and the surface of the copper is never quite flat. For these reasons a big margin of safety is necessary.

Whereas the limitations due to end-coil stability and insulation pressure are indefinite, as will be seen later the limitation due to the difficulty of retaining the rotor end-windings is quite definite. Having regard to these circumstances, the author believes that for a normal speed of 3,000 r.p.m. a 32-in. diameter rotor will come to be regarded, if not as the maximum permissible size, at least as the maximum desirable size. The peripheral speed of such a rotor is 25,120 feet per minute.

For a given peripheral speed the centrifugal force of a given mass is inversely proportional to the radius. With the larger diameters, however, it will be found that with an increase of diameter there is roughly a corresponding increase in the weight of the various parts, and for speeds below 3,000 r.p.m. the desirable peripheral speed is actually reduced somewhat as the diameter is increased. In Fig. 3 is shown the relationship between the angular speed and the maximum desirable rotor diameter.

Choice of Rotor Steel

The obvious requirements of the rotor steel are that the permeability should be as high as possible and that mechanically the material should be suitable for the duty. The exciting energy required to drive the flux through the rotor varies considerably according to the relative proportions of the design and the performance of the machine. In an average case, however, it may be of the order of 15 to 20 per cent. of the full-load excitation. It is important, therefore, that the permeability should be as high as possible consistent with satisfying the mechanical requirements. As already mentioned, the maximum stress in the rotor is not great, and the designer has apparently a wide choice of steels. The choice, however, becomes rapidly narrowed down when it is stipulated that in addition to having the necessary strength the steel must have capacity to withstand shock and fatigue, be tough,

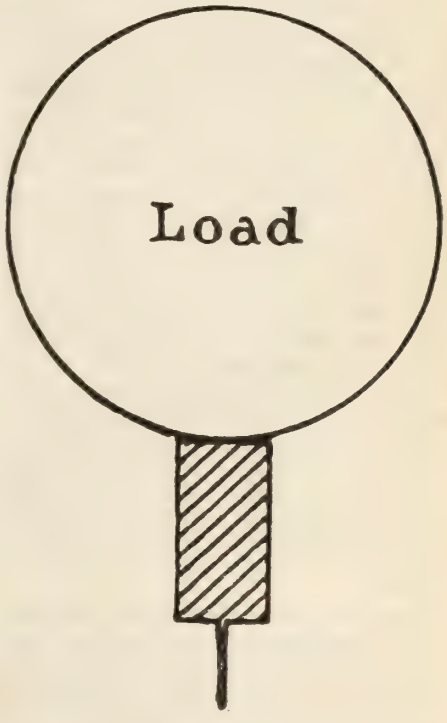

FIG. 8—SHOWING HOW A BEAM CAN BE WEAKENED BY ADDING TO ITS SECTION.

ductile, of the kind that is least likely to have flaws, the best suited to use for a large forging, and above all be dependable in the highest degree. Beyond doubt, the steel that best fills these requirements is an oil-treated carbon steel. Such a steel, containing about 0.38 per cent. carbon, after oil treatment has an ultimate strength of 38 tons per square inch, a yield point of 22 tons, an elongation of 22 per cent. on 2 inches, and a contraction of area of 40 per cent. It is of the class of steel that is used for such purposes as railway axles, and has to resist shock and fatigue and be dependable above everything, and is therefore admirably suitable for alternator rotors. The permeability of this steel is quite good, as shown in Fig. 4.

Yield Point and Elastic Limit

It is usual to express the factor of safety in terms of the ultimate strength —which is not quite logical, since it is the yield of the material that marks the

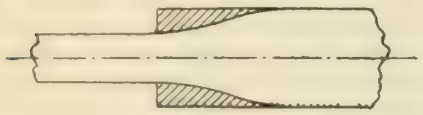

FIG. 9

A sudden increase in diameter may be regarded as adding metal to a gradual increase and is analogous to the adding of a thin rib to a beam as shown in Fig. 8.

limit of safety and not the actual fracture. The ratio between the yield point and the ultimate strength differs considerably with different classes of steel, and varies a little even with any particular steel according to the nature of the heat treatment. For example, with a mild carbon steel in the annealed state the yield point may be about 50 per cent. of the ultimate strength, and after oil hardening may be increased to 60 per cent. With a high-tensile nickel-chrome steel the ratio may be as high as 85 per cent., and with cold-drawn steel wire as high as 95 per cent. For this reason the author is of the opinion that the factor of safety should always be expressed in terms of the yield point. It would be better still to express it in terms of the elastic limit, but the difficulty is that the elastic limit cannot be determined in a tensile test and can really only be found by a long series of tests under reversals of stress.

The yield point is defined as being the stress at which there is a complete yield of the material that is observable to the eye. The true elastic limit is reached at some lower stress when incipient but not measurable permanent set is caused. In stipulating the factor of safety the nature of the duty has to be considered, and the value that would be safe for a steady load would be quite unsafe for a rapidly fluctuating load. As we have seen, the maximum stress in the solid forged rotor is in the teeth. The stress is unidirectional and constant, and a factor of safety of 2 to 1 on the yield point is to be regarded as satisfactory with dependable steel. With this factor of safety the maximum permissible tooth stress with the quality of steel suggested is 11 tons per square inch. With a well-proportioned rotor having a diameter of 31 inches—which, as explained, is approaching the largest diameter that it is desirable to employ for a normal speed of 3,000 r.p.m. with the type of rotor now being made—the maximum tooth stress at 20 per cent. overspeed is about 9½ tons per square inch. It will be seen, therefore, that the quality of steel suggested well meets the requirements.

It might be thought that, if a higher stress could be allowed, a narrower tooth could be provided and there would be more room for rotor copper and consequently a greater output. The question of the tooth density, however, has to be considered. There must be some saturation in an alternator to give it magnetic stability. There are cases on record of alternators that would not operate satisfactorily due to insufficient saturation, the excitation being overwhelmed by the armature reaction at changes of load.

With a turbo-alternator the necessary saturation must be provided in the rotor teeth—that being the only part of the machine where a high density can be arranged or is permissible. On the other hand, if the saturation is carried too far, the loss in the teeth becomes excessive. With a normal 5,000-kw. alternator at 3,000 r.p.m. the exciting energy required for the rotor teeth is of the order of 10 per cent. of the full-load excitation. With a badly-proportioned rotor the loss may be as high as 20 per cent.

In general, it will be found that with a stress of about 10 tons per square inch the corresponding tooth density is as high as it is desirable to employ, and the oil-hardened carbon steel therefore satisfies the electrical as well as the mechanical requirements.

Use of Alloy Steel

It is sometimes suggested to employ an alloy steel for the rotor, but there is very little gain, if any, in doing so with the objects immediately in view, and on the other hand there are pronounced disadvantages. For instance, if an alloy steel were employed with the object of being able to use a smaller tooth to give increased winding space, it would be found in most cases that the increased magnetization loss due, not only to the higher tooth density, but also to the lower permeability would more than offset the gain due to the increased copper space.

There is the objection to using an alloy steel that for a large rotor forging it is inherently not so reliable, there being a greater probability of internal flaws being present. A hole should always be bored through the forging when an alloy steel is used, and the bore should be carefully examined to see that there are no internal flaws. As already explained, the effect of the hole is more than to double the hoops stress. so that the body of such a rotor actually would be weaker than if a carbon steel were used.

An interesting case came to the author's notice a few years ago of a rotor forging breaking just where the shaft merges into the body of the core. The steel used was 3½ per cent. nickel having a yield point of 29 tons and an ultimate strength of 46.5 tons per square inch, and an elongation on 2 inches of 22 per cent. It was found that a huge internal cavity had been caused by the operation of forging, as shown in Fig. 5. The corresponding part at the other end of the rotor was cut open, and although there was no cavity the steel was in a highly stressed and weakened condition. Insufficient care in forging might cause weakness in this way with any steel, but it is much more probable with an alloy steel than with a carbon steel.

In another case that came to the author's notice a high carbon steel was employed having the composition of 0.61 carbon, 0.59 manganese, and 0.23 silicon, and the tensile properties of ultimate strength 49 tons per square inch, yield point 22 tons to the square inch, elongation on 2 inches 18 per cent., and reduction of area 32 per cent. After being in service for 3½ years the forging failed with a fatigue flaw in the neck of the journal. A micro-examination showed that the steel had not been properly heat treated and had a large grain size. Such a steel, and more particularly in the absence of correct heat treatment is not at all suitable for a high-speed rotor.

The use of improper steels of this kind, and bad mechanical design—with which not even a good steel could stand—have led to a number of failures that have given rise to the feeling amongst those not familiar with the conditions that the solid forged rotor is less reliable than the built-up design. For the onerous conditions of high-speed work, it is not good enough to use a block of any kind of steel in any state of heat treatment and to machine it without regard to fundamental mechanical requirements.

There is no doubt that provided the right kind of steel is used, correctly forged and correctly heat treated, and that the mechanical design is sound, the solid forged rotor is by far the best construction, and the author has never heard of a single failure when these conditions have been observed. The only justification for the built-up construction is for small rotors and when high-grade forgings are not obtainable, and for single-phase work.

The forging for the turbo-alternator with its radial stress presented a new condition to the steel maker and, not because there was any real difficulty with it but because it was a new requirement that they had not investigated, some makers would not undertake the work.

With ordinary care in forging there is no difficulty in giving the required radial test. The tensile strength radially is very much the same as in the longitudinal direction, but the elongation is usually lower. Three tests should be made from each forging—one from the shaft end, one tangentially from the core, and one radially from the core, as shown in

Fig. 6. With an oil-hardened carbon steel containing about 0.38 carbon the results shown in the table in Fig. 6 may be expected. The figures given are actual results; the makers' guarantees with regard to elongation, and particularly in the radial direction, would be somewhat lower.

Limit of Forging Size

There are limits to the size of forging that a steel manufacturer can undertake. There is the inherent limitation due to the rate of cooling of the interior of a large mass of metal. The size of the crystals and hence the properties of the steel are profoundly influenced by the rate at which it cools. If the mass of steel were unduly great, the cooling of the interior would be so slow that the mechanical quality in consequence could not be made to conform to the necessary requirement. With the forgings for turbo-alternators of the sizes so far considered the problem does not arise, and the limitations are the manufacturer's facilities for casting an ingot sufficiently large and the capacity of his forging plant.

Nothing definite, therefore, can be laid down as to the largest size of rotor that can be produced in a single piece, but it is in the neighborhood of 50-in. diameter. That is to say, for all outputs so far contemplated at 3,600, 3,000, and 2,400 r.p.m. a single forging can be obtained, and also for all except very large outputs at 1,800 and 1,500 r.p.m. For very large outputs at 1,800 r.p.m. and lower speeds a single forging may not be satisfactory. In such cases the soundest construction is to forge a hollow cylinder with a shaft extension attached to each end, or better still carried on a through shaft as shown in Fig. 7.

Forging the cylinder on a mandril does work on the steel and gives it its best qualities on the inner periphery where the hoop stress is a maximum. Moreover, in quenching, the oil has access to the bore and the maximum benefits of the heat treatment are conferred at the part of maximum hoop stress. With such large rotors there is no difficulty in so proportioning the belt of metal between the bottom of the slots and the bore that the hoop stress is kept down to a satisfactory value. For very large rotors this construction therefore constitutes an excellent arrangement.

Shaft Design

In determining the design of the shaft it is most important that the proportions should be such that the curve of deflection is smooth and free from any sudden change. The forces due to the rotor weight cause the steel to yield elastically until the reacting force balances the weight. So long as the duty on the individual crystal is within its capacity the structure is safe, but if that limit is passed the crystal deforms by slip taking place along the cleavage planes. The excessive burden falls on to the neighboring crystals, and they in turn fail, and so on until fracture is caused. For the structure to be safe, therefore, not only must the area of the steel be adequate for the load to be carried but the proportions must be such that it is free to yield elastically to exert its reactive force without any local over-stress being caused.

If the design is such that there is a tendency for some part of relatively small area to resist the general deflection, that part may be overstressed and failure may result. An example of such a case is given in Fig. 8. The beam with the fin projection and the load can be so proportioned that before the beam has deflected sufficiently to give the necessary reaction to support the load the crystals at the bottom of the rib are overstressed. Failure, therefore, would result with such a construction, whereas the beam without the fin would carry the same load satisfactorily.

Where there is an abrupt increase of diameter in a shaft the conditions are somewhat but not exactly similar. Just where the increase of diameter takes place the shaft portion is under stress and is yielding elastically. The flow of stress into the larger diameter is somewhat gradual, and the face of the metal that is rising at right angles from the smaller diameter to the larger diameter carries little or no stress, and there is therefore in intimate contact steel that is elongating and compressing elastically and steel without stress, and great weakness is thus caused. A gradual change of diameter represents a normal design, and a sudden change is to be regarded as adding metal to the normal design as shown shaded in Fig. 9. The added metal tends to prevent the normal elastic deformation and has inadequate strength for the purpose. In such a case the tendency to fail is often increased by the crystals at the junction of the two diameters being torn and weakned by the action of the cutting tool.

In Fig. 21 is shown a case of failure that came to the author's notice a few years ago. It will be noticed that there is a very sudden increase of diameter between the bearing journal and the large oil baffle that is formed solid with the shaft. After 11 months' running the shaft broke in the position shown. Not only was the design thus most unsound, but the material was unsuitable, being of a high-carbon steel that had not been heat treated and having a very coarse grain size.

Abrupt changes in the curve of deflection must therefore be carefully avoided. The shaft should be gradually stepped to avoid any sudden increase of diameter, and wherever a change of section occurs a carefully formed radius should be provided. Gauges to check the accuracy of the radii in important places, such as in the neck of the journals, should form part of every shop inspector's equipment.

In addition to being carefully formed, the radii should be given a fine finish and good polish. It has been shown by Professor Beilby that the effect of polishing is that the superficial molecules become mobile and form a thin viscous layer with surface tension analogous to that of liquids. After a very short period the layer loses its mobility and solidifies into a vitreous amorphous state, forming a very strong cementing material. On the other hand, if the surface is left rough the surface crystals are torn and weakened, and the conditions are favorable for fatigue to develop.

The need for avoiding abrupt change of section applies to all parts of the rotor, and at the junction between the teeth and the body of the rotor ample radii should be provided.

Alternating Stress

The maximum reverse stress in the rotor is in the neck of the bearing journal at the part marked "A" in Fig 7. The weight of the rotor puts the figure at the top of the shaft into compression and at the bottom of the shaft into tension. As the shaft turns round the stress changes from tension to compression. In the case of a 3,000-r.p.m. alternator the number of reversals per day is 4,320,000; that is to say, the number of reversals daily is equal to what investigators into the subject of alternating stres have regarded as a complete endurance test.

Failure from fatigue is really the same as failure under a simple tensile test in so far as it is the result of the overstressed crystals yielding plastically by slip along the cleavage planes. The essential difference is that failure by fatigue is relatively very slow and is localized, not being accompanied by any general yield of the material.

The investigations of recent years have thrown some light on the reason for steel failing under an alternating stress that could have been carried indefinitely if applied constantly. Ewing, Humphrey, and Stanton have discovered that the failure generally starts in the ferrite grains which consist of iron in its crys-

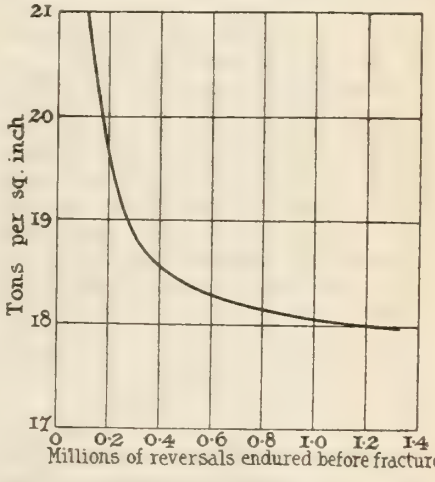

FIG. 10—ENDURANCE TESTS OF OIL HARDENED CARBON STEEL WITH 2,000 ALTERATIONS OF STRESS PER MIN.

talline and therefore softest state. The stability of the ferrite is much less than that of the aggregate, so that stress insufficient to permanently strain the aggregate would be more than sufficient to break down the ferrite grains if the stress had access to them. Professor Beilby discovered by studying the vibrations of cold-drawn reed before and after annealing that although the crystalline

phase is more elastic than the amorphous phase, yet the amplitude of vibration is greater in the latter state. It is reasonable to expect, therefore, that when an aggregate composed of two phases is subjected to rapidly alternating stress, the harder element with its greater amplitude will cause the softer element with its less amplitude to cary an undue proportion of the stress.

Under a simple tensile test, as the load is increased the first crystals to fail are those that are the worst circumstanced with regard to size and the orientation of the gliding planes. These crystals deform plastically, and the stress is therefore to a certain extent removed and becomes more distributed over the aggregate. Such a point marks the true elastic limit, and the stress has to be increased appreciably before there is the general deformation of the crystals as a whole that is observable to the eye, known as the yield point.

That a steel crystal has strength after permanent deformation is explained by Professor Beilby to be due to minute particles being torn away from the contact surfaces, of a lower order of magnitude than any crystal unit, that form an amorphous cement stronger than the crystals themselves. The action is analogous to what happens when the surface of metal is polished as explained above. With any normal metal it is found that fracture always takes place along the cleavage planes of the crystals themselves, and not by the failure of the amorphous cementing material that holds them together. The presence of this amorphous material produced by the rubbing along the gliding planes may quite well, therefore, have the effect of making the crystal stronger after yielding than it was before. This explanation agrees with the fact that under a tensile test a greater stress is required to rupture the material than was necessary to cause the yield.

The conditions necessary for failure by fatigue are that the real elastic limit of the steel is exceeded but that the yield point is not reached. If the elastic limit were not reached, the metal, would not fail however many reversals may be made; and if, on the other hand, the yield point were reached the failure would take place by ductile elongation before fatigue developed. After the first local yielding of the worst circumstanced crystals, if the load is kept constant nothing further happens and the steel would carry the load indefinitely.

If, however, the stress is quickly reversed, the slip of the crystals will be reversed, the movement being considered to be facilitated by the newly produced amorphous material being in a temporarily mobile state. At each reversal there is corresponding slip along the gliding planes, and more of the amorphous materials is produced until the crystal is exhausted and failure results. This process then begins in other crystals and spreads until complete failure is caused.

Reverse Stresses

It was thought by some of the earlier investigators into the subject of reverse stress that the liability to fail increased with the speed of reversal. It is now generally agreed that these investigators were misled by the peculiarities of the type of testing machine they employed. It is fairly certain that failure by fatigue is independent of the speed of the reversals unless the speed be very low or very high. It is well known that after plastic deformation if steel is allowed to rest the strength increases. This quality, however, is without value in shafts since the period of rest required is a matter of days unless hastened by the action of heat. On the other hand, if the speed is very high the time that the load is applied may be insufficient for yield of the material to take place. The time required for a crystal to deform is appreciable whatever stress may be applied, and it is to be expected that if the stress is applied for a very brief period only there may be insufficient time for the steel to deform plastically, although the magnitude of the stress may be sufficient to cause rupture if applied steadily. Dr. B. Hopkinson has shown that steel wire having a yield point of 17.8 tons per square inch and an ultimate strength of 28.5 tons per square inch can carry a load of 33½ tons if it is applied for about only 1-1,000th part of a second. He has also shown that with reversals at the rate of 7,000 per minute the resistance of metals to reversals of stress is appreciably greater than at low speeds. The speed at which this property becomes of value has not been clearly determined. Dr. Stanton states that with tests he made at speeds of from 100 to 2,200 reversals per minute there was no evidence that the rate of reversal had any effect on the resistance to failure. It is probable that at the normal running speed of the high-speed alternator the alternations of stress have a maximum effect, since the speed is not sufficiently high for it to have any ameliorating effect, and on the other hand the great speed tends to bring unforeseen load into play. It becomes necessary, therefore, to give very careful attention to the design in this respect.

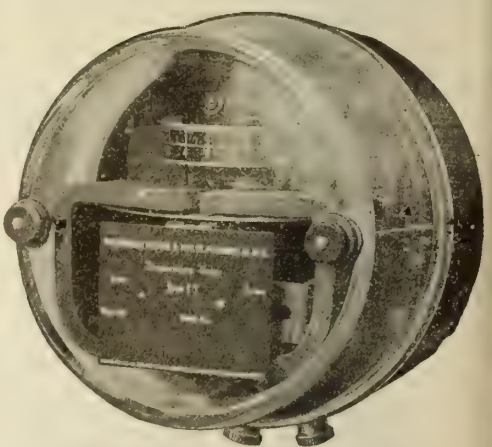
When making tests under alternating stress the procedure is to apply a load that it is known will produce failure and note the number of alternations before breakdown results. The test is repeated with a similar specimen under a reduced load, and so on until the load is found under which the specimen will not break however many alternations may be made. If the results are plotted the curve is parabolic as shown in Fig 10, the horizontal asymptote showing the stress with which an indefinite number of reversals would not produce fracture.

The fatigue failure is so insidious in its action and so many unforeseen factors may be present to contribute to it that a big margin of safety is desirable. For instance, the calculated stress may be much exceeded by a slight error of alignment, and the possibility of minute irregularities or flaws must be considered, which for any other condition of loading would be without practical effect. Moreover, the torsional stress which is a contributing factor may have its normal value much exceeded by a short-circuit. Further, in expressing the factor of safety in terms of the yield point it is to be remembered that the true elastic limit, which, as explained, determines fatigue failure, is considerably lower than the yield point. It has been shown by Ewing and Humphrey by observing the creation of slip bands under alternations of stress that the true elastic limit of a carbon steel may be only 52 per cent. of the yield point. Taking all these factors into consideration, it is the author's opinion that the combined calculated stress in the neck of the journal should not exceed 7½ per cent. of the yield point of the steel. With the high bearing duties of to-day—journal speeds of 6,500 feet per minute being quite satisfactory—there is no difficulty in keeping within the factor of safety.

(To be continued)

MAKING TEMPERATURE TRIP THE CIRCUIT-BREAKER

The oldest form of overload protection is electromagnetic, cutting off the current if it reaches a value deemed dangerous. The fact that most electrical apparatus can withstand momentary overloads without danger has gradually led operators to push up the current values at which electromagnetic protective devices will operate, or to dispense with them entirely, rather than undergo the inconvenience of having them disconnect the machinery on momentary peaks.



WESTINGHOUSE TYPE CT RELAY

A method of visual protection on the basis of temperature was the next step. Exploring coils were built into the apparatus and used to indicate the temperature of hot spots by means of electrical instruments.

The latest step is a relay, the type CT, built by the Westinghouse Electric and Manufacturing Company, which automatically trips the circuit-breaker when the temperature reaches the danger point under excessive current. It may be used to protect any alternating-current apparatus from excessive heating if the apparatus is so arranged that exploring coils can be installed.

The relay is intended to protect ap-

paratus against overheating from sustained overloads. To afford this protection with the least interruption of service the breaker should be tripped through the direct effect of the temperature of the apparatus. The relay should be so arranged that it prevents the breaker from tripping if the overload is of such short duration that the temperature does not rise to a dangerous value; while, if the overload persists the breaker must be tripped out as soon as the temperature rises beyond the critical value. This is accomplished in the type CT relay as follows:

The type CT temperature relay operates on the Wheatstone bridge principle. Two arms of the bridge are copper exploring coils arranged to be placed in the oil or embedded in the windings of the apparatus to be protected, the other two arms are unchanging resistance mounted in the relay. The current for the bridge is supplied by the current transformer connected in the circuit of the apparatus to be protected. The relay has two windings, corresponding to and co-operating to produce torque in a manner similar to the current and voltage coils of a wattmeter. The main winding is a coil operated directly by the current transformer. The auxiliary coils are connected to the Wheatstone bridge arms similarly to a galvanometer connection, and thus receive current, the magnitude and direction of which depends upon the resistance of the search coils. Above a certain temperature the torque of the relay is in the contact direction and below, in the opposite direction. It will thus be noted that in order to close the contact, two predetermined conditions must co-exist: excess current and excess temperature. Neither one will separately trip the relay.

The type CT relay is similar in construction to the Westinghouse Type Co. except that it has special windings and two additional terminals.

The construction of the exploring coils will vary, depending on the kind of apparatus with which they are to be used.

A WORKING HYGROMETER

HYGROMETERS are used in factories for ascertaining the amount of water vapor in the air by means of a moving part in two forms—one employing a wet and a dry bulb thermometer, in which a fine thread of mercury is forced along a glass tube by reason of the expansion of a small amount of mercury in a bulb. The other type owes its movement to the alteration of length of one or more hairs under the influence of a change in the moisture in the surrounding air. The movement of the hair actuates a small pointer moving along an index, and in the case of the thermometer the mercury moves parallel to the index. In each case the force represented by the movement is exceedingly small and the instruments as used in textile factories serve as a guide for the adjustment by hand of the humidifiers that furnish the additional atmospheric moisture that is required for the treatment of cotton in dry weather.

It has for many years been known that cotton is most easily spun or woven when it contains about 8½ per cent. of moisture; with less it is liable to be brittle and to have an increased loss in waste. The amount of moisture the fibre contains depends on the state of the air surrounding it, and as the dampness of the air is constantly changing, the cotton when exposed is constantly varying in weight. Along with this change of weight is a variation in thickness of each fibre, and this variation, when the fibre is spun or woven, results in a change of length in the fabric, although the loose fibre does not alter in length, nor does any vegetable fibre appear to do so.

As soon as moistening or humidifying appliances began to be used and the variation of atmosphere dampness from hour to hour during the working day was observed the need of an automatic regulator became evident, for no manual adjustment of water supply to the spraying apparatus could keep pace with the natural changes in the air. As a makeshift, the factory windows were closed and humidity was obtained at the cost of ventilation. The gain was, however, only a partial one, for excessive humidity produced lassitude among the operatives, resulting in bad work and irregular attendance.

Many inventions have been tried to obtain automatic adjustment of the moistening apparatus which used water at a pressure of about 100 pounds per square inch, but the resistance of the valves and stuffing boxes offered serious difficulties when attempts were made to control them by a movement due to the influence of moisture on organic fibrous material. A rope may be made to lift a hundredweight suspended on it by soaking it with moisture, but the operation would take so much time as to be of no use as a humidity regulator, and if it depended for moisture on the air it might take hours to show results. Promptitude is an essential in this case, for by carefully made experiments it has been found that loose cotton fibre is influenced in less than one minute by a change of moisture in the air around it.

The many failures of regulators controlling high pressure water supplies suggested a new departure, dealing with low pressure water which was atomized mechanically for air moistening. This invention was the subject of a recent patent obtained by Mr. John Wallace, of Bombay. The experimental regulator was a band of closely woven light canvas, 70 feet long, suspended by the edge beneath a roof and exposed to the influence of atmospheric change. The canvas was free of size and one was fixed, while the other was kept in tension by weight equal to four pounds per foot in width. The free end of the canvas was connected with a recording cylinder, on which a line was drawn that showed the movement of the canvas during every hour of the twenty-four. During a period of two years that the canvas remained in tension it showed no sign of fatigue, and it proved that a piece of canvas seventy feet long and three feet wide would indicate every change of atmospheric moisture in the air by a movement of 9-16 inch for each per cent. of moisture absorbed by the cotton while kept in tension by a weight of 12 pounds. The prompt sensitiveness of the canvas was due to its very large surface. Twelve pounds weight raised 9-16 of an inch thus represents the result of the absorption of 1 per cent. of its weight in moisture by the canvas band, and a test of the resistance to movement of a balance valve passing water full bore through a 1-inch pipe at one foot of pressure was 40 grammes, or about 1½ ounces.

This experiment points to the possibility of controlling automatically the supply of moisture in the air of a cotton mill, the regulator being of cotton. The canvas band has a certain length due to a content of 8½ per cent. of moisture within its fibres, and any increase or diminution of this moisture alters the length. Having a very large surface, absorption and evaporation take place very quickly, and with each change the movement acting on a balanced valve may control the water supply flowing to the vaporizers.

This device is applicable to public buildings, palaces and hospitals where electric current or other motive power is available.

WESTERN CANADA AND ALBERTA COAL

Still Figuring On How West Is To Be Kept From the Shivers This Winter

The Westerners are having their own times just now. They are speaking in terms of heat units and B. T. U. and every other kind of heat measurement even unto calculating steam with a yard stick. They have to burn Alberta coal, and they want to know how much more fuel they will need than in the days when they consumed anthracite. The university of Edmonton compares them like this in regard to the B. T. U. value:—

Edmonton coals	8,900 to 9,200
Pennsylvania	12,800 to 14,800

The Calgary "Canadian" does not believe that the Manitoba field has been inched for Alberta coal. That paper says:

It would be far from actual facts to say that the Manitoba market has opened to Alberta coal. Possibly it can be described as "cracked." It is taken as vastly encouraging that Manitoba is in reality keenly interested in the opportunity of the Alberta coal supply. Once the prairie consumers find that Alberta coal keeps perfectly in reasonable storage; that it can always be secured when wanted, and that it cuts to a skeleton the customary corpulent coal bill from Pennsylvania; then the seams of Alberta can expect to be

made to produce night and day, winter and summer.

Need Summer Market

It's the summer market that counts after all. The big mines are crowded to the limit during the four or five winter months. The equipment must be kept up to practically a year-round capacity for this rush interval. Then comes spring and the orders disappear in a night. The demand is gone and the miners disperse.

This is the condition in the coal situation that the producers have been fighting against for years. Not until last winter when Canada had its first experience with the closing of industries and schools, and the enforcement of "heatless" days, has the argument of the Alberta coal companies gone home. It is not so hard at the present time for Manitoba, for example, to appreciate the fact that a few tons of coal, brought from Alberta at a low price during the summer and stored away in a shed or basement, can save a deal of worry, shivering and expense, when snow begins to swirl and railways lose themselves in traffic.

If this same fact could be sown on the eastward prairies and let mature the problem of all-year-round production at Alberta mines would be finally solved, and all Canada could well rejoice in the solution.

THE COST IN COAL OF AVOIDABLE BELT SLIP

ONE of the very simplest transmission losses to overcome is belt ship, and since belts are used to so great an extent it is worth while looking into the matter with considerable thoroughness. To show the extent of the loss of money through slipping of the main belt alone a chart, supplied through the courtesy of the Cling-Surface Company, Buffalo, N.Y., is shown herewith, upon which this is easily ascertained. By glancing up and down column "D" of this chart it is evident that the "cost of avoidable belt slip per year in dollars" may vary all the way from the smallest sums into the thousands of dollars.

Where the power in the first place is generated by a steam engine and is then transmitted to a generator or to the main shaft through a main belt it is evident that the "entire coal pile" passes through that in the form of energy, literally speaking.

If the belt slips, which it should not do, a certain portion of the coal pile does not "get through," but is lost into the atmosphere in the form of waste heat. A main belt is merely a "link" connecting the engine with the generator or with the machines themselves. In fact, every belt that transmits power is a connecting link and the efficiency of that link depends largely upon the freedom from slippage and the avoidance of strain on the shafts. Slipless, easy-running belts are most desirable.

If the power plant is considered as a chain of links, the first link is the coal on the grates, which only perfect combustion can turn into maximum heat; next the boiler shell and tubes—they must be clean to bring the heat link to the steam link; next the steam line from boiler to engine or turbine, large enough and well insulated; then the engine or turbine link which joins heat energy and mechanical energy—only careful design, proper valve setting and much care minimize losses here. Then, where power is distributed solely through belts and pulleys, the belts, pulleys, and shafts or electrical cables to the final motors and belts are the connecting links up to the machines themselves.

If the efficiency of every link is maintained at its highest point the power end of the plant is beyond criticism. The overall efficiency will then be very high. But if the efficiency of every link is low or indifferent the overall efficiency of the power end will be distressingly low.

Each per cent. of slip in a main drive represents a loss of 1 per cent. of the coal pile, and roughly 2 per cent. of the potential power in the driving pulley of the engine is represented by belt creep. Its loss is unavoidable because of the elasticity of the belt. This has been recognized and provided for in the chart, so the reader can proceed to connect known values, while the intersection with column "D" gives the avoidable money loss.

Simply zig-zag across the chart twice with a straight edge, as shown by the dotted lines, and the money loss is immediately found. Thus, if the total belt slip is 6 per cent. (column "A") and the cost of coal per ton is $4 (column "B") run a straight line through those two points and locate the intersection with column "C." Then from that point of intersection run over to the tons of coal burned per year (which in this instance has been stated as 1,000 tons) and the cost of ovaidable belt slip per year is shown by column "D" as being $160.

To give a clear idea as to the meaning of "total belt slip per cent." take an example. It is found by means of a revolution counter that a given driven pulley is rotating only 940 times per minute, while calculations show that without slip it should rotate 1,000 times per minute; 60 revolutions per minute, therefore, are absolutely lost. Dividing this 60 by the r.m.p., that pulley should make you get 0.060 or 6 per cent., which is the "total belt slip." After having made this determination, now it is a simple matter to apply it to the chart, as has been done and determine the money loss per year due to such slip.

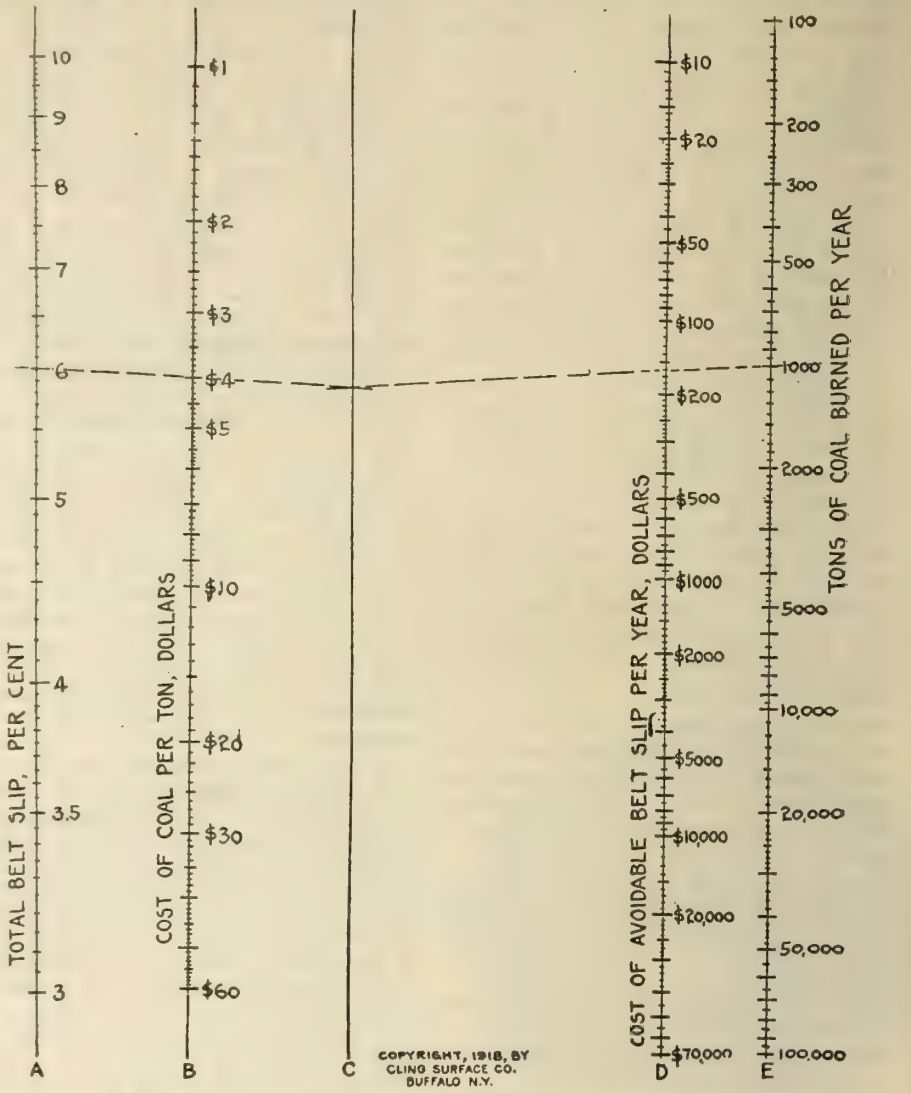


CHART SHOWING HOW AVOIDABLE BELT SLIP INFLUENCES COAL COST.

THE DETERIORATION OF STEEL PLATES SUBJECTED TO THE ACTION OF ALKALINE LIQUORS

THE present phenomenal expansion of various chemical industries has brought to the fore numerous questions relating to the design and durability of various types of apparatus connected therewith. One of the most interesting subjects recently investigated has been the action of caustic liquors upon the steel plate of which autoclaves and other apparatus are made. Anything bearing on this subject is of value to those connected with the design and operation of steam generating equipment as in many cases it is necessary to use boiler feed water having a comparatively large alkaline content.

Recent Experimental Work

Mr. C. E. Stromeyer, chief engineer of the Manchester Steam Users' Association, has recently conducted a series of tests to determine the effect of alkaline liquors upon iron and steel, as regards the promotion of brittleness and the difference in behaviour when various stresses, strength of liquor and periods of exposure are compared. His conclusions are summarized in a memorandum recently issued, from which the following is abstracted:

One recent experience with the action of caustic soda was with some evaporator tubes. These cracked above and below the tube plate. At the plate zone, where the expander had produced a compression stress in the tube there were no cracks, but tube plates in which there would be tension stresses, and also occasional rivets were very seriously affected. In order to ascertain whether, as suspected, the embrittlement of steel in contact with caustic liquor occurs only when the steel is in tension, the following experiment was carried out:

Several pairs of rings, as shown in Fig. 1, were cut out of a solid plate. Some of these rings had taper outer

FIG. 1

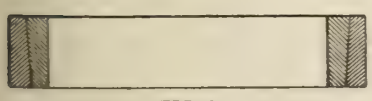

FIG. 2

edges, others had taper inner edges. They were placed one above the other as shown in Fig. 1, and the one ring was driven over the other as shown in Fig. 2. By this means the outer ring would be maintained in a condition of tension, and the inner one in compression. There were altogether seven rings. One ring was not stressed, but boiled for a short time, one pair was annealed before stressing, the other two pairs were not annealed. The one annealed, the other unannealed, but stressed rings were placed in a caustic evaporator in which the density was not excessively high, and these were returned to this office after four months' exposure. All the rings were then cut up into small segments, and of each ring one short piece was bent inwards, and the other outwards.

The results were very consistent. All the untreated samples, and also all those which were in a compressed condition when exposed to the caustic bent double without the least sign of cracking, but the two, the annealed and unannealed rings which were in tension while exposed to the caustic, cracked in innumerable places when bent. These cracks appeared both on the outer surface, which was in direct contact with the caustic, and on the inner surface which was not in contact with caustic but was pressing hard against the compressed inner ring. Evidently, therefore, the influence of the caustic had penetrated through ¼ in. of metal.

Further Experiments

In view of repeated inquiries, and also because of a very alarming experience it was decided to deal with the question on more comprehensive lines. Accordingly four sets of bars were obtained, viz., open-hearth steel both acid and basic, Bessemer steel and wrought iron. They were cut into 10-in. lengths, curved in boiler rollers, placed back to back between two stout iron plates (see

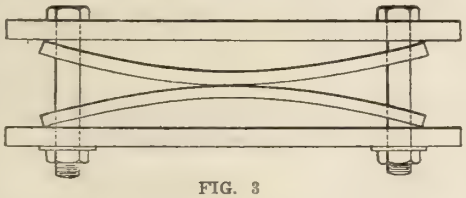

FIG. 3

Fig. 3), and the end screws were then screwed down, whereby the samples were nearly flattened as shown in Fig. 4. In the meantime four autoclaves were produced, one set of four samples was inserted in each one of these, caustic soda solutions of various strengths were poured into the several autoclaves, which were then hermetically sealed and placed in the steam space of a Babcock and Wilcox boiler and left there for four months.

On removing and opening the autoclaves it was disappointing to find that the treatment had entirely removed the spring out of the samples, the least turn of the bolt nut allowing it to be slacked back entirely. The condition of maintaining the samples in a stressed condition had, therefore, not been fulfilled, and on testing the samples by bending them, it was found that their ductility had not been impaired in the least. This experience was very disconcerting and may account for the results obtained by Professors Heyn and Parr, who could detect no effect due to straining. The experience is, however, not without practical interest, as it points to a possibility that caustic liquor may cause a slacking back of rivets and caulked edges, and lead to leakages. The experience also reminded us that during the previous tests it had been noticed that the two rings, Fig. 2, which had not been exposed in the evaporator were firmly wedged together, while the exposed ones dropped apart quite easily. Evidently nearly all of the spring had gone out of the metal.

Hardening Effect of Alkalies

The caustic liquor had, however, produced a very marked effect on the samples, Fig. 4. The samples as bent and exposed were too wide for the impact testing machine and had to be sawn in two. Much to our surprise the bandrun at the very slowest speed, and even

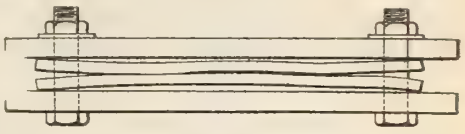

FIG. 4

then broke their teeth, and yet the original bars could be cut quite easily at the highest speed.

It will be no easy matter to devise tests which will maintain the samples in a strained condition, for in the above experiments the stress had to be produced by the elasticity of the material, and if that fails the stress disappears. The case is different in a boiler, for there the stress is due to boiler pressure, and though the caustic may relieve some stresses, as is shown by the flying off of rivet heads, the average stresses will be maintained and some local stresses may be even increased.

Professor Heyn has published nothing on this subject but wrote that he could not confirm my results. Professor Parr in the 94th bulletin of the University of Illinois deals with the following points. He notes a change of electric potential if steel is immersed in caustic. The tensile tests show a reduction of tenacity of about 30 per cent. after treatment, but this reduction was not influenced by changes in density of the liquor. The elongation improved about 10 per cent. The samples which were stressed during exposure behaved in the same way.

Judging by our experiments and the description of Professor Parr's it is doubtful whether his samples were really stressed while exposed. He also submitted some of his exposed samples to alternate (fatigue) stresses, and found a reduction of about 20 per cent. in the number of reversals before fracture occurred. The impact test results were about 10 per cent. lower for the treated than for the untreated specimens.

The Influence of Hydrogen

Professor Parr's most important results are his determination of the hydrogen which is absorbed by steel and iron when immersed in caustic soda, and as it is well known that hydrogen makes certain steels very brittle these determinations should explain the brittleness. However, as already stated, this brittleness seems to be produced only if the steel is stressed during exposure.

The seriousness of the action of caustic soda will be evident from the following case:—

At the works of one of our members, complaints were made to the manager that steam was escaping from one of the

boiler shells to such an extent as to damage the goods in a drying loft above the boiler house. A boiler maker was sent for who found some headless rivets in the butt strap of the third shell ring, and he was able to knock off a few more rivet heads. He renewed altogether nine successive rivets (in the outer or lowest row) and reported to the manager that he had noticed cracks in the shell plate between the butt straps. He suggested inserting additional rivets! Fortunately the works' manager took a more serious view of the situation and informed us. Our inspector removed a few more rivets and found more cracks, whereupon we asked that the butt straps should be removed, which was done.

Nature of the Cracks

The nature of the series of cracks was then revealed (see Fig. 5). Close to the rivet holes the cracks gaped as much as ¼ in., and the region between two rivet holes seemed to be completely disintegrated, so much so that a few pieces could be picked out. The surprising point about this case is that although the length of the crack was 5 ft. 6 in. (the boiler was built of four single-plated strakes 7 ft. 6 in. long, yet the friction of the butt straps prevented the plate from slipping out. The shell plates were 25-32 in. thick, the butt straps ¾ in. thick, the rivet holes ⅞ in. diameter, and the pitches 2½ in. lengthways and 2⅝ in., 2 in., 2⅝ in., 2 in., and 2⅝ in. circumferentially.

The cause of the cracking of the plate could not be investigated for the following reason. I had been empowered to buy the whole or part of the boiler, but difficulties were constantly raised by the owner, and as time was passing I offered to send a man to the works who would cut out the fractured plate. Instead of assisting in the discovery of the cause the owner induced the builders of the boiler to buy it back. When we heard of this we at once applied to them for some portion of the plate, but after some delay we were informed that they were quite satisfied in their own minds as to the cause of the failure, and that they had in the meantime sold the boiler to a second-hand dealer. After some delay we received his name and at once applied to him, but the answer was equally unsatisfactory. The only piece of information which was obtained from the boiler-makers was the name of the steel maker. These works have a well-established reputation, but seeing that our inspector had most carefully searched the plates without finding any brand, although the plates measured nearly 8 ft. by 25 ft., and as these boiler-makers had on previous occasions been using Continental basic steel, I do not attach much importance to this information.

Nevertheless, although the boiler-maker may have had reasons for objecting to a searching inquiry, it does not follow that the quality of the material was the only or the primary cause of the failure, which failure may have been due to the treatment which the boiler had received while in use. Until our suspicions were directed to the quality of the steel our impression had all along been that the crack was due to the introduction of caustic soda into the boiler which admittedly had been the case, for the condensed steam from some caustic evaporators at these works was drained into the hot well and was said to be very alkaline upon several occasions. As the make-up water was fairly pure and the boilers were steamed for long periods at a time, the water in the boiler might easily become concentrated to a dangerous degree.

Effect on Marine Boilers

This view receives some confirmation from a paper by Dr. Wolff of Holland, which was read at a recent meeting of the Iron and Steel Institute. His company (ship owners) seems to have had quite a crop of shell-plate failures. First one marine boiler exploded, this is almost a unique experience, then the shell plates of a sister ship boiler were found to be cracked in a very similar manner to that of the present boiler, and then other boilers failed, but about these no details were given, though it was mentioned that some were built of acid steel.

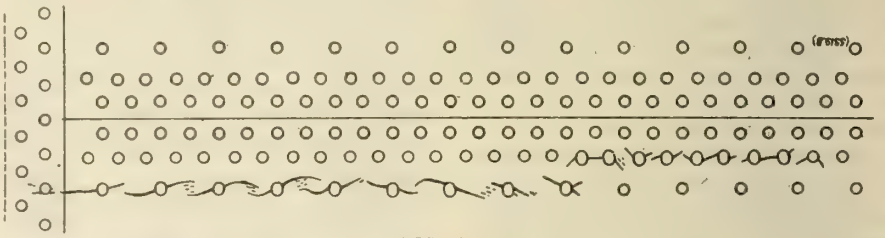

FIG. 5

RELATIVE FATIGUE TEST RESULTS EXPRESSED IN PER CENT. OF AN UNTREATED SAMPLE.

Duration of Immersion. Days.	Temperatures during Immersion. 100 Deg. C	180 Deg. C	280 Deg. C
	%	%	%
5	..	..	79
8	..	..	56
10	..	64	57
13	..	..	**80**
15	..	69, 82	75, 73, 79
16	..	..	77
17	85	..	..
19	..	82	..
23	..	88	..
24	..	90	..
30	110	..	..

Dr. Wolff seems to attribute these failures to the well-known irregular distribution of stresses in riveted joints, which are common, of course, to all marine boilers, of which there are probably 50,000 afloat and perfectly safe, but at the end of his paper he makes a very significant remark, based on Professor Mercia's experiments, and published in Professor Parr's paper (see above), which seem to suggest that the boilers in question had been dosed with soda for some considerable length of time. Professor Parr's paper contains the results of a number of experiments from which the information contained in Table III has been extracted. Samples of steel were immersed in solutions of caustic soda. One set was kept at a temperature of 100 deg. C. (212 deg. F.), another at 180 deg. C. (356 deg. F.), and a third at 280 deg. C. (536 deg. F.). Occasionally samples were withdrawn and tested and the results compared with those of untreated samples. These results were all reduced to percentages of the original. The tenacity, elongation, etc., do not seem to have been affected, but, as will be seen from Table III, caustic soda seems to have had a marked effect on the fatigue properties of these samples, unless, as may well have happened, the standard untreated sample had by some accident appeared better than it really was. This is quite possible for on the fifteenth day two samples were tested, and the results differed by 13 per cent.

It is doubtful whether Dr. Wolff is justified in drawing the conclusion that caustic soda causes at first a deterioration as regards fatigue and then an improvement, nor is he justified in judging the behaviour of boiler plates, which are subjected to static stresses by fatigue test experiments. However, he says, "that as the boilers crack after having been in service for one or more years, recovery of the material from the effect of alkali, mentioned by the author, should have taken place long before the cracks started."

We have therefore his case and ours in which there is a strong suspicion, though no actual proof, that caustic soda in boilers leads to dangerous embrittlement of the plates. Carbonate of soda, as is well known, is gradually converted into caustic soda under high pressure boiler conditions. This change was, in fact, the cause of a number of boiler explosions in America which led to the committee being appointed, on whose work Professor Parr based his report. But American boilers are built of basic steel which will occasionally crack even if not exposed to caustic soda, and the question still remains unsettled as to what was the cause of these several failures; was it the use of basic steel, or was it due to caustic soda?

A DEAD SHOT

The valor and candid simplicity of our Indian Babu are proverbial. A story goes of one, anent the German East campaign, who was about the most laconic, competent, deadly earnest station-master and marksman combined that ever lived. A regiment of men like him would end the war, for this is the wire he sent: "One hundred Germans attacking station. Send immediately one rifle and one hundred rounds of ammunition."—Tit-Bits.

Everyone has some important work that calls him. Get at it to-day.—T. A. Clark.

Blessed is the man who has found his work—and then—gets busy!—Backbone.

Power Users Should Look Right Ahead Now

Ontario is Using and Calling For More Power Than is Available —The Steam Plant Should be Utilized For Power Where Steam is Necessary For Heating Purposes—Time to Take the Warning

By F. W. SUTHERLAND, Assoc. Editor Power House.

RECENT reports concerning the available coal supply granted the Ontario district by the U.S. Fuel Administration point very strongly to the necessity for economy in coal consumption during the coming winter. It is extremely probable that only about 70 per cent. of last winter's supply will be available.

This will probably work greatly to the disadvantage of the manufacturer employed on the so-called non-essential industries and very little relief can be expected from Hydro-electric developments until the new year when the new penstock and turbines will be available at the Ontario Power Company's plant for the furnishing of about 50,000 additional horse-power.

The extent to which the consumption of electricity has increased may be judged from the demands made upon the Niagara system of the Hydro-Electric Power Commission. The Toronto system in November, 1917, had over 50,000 customers and a connected load of about 75,000 horse-power for which at that time only about 50,000 horse-power was available. The result of this power scarcity last winter was seen in the curtailment of street and store-lighting and in the cutting off of feeders serving a purely residential load at times during the day when the peak load came on.

It is idle to expect any improvement in this condition during the coming winter, at least until new supplies of power are made available and in the distribution of the available power, munition plants, in the wider application of the term, must necessarily come first. Undoubtedly much power and light are absolutely wasted and the time is probably close at hand when drastic measures must be taken to curtail the use of electric energy now employed on luxuries and thus make it available for necessary purposes.

Niagara and the Munitions Industries

The diverse and extensive demands upon manufacturers for materials of war and of the necessity for ample supplies of power consequent upon this demand are sometimes overlooked. Of the immense amount of power generated in the Niagara district the greater part is used in manufacturing of munitions of war such as abrasives, aluminum, chemicals, steel and other electro-chemical and metallurgical products. The Niagara district supplies the bulk of the ferro-alloys, all-essential in the steel industry. Abrasives, cyanides, aluminum, carbon, electrodes, and many other products are urgently needed in the war game.

The average individual has little or no idea of the important part played by abrasives, to use the term in its widest sense. If asked concerning his knowledge of the subject, he would undoubtedly reply that it extended to the sharpening of the various cutting instruments with which he was familiar and that he possessed a vague idea that sometimes "grinding wheels were used in machine shops for various kinds of rough work."

So far is this from the truth that it need only be mentioned that modern grinding methods alone make possible the standardization and quantity production of munitions by means of the close limits in workmanship made available by their use. Not only are abrasives necessary in the making of munitions but their use is all-essential in the manufacture of machine tools, textile machinery and other means whereby everything the soldier uses and wears is made. It is interesting to note that the artificial manufacture of corundum being carried on in the Niagara district has a direct and important bearing on the production of ferro-alloys, ferro-silicon being produced in quantities as a necessary part of the process.

1. One means whereby the power shortage may be somewhat minimized is by the use of steam power wherever available. This recommendation may seem somewhat futile in the face of the scarcity of coal but much can be done in the efficient utilization of the available supply. It is a notorious fact that central station energy can often be sold for a lower figure than that for which power can be generated in the isolated fact. This in a large measure is due solely to the inefficient operation of the smaller plant and when steam is used for heating or industrial processes it is not only cheaper to generate power from it and to use the exhaust steam, but it is a serious waste of the country's resources not to take advantage of this source of power. While the most efficient prime mover is only able to extract a small percentage of the total heat put into the working fluid, steam, when this power can be generated at a cost consisting of capital charges and maintainance only and the remaining heat utilized for industrial heating and other uses, the steam engine or turbine becomes a good investment and a direct aid to conservation.

Aside from the above means of deriving energy the more efficient operation of every steam plant or other means of using fuel for industrial uses or heating is a matter of some concern. The average power or industrial heating plant is after all no more economical than that notorious fuel consumer, the house furnace, and better operation ought to be rigorously enforced. It is an easy and not very costly thing to provide indicators, gas analysis apparatus and other means of testing fuel consumption and the benefits derived from their use more than balance the outlay involved. The elimination of soot and scale on boiler surfaces and proper methods of firing are also steps in the right direction.

2. The curtailment of power used for street and ornamental lighting has been of much benefit and the continuation of this means of saving energy may be expected for some time to come. It is probable that in addition further restrictions will be enforced tending to the limitation of power used in industries not essential to the winning of the war. This if put into effect would have a twofold advantage in that it would also divert a certain amount of labor into very desirable channels.

3. The more efficient utilization of the capacity of existing plants in the Niagara district has been gone into rather carefully and much is being done along this line. Water is being used up to the limit fixed by international treaty and the excess capacity of the plants is thus being utilized. The new Chippawa project which the Hydro-Electric Commission has started will, with the more efficient utilization of the water, due to the greater head, provide about 200,000 horse-power, but this will not be available for about two to three years. The size of the individual units (50,000 horse-power) is larger than in any other hydraulic development in the world. While this plant is under construction the commission are moving as rapidly as possible to have additional equipment installed so as to have available in about ten months an additional 50,000 horse-power from the plant of the Ontario Power Company.

The situation as at present existing must necessarily work to the disadvantage of the places somewhat remote from the source at which power is generated and the recent action of the National Abrasives Company in moving to the Falls is explained when the engineering requirements in connection with the transmission losses in this case amounting to possibly 10 per cent. are obviated and an equal amount of power saved for other essential industries.

Instruction as an Aid in Power Plant Operation

WHEN the railroads were forced to adopt the air brake they were quick to see the advantages of thorough instruction in the care and maintenance of the system. Models of all the necessary apparatus used to make up the complete braking system were installed in cars under the charge of competent instructors. The sectional models showed all the parts that ordinarily would be concealed from view and the men were able to learn the functions and names of the various parts with very little trouble and much more thoroughly than would have been the case if left to themselves. It is unnecessary to comment on the many manuals and books of instruction issued on the same system and the advantages of the instruction offered are well demonstrated in the remarkably high efficiency obtained to-day.

Modern power plant equipment has been brought to a high state of efficiency in the past few years and while many improvements may yet be effected, these will probably be along the lines of more efficient plant management and operation.

Since the inherent efficiency of the equipment cannot easily be increased, a writer in *Industrial Management* goes on to say that attention must be turned to methods of increasing operating efficiency and as operating depends almost entirely upon the skill and experience of the operator an effort should be made to increase his knowledge of the machinery he is operating. Systemization and standardization of operating methods will also be in order.

It seems a poor policy for a company that is spending thousands of dollars annually instructing the public in the mechanism of electrically operated machines that it sells to install machinery costing thousands of dollars in its power plant, without so much as furnishing the men who are to operate the new equipment with the manufacturer's catalogs and instruction bulletins. Yet this is being done daily.

Probably the greatest fault in the methods of instruction that are being used by a few companies to aid the operating men is that the courses are prepared by men who are not thoroughly familiar with what the practical man needs to help him most in his everyday work. This is the cause of a great deal of energy being wasted by the instructor and instructed. The universal method or system of instruction consists of a series of lectures or talks given by college professors or technically trained engineers who are wasting time lecturing on the theory of power plant economics to men who in a great many instances are not familiar with the apparatus which they are operating. This educational work is usually too broad and advanced to apply to the problems which the practical man must solve daily.

Costly breakdowns and serious interruptions of service would many times be prevented if the operator thoroughly understood all the constructional details of the machinery in his care. The instruction and aid that the practical man needs most to enable him to increase the operating efficiency of the modern power plant is that which will acquaint him with the constructional details and the best methods of operating the machinery in the particular plant in which he is working.

The system which in practice will benefit the employee and the employer the most will be one that will familiarize the operator with the working theory of the machine, the correct names, positions, actions, relations and adjustments of all the various parts, the proper method of dismantling and assembling the machine when making inspections or repairs, proper operating methods, most likely causes and remedies of troubles that may arise while the machine is in operation, and finally the running of tests by the men on the job.

Oshawa Reformer.—There is one regretable feature in the situation, that is that many who have been making the highest wages they ever made in their lives have been living up to every cent of it and were they out of work for a few weeks, or even a few days, they would be bankrupt, and a charge on the town, as was the case through the slump of 1913. They never seem to learn the importance of preparing for a "rainy day."

Association and Personal

Word was received last week of the death in action on August 28th of Harold C. Fogarty, formerly associate editor of CANADIAN MACHINERY. Enlisting July 2nd, 1915, going overseas as a member of the 198th Battalion the following spring, he was reported wounded last year and was in hospital for some time. He was a keen student and his training as a machinist and draftsman made him peculiarly fitted for editorial work. During his work on this paper he made a wide circle of friends who will learn with sincere regret of his death.

Albert E. Gilverson, president of Rice Lewis & Son, Limited, has received word that his youngest son, Pte. Russell Lloyd Gilverson, was wounded on Monday, September 2. Pte. Gilverson enlisted in the fall of 1915, and has been of late attached to "J" Battery, 1st Canadian Machine Gun Battalion. He was educated at Woodstock College, was an enthusiast in athletics and a lover of the gun, being an accurate shot and one of the youngest and most active members of the Mimico Gun Club. On leaving college Pte. Gilverson entered the service of his father's company and occupied an important position in the sporting goods department and was well known and very popular in sporting circles in Toronto.

Tillsonburg, Ont.—An electric motor and pumps may be added to the present equipment of the waterworks pumping plant. The matter is now before the Town Council.

Power Shortage.—At a meeting of the members of the Board of Trade and Industrial Committee and manufacturers of the city last evening the recent further ten per cent. cut in the city's supply of Hydro-electric power was discussed. A resolution was adopted that a strong protest should be lodged with the Dominion Controller, Sir Henry Drayton.

Newcastle, N. B.—An electric light plant at an estimated cost of $125,000 may be erected here. The contemplated project is having the consideration of the Light and Water Commission of the City Council.

The new Dartmouth plant of the Imperial Oil Company was recently inspected by the members of the Rotary and Commercial Clubs and the Board of Trade. The entire property covers 479 acres and the output, when under maximum operation, will approximate 10,000 barrels of oil per day.

Removed Works.—The Lancashire Dynamo & Motor Co. of Canada, Limited, announce that on September 1st, 1918, their head office and works will be located on the south-east corner of Niagara and Bathurst streets, Toronto. The works will be equipped to handle repairs and rewinding of all types of electrical machinery efficiently.

Chicago. — Two big exhaust relief valves, weighing 12,300 pounds each have been shipped to the American Gas & Electric Co., at Peach Bottom, Va., by the G. M. Davis Regulator Co., Chicago. These are 42-inch valves, measuring eighty inches from face to face of the flanges. The bodies and discs are of cast iron and the stems, seat rings and stuffing box glands are of bronze. The water drains are supplied with outside connections, ¾ in. inlet and 1 in. overflow. Heavy brackets cast on each side of the bodies provide means for support. This is a repeat order, as two similar Davis valves were previously supplied to the same company.

Rossland, B.C.—The Consolidated Mining & Smelting Company of Canada, Limited, at Rossland, B.C., is to give a $500 scholarship in 1919 to the son of any employee of the company working at day labor who heads his class in the matriculation examinations for applied science in the British Columbia university, according to announcement just made by Mr. J. J. Warren, managing director of the company. The object of the company is apparently to encourage the technical or scientific education of the sons of its workmen. The constantly broadening field of the company's operations should provide workmen's sons full opportunity to use their scientific training to their advantage and in their own home towns where their families live.

SOME OF THE THINGS SEEN AT TORONTO EX.

Cowan and Co.

Cowan and Co., of Galt, are showing several of their line of woodworking tools—a gear driven upright borer, a hollow chisel mortiser, and box makers' cut off saw forming part of the equipment. A buzz planer with round cylinder and guard is shown and this machine may be fitted with either high speed or carbon steel knives.

One of the latest machines shown by Cowan and Co. is a manufacturing scroll saw in which several valuable improvements have been effected. Upper works, which formerly gave tension to scroll saws, have been done away with and a guide arm carrying a swinging guide plate substituted. This enables the insertion of the saw in a starting hole to be accomplished with a minimum amount of effort and this together with the elimination of inertia effects of a heavy tension mechanism enables a high rate of speed and consequently production to be maintained.

Electric Soldering

The Clemens Electrical Corporation, Ltd., Hamilton, are featuring the J. C. electrical soldering tools. The heat necessary for successful soldering is developed at the spot where needed and in the body of the metal itself by the action of carbon resistance tips connected to a low voltage and large capacity electric current. The source of supply may be either a transformer supplied with the outfit or a storage battery for work around garages, etc.

A special type of solder feeding tool and single prong soldering tool are used for soldering small lug terminals, switchboard wiring and automobile parts.

International Chemical Co.

The International Chemical Co., Toronto, are showing the Betson plastic fire brick products, used for forming jointless one-piece furnace linings in new or old settings. The old lining of pre-brick is stripped away and a lining of the plastic brick is built up by placing it in chunks and consolidating it with a mallet. Gas tight vertical baffles for water-tube boilers are readily made up by the use of this material. Horizontal baffles are also easily constructed.

Amalgatex is a concrete floor hardener, which, unlike paints, forms a chemical union with the cement of the floor and eliminates the wear and dusting so common to concrete floors.

Another product featured by this company is a boiler compound, "Protecto," which has a mechanical action on the scale itself. Water treatment will not entirely prevent scale and corrosion and this preservative forces its way through the scale, crowding off the scale and incrustations and films, the metal protecting it from further action.

For the prevention of air leakage into boiler settings a boiler coating is shown. Protecto coat, as it is called, is a semi-plastic combination of synthetic rubber, long fibred asbestos, gums and non-drying oils firmly adherent to the brickwork and expanding and contracting with it.

The Operators' Point of View

BABBITTING AND SCRAPING HINTS FOR THE POWER HOUSE ENGINEER

By M. H. P.

TO make a bearing ready for pouring, secure the mandrel in position and make tight around the ends of the journal, either with putty or with moistened clay. When putty cannot be obtained, clay worked between the hands until free from lumps and plastic makes a very good substitute. In making tight around the end of the box, particularly where there is considerable space between the casting and the mandrel, take care not to press the putty or clay into the lining space. Should there be ¼ inch or more space some wooden heads should be cut out to fit the mandrel and clamped against the box casting. If it is a repair job and there is neither time or opportunity to fit heads, then rub some putty into a small cord and wind around the mandrel close against the end of the box. The cord will serve as heads, and some more putty daubed on the coils will make everything tight.

Covering Mandrels With Paper

Bearings may be cast direct upon the shaft which is to run in them, but it is better to have a mandrel for that purpose. If the journal must be used, place a sheet of strong, smooth paper around the journal so that the babbitt does not come in direct contact with the metal. This is also excellent practice in all cases where mandrels are used for babbitting single boxes. Where many are poured in succession the mandrel becomes heated and does not chill the hot babbitt, hence the paper becomes unnecessary.

When poured directly upon the journal, babbitt pinches the shaft along the line of division between box and cap, and scraping is necessary to make the journal fit the box after the lining has been poured. The thickness of paper around the journal, combined with the shrink of the soft metal, relieves the journal so that on rough work little or no scraping will be found necessary, the arrangement of the liners giving all the adjustment necessary. On fine work, however, scraping will be necessary. In fact, all fast running and close fitting bearings should be scraped to fit the journal which is to run in it.

Sometimes the soft lining is peened to make it tight in the casting. When babbitt or other lining metal is poured into a cold casting the lining becomes chilled before the iron casting becomes heated, therefore, when the soft lining finally cools it shrinks away from the casting and becomes a loose, rattling nuisance which must be peened to make it tight in the journal bearing casting. Heating the box before pouring in the soft metal lining is a cure for looseness, as the iron casting then shrinks with the soft metal lining on cooling and holds fast when cold.

There is another way of fastening a lining tightly into a cold casting, and that is by using one of the antimony alloys as a lining. Antimony, when alloyed with lead and with some other soft metals, loses the power of shrinking during the freezing process, and like water expands and fills the casting so tightly that there is no rattle or looseness. Therefore, when forced to line a cold bearing, use an antimony alloy. It is for this purpose that the antimony alloy is used for casting printing type. The expansion of the alloy during the instant of solidifying or freezing causes the metal to expand into every corner of the mold. The same is true with the antimony alloy in the journal bearing.

Forming Oil Channels

Oil channels may be formed in the lining by winding small cord around the mandrel. The cord should be of the hard spun variety and preferably should be rubbed smooth with putty before being wound upon the mandrel. The cord

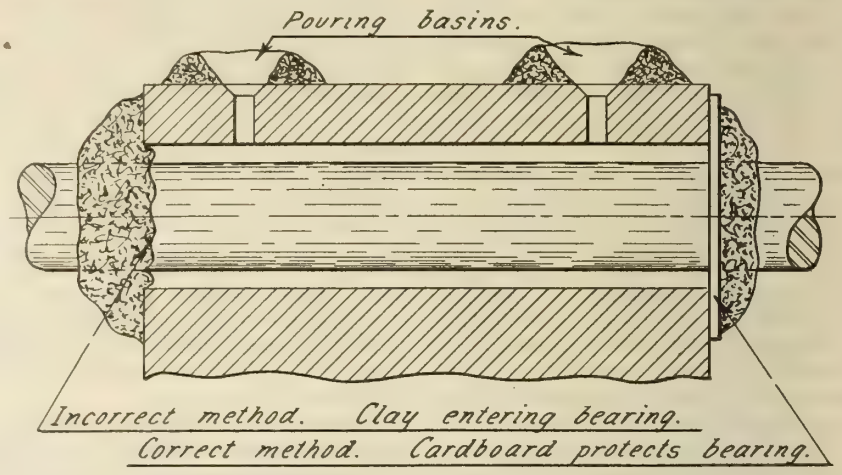

FIG. 1.—RIGHT AND WRONG METHODS OF STOPPING OFF ENDS OF BEARING.

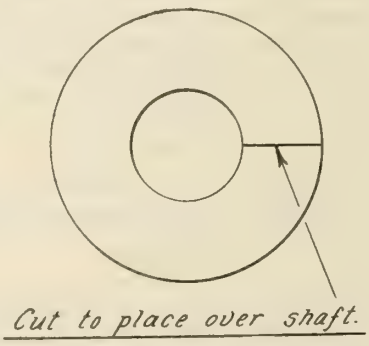

FIG. 3.

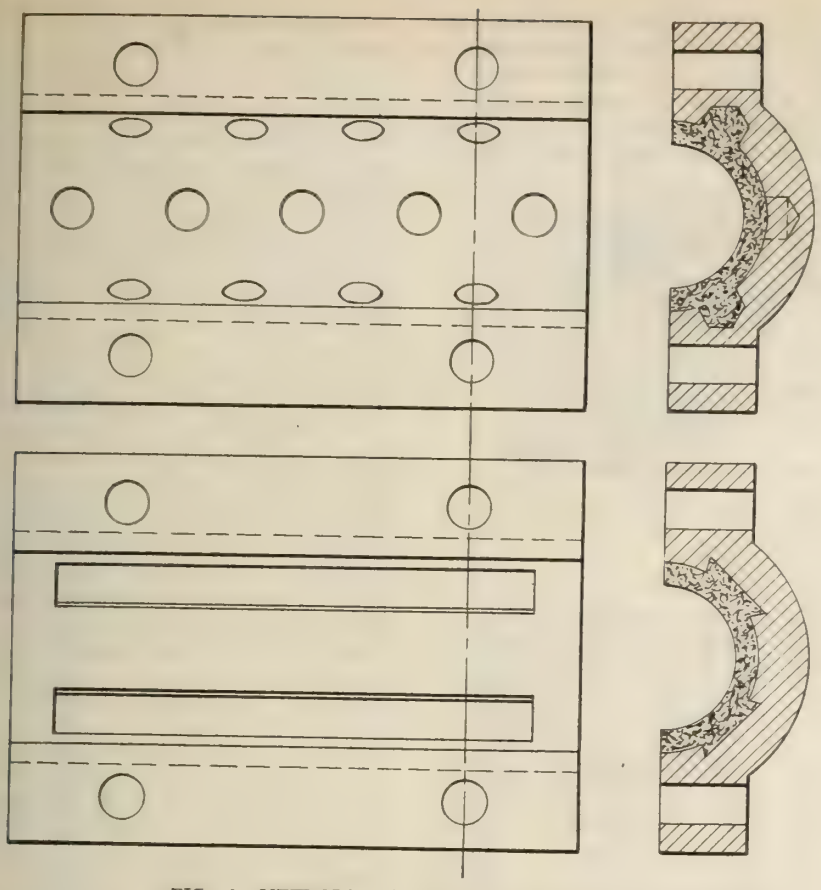

FIG. 4.—METHODS OF KEYING BABBITT IN BEARINGS.

must be wound in the direction that the shaft is to run. It does not work well when a passage must carry oil against the rotation of a shaft. When cap and box are to be poured together, cut two notches in each liner, one notch at one end, then clamp the cap in place, taking care that the liners are against the shaft before tightening down the cap bolts.

If there are holes in the cap for pouring in the lining, besides the oil holes, then proceed to fit a white pine plug in the latter hole, fitting the plug tightly against the mandrel and let it project through the hole in the cap. After pouring, the cap may be easily removed by driving a cold chisel between cap and box, breaking off the metal which connects the cap and box linings through the four notches mentioned. These notches should not be more than ¼ inch on a side, and the section of soft metal lining being small is easily broken by driving in the cold-chisel. The four bits of ruptured metal should be carefully chipped or filed off smooth with the surfaces from which they project. Then drive out the plug in the oil hole and the cap is ready for scraping to fit the shaft.

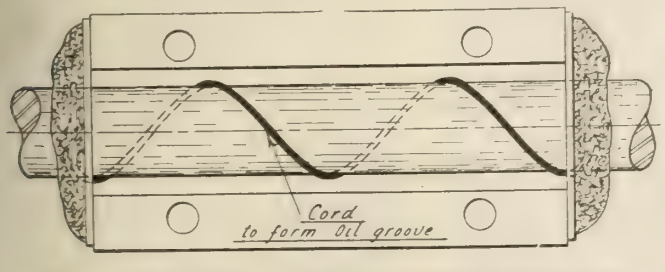

FIG. 5.—THE USE OF A CORD TO FORM OIL GROOVES.

Heating Babbitt Metal

Before pouring a bearing, it is very important that the babbitt metal be heated to the proper temperature. This may be roughly determined by inserting a piece of wood—white pine or similar soft wood—into the hot babbitt and noting the effect upon the wood. It is best to whittle the stick to a smooth, flat surface, similar to the paddle used for stirring paint. The surface of the molten metal should be kept covered with a layer of charcoal to prevent oxidization of the alloy. Thrust the whittled stick through the layer of dust on top of the hot metal and note results to the stick. If the metal is too hot it can be felt to be boiling around the stick, which will be charred more or less, or not affected at all, according to the temperature of the molten metal.

It is certain that the metal is too hot when the stick trembles in the hand and smoke rises from the submerged end of the stick. When there is scarcely any trembling to be felt in the stick while it is immersed in the hot babbitt, then the alloy is ready to pour. If the stick is not colored at all and metal almost adheres to the stick, then the metal is not hot enough and it will not flow properly if poured at that temperature.

When babbitt metal is at the right temperature the stick will be faintly charred after being immersed three or four seconds in the molten metal. Two or three tests will blacken the stick even when the metal is not quite hot enough to pour, therefore it is best to whittle a new surface on the test-stick after each immersion.

Pouring Soft Metal Bearings

Do not heat soft metal too hot, zinc is easily driven out of an alloy by too high temperature when melting, lead soon turns into dross upon exposure to the oxygen of the air when melted, and the higher the temperature of the melted metal the faster it will be rusted out by exposure to the air. It is for the purpose of preventing this loss of some of the metals that the surface of the molten alloy is kept covered with charcoal. But when the alloy is overheated, then oxidization proceeds much more rapidly and much metal is lost.

Do not skim the surface of the metal until it is clean of all dirt. When the ladle is tipped up, the bit of iron forms a floating dam which effectually prevents the covering of dirt from flowing out of the ladle, while the molten metal has free passage under.

When babbitt metal is melted in a pot, the alloy may be dipped out with ladles as required for pouring, and before dipping the ladle into the pot, push the covering to one side with the ladle, then pass the ladle below the surface of the alloy, taking care that the ladle is entirely submerged. Then lift the ladle out quickly and an excess of metal will be forced up by and above the ladle. As this excess of metal flows away, it forces back the charcoal covering on top of the alloy, and the ladleful of metal comes out of the pot clean, with no signs of dirt.

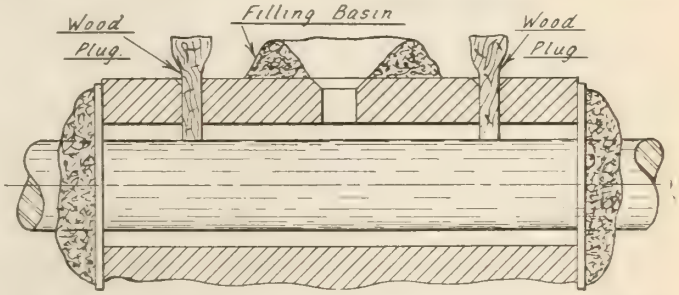

FIG. 6.—THE USE OF WOODEN PLUGS TO FORM OIL HOLES.

The metal must be poured very quickly when thus dipped up clean, for the reason that oxidization is going on all the time. Hasten the pouring operation once the

metal is heated and exposed to the air ready for pouring. The pouring must be done steadily.

Pouring Thin Solid Boxes

It has already been stated that the temperature of the alloy, when poured, should be just high enough to slightly char a soft wood stick. But when thin solid boxes must be poured, and there is a long narrow or thin space to be filled with soft metal, then it is sometimes necessary to pour the metal hotter than described. In such cases the metals to come in contact with the soft metal should always be heated as much as possible before pouring in the lining. When a ladleful of metal fails to fill a box, do not try to fill the box by pouring hot metal on top of the cold. Take down and chip out the partially filled bearing, set it up again, and pour from a supply sufficient to fill the bearing.

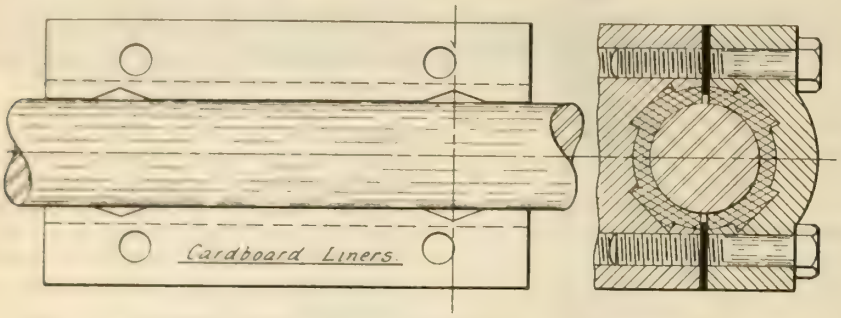

FIG. 7.—SHOWING THE USE OF CARDBOARD LINERS IN POURING A SPLIT BEARING.

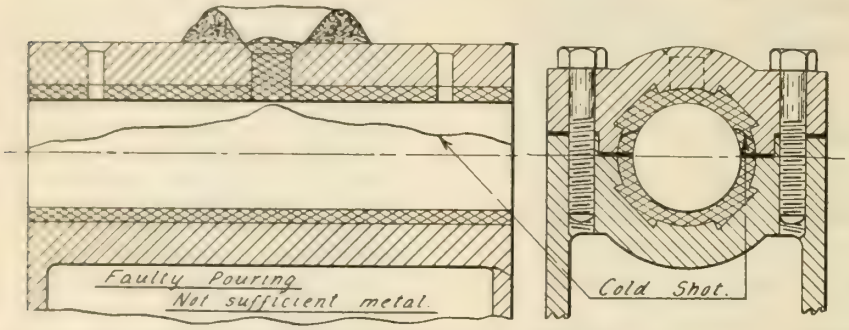

FIG 8.—THE RESULT OF FAULTY POURING. NOT SUFFICIENT METAL IN LADLE TO COMPLETE THE BEARING AT ONE POUR.

Scraping Bearings

In order to make a first class babbitting job the scraping operation is necessary. Even for rough work, should it be possible to make a good bearing without scraping, a better one can be made if the operation of fitting the bearing to the journal be carefully followed out. unless the journals are properly fitted to their bearings it requires a great deal of preliminary running so that the bearing will not heat. When a shaft hits a bearing only in two spots, at opposite sides and ends of a bearing, it cannot be expected that the shaft will run cool and steady in that bearing.

When a shaft is made up in a bearing and given a turn or two, and black spots appear in two or three parts of the babbitt with no marking elsewhere, then it is sure evidence that the shaft touches the bearing only at those two or three spots. The remedy is to remove the metal at those points until the shaft touches at four or five places instead of at two or three. Then remove the four or five and secure a bearing at eight or ten. Continue this work until the shaft has a bearing in many spots. In this way innumerable points of bearings could be obtained between the shaft and the babbitt, and it could be assumed that they touched each other at all points and that the contact between them was practically perfect.

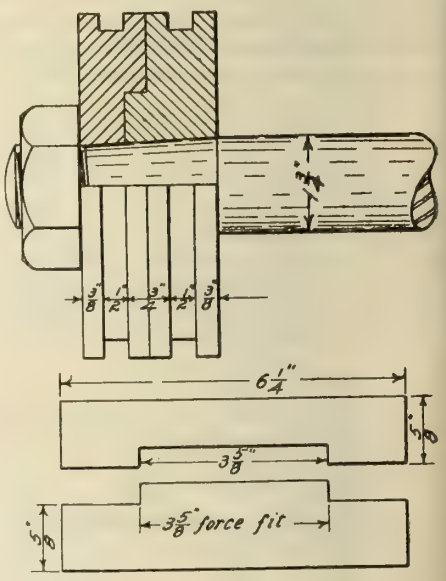
When fitting a bearing to a shaft as above, the blackened spots are removed by scraping, hence the name of the operation becomes that of scraping a bearing. A good job of fitting as above described may be done by the use of a common carpenter's chisel. By the use of this tool the blackened spots may be removed. A little plumbago or red lead mixed with oil and rubbed on the shaft each time will leave new spots to scrape off and the operation may be continued indefinitely.

EMERGENCY REPAIR TO PISTON

By J. H. HOULDSWORTH

Emergency repairs are frequently an important factor in maintaining the efficiency of a machine shop or power plant. Under certain conditions it is very often necessary that repairs be made at once to avoid shut down of the plant or one of the departments. Where equipment must be operated without rest the maintenance of such requires the most careful attention on the part of the engineer in charge.

The accompanying sketch shows the repairs made to a piston when the same was required at a time when all foundries were closed. This piston was used in a pump which was operated twenty-two hours per day, and the break developed at a time when a replacement in the ordinary way was impossible owing to the fact that it happened about noon on Saturday, with all foundries closed for the week. Repair was absolutely essential so some method had to be adopted to get the pump running again. After dismantling the pump it was found that the rod was also bent. The latter was not so serious, as the straightening was soon accomplished. Having a look around the shop we discovered a couple of old balance weights with a diameter of 7½ inches and a thickness of 2¼ inches, from which we made a very satisfactory piston as shown. We had two lathes available, so one was set to work to rough down the weight to about ⅛ inch of the required diameter of 6¼ inches, and the hole bored ⅛ inch smaller than the small end of the taper. The other lathe was then started on the second casting, this being roughed in a similar manner, with the exception that the hub of one was made a force fit for the other. One of the pieces was then removed and pressed into the other without removing the latter from the face plate. The two were then held firmly together by means of suitable clamps, and the center hole bored out to fit the taper end of the rod. After securing the piston on the rod the rod with the piston was placed on the lathe centers and the head finished to the proper diameter and the piston ring grooves turned in. We were able in this way to have the pump working before night, thus avoiding the necessity of obtaining a new pump. The pump was shortly afterwards replaced by one of greater capacity, and the old one sold, but the latter is still in good working condition, no trouble having developed from the impromptu repair.



PISTON REPAIR SAVES SHUTDOWN.

METHOD OF SAVING FUEL

By James Creeney

I noticed in the plant which I have charge of, the firemen, when checking the fire closed the ash pit doors; one day I noticed the increased current of air that went rushing through the air holes in the fire doors when the ash pit doors were closed, this made me think. We all know that the pressure inside a furnace is much less than the atmospheric pressure on the outside and for this reason cracks and other holes in the boiler settings lower the efficiency of the furnace by admitting cold air through these cracks. Now, by closing the ash pit doors the path of least resistance was stopped by which the air supplied the demand of the chimney, therefore the pressure inside the furnace must have been greatly decreased, causing a much greater leakage of cold air through the settings and rapid lowering of the furnace temperature. I fixed up the dampers in the uptake pipe so that the firemen could check their fires by closing it and leaving the ash pit doors open; by doing this we increased the air pressure inside the furnace and therefore decreased the amount of cold air entering through cracks. I have not made an evaporative test, but feel confident that a coal saving and less boiler strain is the result of the change. Some of our engineer friends will say that there should be no holes or cracks in the boiler setting to admit cold air, but in the absence of a flue gas analyzer it is next to impossible to know whether they have all been stopped or not.

ENQUIRY RE GRADED CERTIFICATES

A correspondent enquires if the proposed second class grade of certificate was to be issued without further examination to holders of present certificates.

The proposed certificates were intended to be issued to holders of the present licences upon the passing of an examination, this examination to be purely voluntary, the present certificate remaining the official government qualification. —Editor.

GRADED CERTIFICATES

By F. T.

The subject of graded certificates for engineers has again been occupying the attention of both engineers and legislators. This much-vexed question has a number of different angles of approach, and while in some cases and under certain conditions graded certificates may be of great value to both engineers and manufacturers, under different conditions they may be worse than useless. The agitation for this change in the licensing law has come mostly from the better class of engineers themselves, and has been opposed by the unions for their own reasons. Let us examine, from a common sense point of view just what advantages there are to be derived from the issue of different classes of qualifications.

In the first place let us get away from the idea that each man who has passed a certain kind of examination is equal to every other man who has gone through the same test. The individual retains his own characteristics, and no two personalities are alike. All that any graded certificate can do is to guarantee that the holder has had a certain amount of practical experience and is possessed of a certain amount of fundamental knowledge of his business. How far that knowledge goes depends upon the standard set by the governing body, and the standard of the examining body itself. A certificate cannot give any guarantee as to the holder's ability to handle men, or his ability to make a success of any plant he may be appointed to take charge of. What a certificate can do and should do is to indicate that the holder has had ambition and energy enough to get the highest endorsement of his qualifications that he could, and that any plant owner who engages him knows he is getting a man of definite practical experience and a definite standard of technical knowledge. This object can only be achieved by the issue of graded certificates by a competent body of examiners, and this is the most important point to watch, because it has not infrequently happened that the examiners have not been up to the standard of the examined. In one province that has a system of graded certificates the examinations do not achieve the aim they were set for, due to the conditions under which they are held. In this case the candidates in the various grades have to answer in writing a varying number of questions the lower grade having the least number. The next grade answers the questions previously asked and a few more, slightly more difficult, and so on through the four grades. These questions never vary, the result being that the questions and answers are common property, to be obtained by asking one's immediate friend. Such a system as this defeats its own object, as the only thing it guarantees is that the holder of a certificate has been engaged in stationary engineering for a certain time, its value as a gauge of his technical knowledge being non existent. In the same way, a certificate which lumps all men together regardless of their experience and knowledge is equally at fault. Consider a man coming from any province or country where a high standard of graded certificate is in force to a district where there is but one grade. His superior knowledge and qualifications are immediately discounted as far as his certificate is concerned, and while that man may soon prove his worth when he secures employment, until he does he is open to competition from men much below his own standard.

It would seem then that it is highly advantageous to the high grade engineer to secure graded certificates, and equally advantageous to the employer. To the trades unions it presents the objection that it makes one man better than another, with which they cannot agree, and to the politician the voice of the trades unions, with their accompanying votes, is loud in the ear. It is interesting in this connection to hear that a conference is taking place in Winnipeg at the present time, having as its object the drafting of an uniform examination law for all the provinces.

READER'S QUERY

Question—We have a large tank for fuel oil, 6 ft. dia. x 33 ft. long inside dimensions. The surface of the oil is 4 feet from top of tank, and I wish to know the quantity in gallons remaining in the tank?—A Subscriber.

Answer—The contents of this tank when full would be—6 x 6 x .7854 x 33 = 933.05 cub. feet. As there are 6.25 gals. to one cub. foot volume 933.05 x 625 = 5831.56 gals. In order to calculate the amount of oil remaining in tank at any level, it is necessary to make a series of calculations, covering half the diameter of the tank, because all levels below the centre line of tank will be covered by the calculations made for the upper half. In dealing with fuel oil, it is best to have as close measurements as possible, giving the quantities at each difference of 1" in height. Now when the level of the oil is 1" from the top of the tank, we have a certain volume of the tank empty, and by calculating this volume, and subtracting, we get the amount of oil remaining. The calculation is as follows: Area of segment multiplied by length = volume. A good rule for the area of a segment is: $\frac{4h^2}{3} \times \sqrt{\frac{d}{h}} - .608$

where h = height of segment.
d = diameter of circle.

Now the height of the segment is one inch, the height from surface of the oil to top of tank, and the diameter is 72 inches, so we have

$\frac{4 \times 1 \times 1}{3} \times \sqrt{\frac{72}{1}} - .608 = 11.22$ sq. inches.

The area of the segment being in square inches, we must reduce the 33 feet to inches, before multiplying 11.22 x 396 = 4443.12 cubic inches. Divide this by 1728 to bring to cubic feet 4443.12÷1728=2.57 cubic feet. Multiply by 6.25 for number of gallons=2.57 x 6.25=16.06. That is, 16.06 gals. have been taken out, leaving 5831.56—16.06 = 5815.5 gals.

This method can be used for every point required. Let us see how much oil is contained in the tank when surface of oil is 4 feet from top of tank. Instead of taking the volume of the empty space, we will take the volume of oil remaining. We have $\frac{4h^2}{3} \times \sqrt{\frac{d}{h}} - .608$. Putting the figures $\frac{4 \times 2 \times 2}{3} \times \sqrt{\frac{6}{2}} - .608 = 8.208$ sq. feet. 8.208 x 33=270.87 cubic feet.

270.87 x 6.25 = 1692.9 gals. Say 1693 gals., which is the answer our correspondent wants.

To show how close a measurement this method gives, takes the 3 foot level, or the tank half full. We have seen that the total quantity it can hold is 5831.56 gals. Therefore, at half full, it must contain 2915.78 gals. Check this by our calculation.

$\frac{4 \times 3 \times 3}{3} \times \sqrt{\frac{6}{3}} - .608 \times 33 \times 6.25 = 2920$ gals.

This shows an error of 4.22 gals., or 1.44% at the point where the greatest error can happen. Do not forget that the quantity of the oil does not vary in direct proportion to the height, but to the area of the segment exposed.

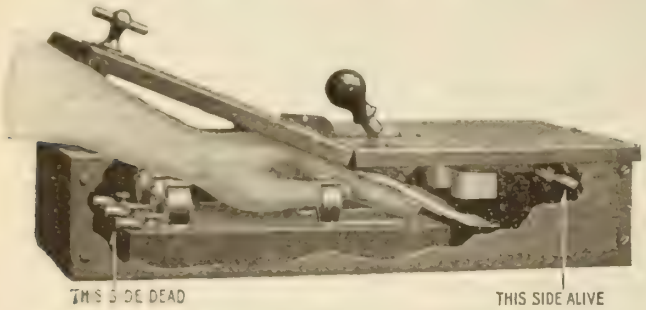
T. H. F.

John Dennis, who has been on the Government Inspecting staff, has resigned to take up the position of Master Mechanic at the St. Lawrence Starch Co., at Port Credit.

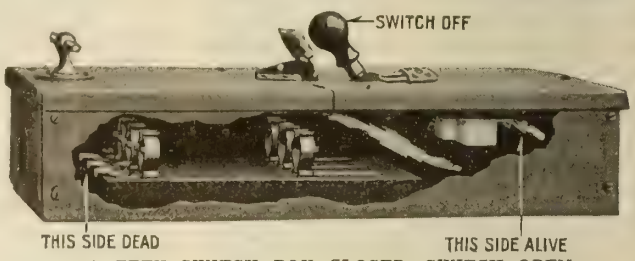
SAFETY SWITCH

In many steel mills, factories, mines and similar industries where most of the workmen have little knowledge of electricity, it is desirable to use switches having no live parts exposed or accessible in the ordinary operation of the switches or when replacing fuses.

This is fully accomplished in the Krantz Auto-Lock Switch, marketed by the Westinghouse Electric & Manufacturing Company, which is intended for use on main circuits or wherever an ordinary knife switch is applied. The switching parts and fuses are enclosed in a steel box, the cover of which is in two parts, one being screwed on to form a permanent covering for that end of the box containing the switch, and the other part being hinged so as to swing back and permit the renewal of fuses, which are located in this portion of the box. An ingenious latching mechanism makes it impossible to open the cover without first throwing the switch to the "off" position and rendering all fuses and other accessible parts dead. Thus fuses may be replaced at any time with absolute safety. As long as the door of the case is open the switch contacts can not be closed.



SWITCH, SHOWING IMPOSSIBILITY OF TOUCHING LIVE PARTS.



SAFETY SWITCH BOX CLOSED, SWITCH OPEN.

By using a padlock, the switch handle can be locked in the "off" position, making it impossible for any one to close the switch except the person holding the key to the padlock. By using another padlock the cover may be locked shut, so that the fuses cannot be tampered with. Either of these padlocks can be used independently of the other so that the switch cover can be locked shut with the switch either "on" or "off", or the switch can be locked in the "off" position with the cover either locked or open.

Contact is made by means of a laminated spring copper brush, double ended, with auxiliary arcing contacts at each end. The outer leaves of the brush are bronze to provide additional spring pressure.

The stationary contacts are of hard-drawn copper and are mounted on slate bases, one of which in the fused switch carries one of the fuse clips, while the other forms the terminal block for the incoming line and is mounted under the stationary portion of the cover.

The operating mechanism is galvanized steel of the toggle type, and is attached to the under side of the stationary end of the cover. This mechanism can be easily removed for inspection by re-

In closing, the pressure between the contacts causes the laminations of the brush to spread apart, giving it a wiping or self-cleaning action.

The double-ended brushes provide a double break, dividing the arc between the two ends, each of which is provided with a separate arcing tip.

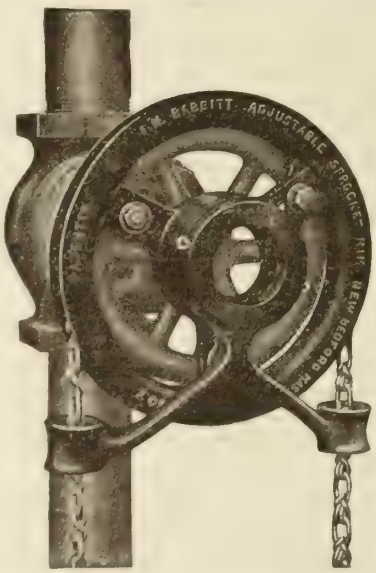
In the closed position the switch is held in positive contact by throwing a toggle over the center. A spring provides a quick-break for opening, the mechanism being independent of the operating handle.

These switches are supplied for 250 500 and 600 volt, for either alternating or direct-current, service, and in capacities up to 2,000 amperes.

The safety features of this switch have been recognized by the American Museum of Safety, which has awarded it a gold medal and special mention.

AN IMPROVED RIM FOR CHAIN-OPERATED VALVES

The Babbitt adjustable sprocket rim eliminates entirely the inconvenience of carrying heavy ladders and appeals strongly to engineers, since chain operation is much easier than the old-fashioned "ladder" method. In addition to this, the element of danger from the use of a ladder is no small one, and the last report of the Massachusetts Industrial Accident Board showed over 900 accidents due to falling ladders. In the engine room where the floors are frequently oiled, there is particular danger of the ladder slipping.



RIM FOR CHAIN OPERATED VALVES.

A recent improvement on this rim is a chain guard consisting of two arms through which the chain passes. The arrangement can be clearly seen in the illustration. In any ordinary installation this guard to prevent the chain from jumping off the wheel is entirely unnecessary, but on board ship, or where the valve stem is not horizontal or where other unusual conditions exist, such a device is sometimes advisable. Steam Specialty Co., of New Bedford, Mass.

Electric heating presents a very desirable load for the central station, because it operates a high load factor, takes, for the larger installations, a comparatively large number of kilowatt-hours at one point with relatively long hours of usage, and is practically a non-inductive load resulting in a high power factor. After the connection is once made, very little attention is required on the part of the central station, and, where necessary, the load can be adjusted so as to be largely off-peak.

There is considerable work for the mechanical engineer in conservation of heat units around an oil refinery and in most all branches of the oil industry. There are large refineries operating to-day and using four to five hundred per cent. more fuel than is necessary to do the work. It is possible to save, by proper distribution of the heat available around the oil refineries in the United States, at least 2 per cent. of the total crude oil put through these refineries. There are large oil refineries operating to-day that are using as fuel 4 per cent. of the crude oil run through them to do less work than the plant described is doing on 1.1 per cent. of the crude oil run through as fuel, and the losses due to non-condensable gases, &c., are 2 per cent., against 0.75 per cent.

Allied Tungsten Pool.—An international agreement for the pooling of all available tungsten among the United States and the Allies, reached through the Inter-allied Munitions Council at Paris, was announced by Chairman Baruch of the War Industries Board. Its terms will be made public if the arrangement is finally approved by President Wilson. Tungsten is produced largely in Colorado, but some comes from South America and Sweden and other European countries. Distribution of the supply probably will be directed by the War Industries Board.

WINNIPEG MEN ARE ANXIOUS ABOUT SUPPLY OF ALBERTA COAL THIS WINTER

THE Winnipeg City Council committee, after visiting the Alberta coal areas, and looking into the prospects of securing Alberta coal for this winter, reported in part as follows:

"Regarding the question of cost of producing a ton of coal, your committee found difficulty in arriving at a true estimate as to the actual cost of production. We met a number of mine operators, and it was only in one or two instances that we were shown the actual cost sheets. Such instances could not be taken as an average cost of producing one ton of coal at the mine head because cost of mining varied from mine to mine. In some mines for instance, the miner will receive 67c for mining and loading one ton of coal, while in some other districts it runs as high as $1.33. Again, some mines require very little timbering to be done, and in other mines cost of timbering will run as high as 35c per ton.

"The items just mentioned are determined largely by the natural coal deposits in the mines. The impurities contained in coal deposits in some mines are greater than others, this also having an effect on the cost of production.

Get $7.05 a Day

"Your committee also enquired into the wages of the men working in the mines. In the Lethbridge district the average wage earned by the men who worked on contract and were known as "contract men" is $4.55 for a full working day. In the Drumheller district are average wage earned by 'contract men' is $7.05 for each working day.

"It is well to point out here that the coal sold from the Lethbridge district costs more at the mine head than the coal from the Drumheller district.

Cost of Production

"Mr. Armstrong, while having the power to determine the price of coal at the mine heads and determine rates of pay to the employees in the mining industries, informed us he did not have any figures to show what it costs to produce a ton of coal at the various mines. One day prior to our first interview with him, Mr. Armstrong had sent a request to the Dominion Fuel Controller to audit the books of the various mining companies in order to try and determine the cost of production.

"Regarding the second phase of our inquiry, the quantity of coal available for shipment from the Alberta mines, your committee begs to submit the following facts and figures, namely:

"In 1916 the exact total of the coal produced in Alberta was 2,172,801 tons.

"In 1917 the figures were approximately 2,125,000 tons. These figures are for lignite coal suitable for domestic purposes.

What Mines Produce

"According to Mr. Sterling, chief inspector of Alberta mines, the total production for 1918 is expected to yield 3,225,000. After careful investigation of the needs of the three prairie provinces we are of the opinion that the above quantity would be sufficient to meet the requirements, but the following facts cannot be too strongly emphasized. In order that the full amount required to meet the needs of the three prairie provinces be obtained, there must be continuous production at the mines, such production can only continue so long as orders are received from the dealers and consumers. There are no facilities at the mines for storing coal and if such were the case we believe that the cost would be considerably increased per ton. At present coal is shipped direct from mine to purchaser, storage at the mines would mean that coal would have to be handled at least on two or more occasions, this accounting for the extra cost if such were the case and, further, if large quantities were held in reserve it would almost be impossible to obtain the necessary transportation at short notice. It is on account of this fact that we beg to emphasize the necessity of ordering coal by all who are able to do so and to store same in proper manner.

"Regarding the labor situation, your committee found, generally speaking, an ample supply of men available for the time of the year, and whilst most operators stated their desire for increased staff and output, we believe that as soon as harvest is over the labor supply will be sufficient to meet requirements, and the amount of freight cars allotted by the railway companies. In addition to the above and after meeting with several of the employers and officials of the miners' unions, there is nothing at present that would lead us to believe that the men would cease operating the mines during the year.

Coal Values

"Your committee, on the question of the quality of coal of Western Canadian mines, had difficulty in obtaining relative value of Western coal and anthracite coal. A great deal depends on the knowledge of the use of Alberta coal. Different persons using the same quality of coal obtain different results. It is admitted by all interested in Alberta coal that its value is not as great for heating purposes as anthracite coal, but such estimates vary from 25 to 75 per cent."

Demand For Tools.—Several firms in Manchester have recently inspected a number of Canadian catalogues on file in the office of the Trade Commissioner at Ottawa, and they have undertaken to correspond with manufacturers in the hope that future, if not immediate, business will result. From time to time opportunities for the creation and extension of trade in all kinds of tools have been reported, and Canadian manufacturers are advised to keep in touch with the requirements of the British market.

SUBMERSIBLE PUMPS IN SALVAGE WORK

One of the interesting features of modern ship salvaging appliances is the submersible motor pump. These pumps are caried on the salvaging vessel, and when in use are lowered into the hold of the sunken vessel, which it is desired to pump out, and supplied with current from the engine room of the salvage steamer. They are made in convenient sizes, from 4" to 8", the smaller size having a capacity of 150 tons an hour, against a head of 70 feet, while the 8" size is capable of throwing 350 tons of water against a head of 70 ft. per hour. They have proved effective in operation. A good instance is the case of a torpedoed vessel recently salved. The cargo of this ship was valued at $15,000,000, mainly food stuffs. After the torpedoing, an effort had been made to beach the vessel, but she sank before getting high enough. The damage consisted of a hole between No. 1 and 2 hatchway, 40 feet long by 28 feet deep. The submersible pumps were used in this case very advantageously. The pumps were placed in position, and holes drilled through bulkheads of No. 4 and 5 holds, engine room bulkhead, allowing the pumps to pump the after end clear. The 'tween deck hatches in damaged part were closed, and the pumps put to pump out the forward end. Enough water had now been pumped out to enable the ship to be moved higher up the beach, with the result of drying out the shelter and 'tween deck. The final stage was to discharge enough cargo to allow the ship to be floated off the beach, and taken to a repairing port.

Approves Rate Increases.—Director-General McAdoo has approved the application of the American Railway Express Company for further rate increases estimated to yield $23,670,000, and has sent the proposal to the Interstate Commerce Commission for final action. The Commission announced that public hearings on the matter will begin Tuesday, October 9.

Guelph.—At the regular meeting of the Light and Heat Commission at the city hall, Manager Heeg submitted the schedule he had prepared showing where power could be saved by the co-operation of the power-users of the city. The schedule, which is not a very complicated one, shows that the greatest saving of power must be accomplished between the hours of 5 and 6 o'clock in the evening, when the load is at its highest. This schedule, which has been concurred in by the manufacturers, who are the heavy users of power, and which was also approved by the Commission this morning, will go into effect at once. Notices will be sent out to all power users to that effect. The chief object of the schedule is to allow the local munition plants all the power they require.

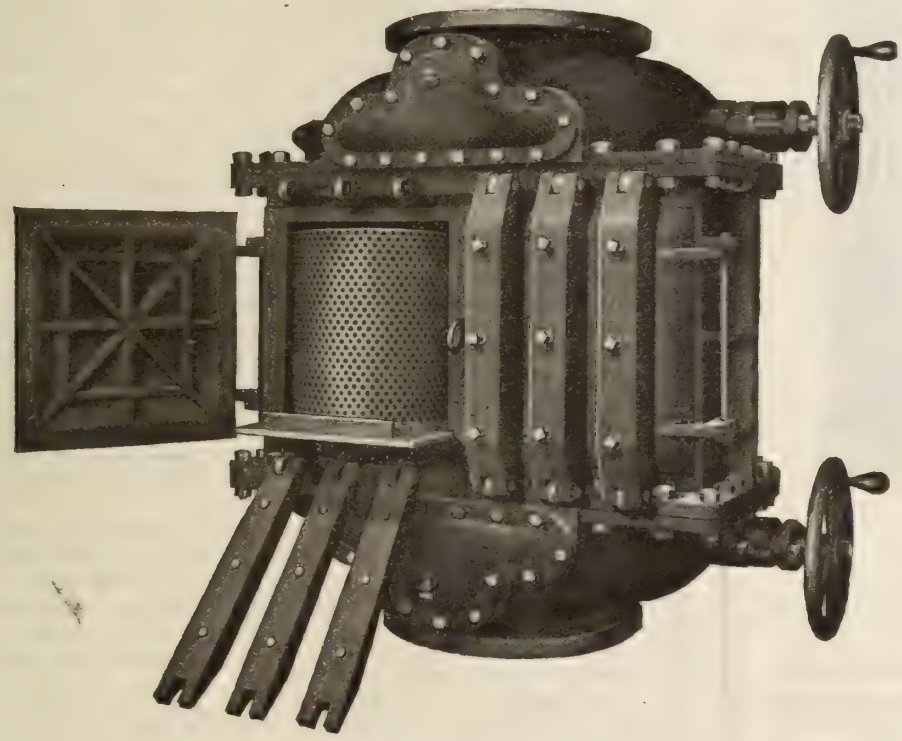
TWIN STRAINERS

eliminate clogging of pumps, condensers and other water-handling machinery



A TWIN STRAINER can't be clogged up, for when one basket is fouled with any sort of solid matter, a clean basket is put into service by simply moving two valves. The dirty basket can then be lifted out, carried to a convenient place, cleaned and then replaced in the Strainer—all this without interrupting the flow for an instant.

Full particulars in Bulletin "A," which will be sent on request

These are a few of the features of the

STEAM TRAP
SARCO

The principle employed in the Sarco makes it simplest in construction. Only one moving part. No levers, gauges, springs or other trouble makers.

In the center of the Sarco is the cartridge containing a spirally corrugated tube which is surrounded by a highly expansible fluid. On the lower end of this tube is carried the valve head.

Temperature changes immediately expand or contract the fluid contained within the cartridges and this produces hydraulic power to open or close the valve.

No loss of steam. No danger of freezing, clogging nor sticking. Used as an elbow or bend—no pit digging nor platform required. Same capacity as any other trap with equal inlet openings. Very much lower in price.

30-day free trial will prove.
Send for circular No. J 6.

NEW REGULATIONS FOR UNIFORM CONSTRUCTION OF ALL BOILERS

WINNIPEG.—The conference of steam boiler inspectors, which has been in session in the city for the past two weeks, concluded its business, and the visiting delegates were entertained at a banquet at the Royal Alexandra. The chair was occupied by Hon. G. W. Grierson, provincial minister of public works, who had on his right Hon. A. W. Armstrong, commissioner of public works and mines for the province of Nova Scotia; Hon. T. C. Norris, premier; S. C. Oxton, deputy-minister of public works, and several representatives of local boiler firms. After dinner and the toast of "The King," short speeches were given by Hon. G. W. Grierson, Hon. A. W. Armstrong, Hon T. C. Norris, J. Peck, of British Columbia, R. N. Blackburn, of Saskatchewan, D. M. Metcalfe, of Ontario, W. J. Fulton, of the Dominion Radiator Company, F. S. Murdoch, of the Vulcan Iron Works, and W. C. Mager, of Ontario.

The object of the meeting was to discuss and draft a uniform code of regulations for the construction and inspection of steam boilers. Some of the western provinces have had a code, but it was difficult to meet all requirements and made it almost impossible for manufacturers to produce a boiler that conformed to all conditions as to pressure. The suggestion for uniformity originated in Saskatchewan some eight years ago, where the first attempt was made to arrive at a uniform code at a conference held at Regina in 1910. A code was then drafted, but some of the provinces not then being represented, it was difficult to compile a series that would be acceptable, but the draft was adopted by the governments of Alberta and Saskatchewan. However, the movement was continued and two years later the province of Ontario adopted the code, and in 1914 a second conference was held in Toronto, when the code was revised and new matter added. It was not then possible to complete the work and further consideration was deferred till the province of Manitoba recently became interested and decided to adopt a code for the province. The government was naturally anxious to adopt a code that would be acceptable throughout the Dominion, and the present conference was largely due to the initiative of R. A. Stewart, chief boiler inspector of the province, and the active interest of the department of public works. The sessions convened in the quarters of the local bureau of labor and have continued for two weeks, under the chairmanship of J. Peck, the representative of British Columbia, and the secretaryship of R. N. Blackburn, the representative of Saskatchewan. The official delegates were: Hon. A. W. Armstrong, commissioner of public works and mines, Nova Scotia; E. F. Valiquet, superintendent of the Montreal water works; Dr. Riddell, head of the Ontario bureau of labor; and D. M. Metcalfe, chief boiler inspector of the province; R. N. Blackburn, chief inspector for Saskatchewan; F. W. Hobson, chief inspector for Alberta; J. Peck, chief inspector for British Columbia, and R. A. Stewart, chief inspector for Manitoba.

The members of the conference are greatly pleased with the courtesies extended by the local government, through both Hon. Mr. Grierson, minister of public works, and the deputy, S. C. Oxton, and consider that the code of regulations adopted are equal to any such measure enacted by any government, and believe they will be acceptable to all provinces, as also by manufacturers and others interested. The code will be submitted to the government of each province, and there is every prospect that it will be endorsed and enforced by order-in-council so as to go into operation in January. A few of the members have already returned to their homes, and others leave to-day for the east and west.

HINTS ON STORING COAL

During the present year, consumers are storing coal as long in advance of winter as possible. It is important, therefore, that they should take precautions in the storage if loss through spontaneous combustion is to be prevented. There are certain simple methods of handling coal that experience has taught are necessary to obviate such a misfortune, especially where considerable quantities are to be stored. Thus, coal should be so piled that air can circulate through it freely to carry off the heat, or so closely piled that air cannot enter the pile. Low piles are preferable if space permits and alleyways should be provided to facilitate moving the coal quickly. Occasional ventilation pipes are ill-advised, but the practice of placing such pipes close together has been tried in Canada with effective results. Different kinds of coal should not be mixed in storage.

In quenching fire in a pile, water should only be used if there is an ample supply, a small amount is ineffective and very dangerous.

Where available, under-water storage is recommended as it entirely eliminates spontaneous combustion. The preparation of a suitable pit for this method of storage is sometimes costly, but old quarries, clay pits and even prairie sloughs have been used. Deterioration of coal stored under water is negligible and it absorbs very little extra moisture. —L. G. D.

Matheson, Ont.—The construction of a complete system of electric light and power at an approximate cost of $10,000 is having the consideration of James A. Lyttle, deputy clerk of the municipality and ratepayers of the town.

Hamilton, Ont.—The old boilers taken from the court house here have been reduced to pick-up-and-carry scrap without the blow of a sledge hammer. Acetylene gas jets were employed to cut up the old shells and piping. The first boiler was in pieces within two hours from the time the flame was applied.

In the new bulletin K-303, issued by the Canadian Ingersoll-Rand Company, Limited, the class EL-2 two-stage straight line compressor is described. The bulletin indicates the advantages of the tandem arrangement for certain classes of work where economy of space is to be combined with the advantages of two-stage compression, and goes on to give details of construction, including the Leaf Valves and other features. The bulletin concludes with a note on the short-belt drive, with which this type of compressor can be furnished and which has distinct advantages where space is at a premium.

Closed Large Contracts.—Several large contracts have been closed by the Chapman Double Ball Bearing Co., Ltd., Toronto. An order covering gun mounts, and for shafting in the factory manufacturing them was secured for the Dominion Steel Products at Brantford, where contracts running to about $5,000,000 have been placed for the U. S. government. The bearing in this order will run close to $60,000 for the transmission outfit. The Chapman people also have the contract for the Dominion Shipbuilding Co., Canadian Airplane and British Forgings. Other large orders placed recently included 2,000 bearings in the T. Eaton Co. building on Alice street. The Ford Co., Canadian plant's order was for 4,000, while 1,500 were placed in the Dominion Arsenal at Lindsay."

THE LIFE of a marine boiler depends to a certain extent on the care and attention bestowed on it during the first few months of its existence, provided that the plates have been properly treated at the building of the boiler—that is, all mill scale removed and the plates kept dry and free from atmospheric corrosion. The mill scale, if not removed has a very irritant action on the clean metal of the boiler, and is most hurtful to the plates if allowed to remain on them. When new boilers are put in under the varying conditions in temperatures which are found on ship board, the greatest care and attention is needed for the first period of working if the boilers are to be kept free from corrosion; the new metal of the boiler at this stage being most open to attack from all sorts of corrosive agencies. It is advisable on the first voyage to put into the boilers before closing them up 5 lb. of lime per 1000 I.H.P., and afterwards for a period of about six days 2 lb. of lime per day per 1000 I.H.P. should be passed through the hotwell as milk of lime, and 1 lb. of lime per day per 1000 I.H.P. during the remainder of the voyage.

Peterboro.—The Hydro-Electric Power Commission has notified the city of its intention to spend $1,250,000 in the erection at Ranney's Falls, Campbellford, of a power plant that will produce from 8,000 to 10,000 horse-power. The work will begin this Fall. The completion of the work will relieve the power situation in this district. When the Quaker Oats Company informed the council that it would require for its own use the surplus of 1,500 horse-power which it had been supplying the city the visible shortage of power in this city and district reached a crisis.

Geo. W. Crossan, surveyor, department of the naval service, has been appointed marine manager of the Halifax Shipyards, Ltd., Halifax, N.S. Mr. Crossan is well known in Toronto and surrounding districts, saving sailed on the Great Lakes after coming to Canada, and has taken several ships overseas since the commencement of the war. He served his apprenticeship in Napiers on the Clyde, now Beardmore, Ltd., and sailed as chief engineer of several large ships before making his permanent residence in Toronto over eight years ago. Halifax Shipyards, Ltd., have under contract with the government to build three 10,000-ton ships, and a commencement will be made early this autumn.

LARGE BALL BEARING CONTRACT

The Canadian S K F Co., 47 King street West, Toronto, has received an order for S K F ball bearing hangers for the new shop being erected by the Leaside Munitions Company at Leaside, North Toronto. This contract will cover over 400 ball bearing hangers, and constitutes the largest order for hangers ever placed in Canada. It is significant in the development of anti-friction bearings that they are being universally adopted in the largest plants for all drives, and indications point to their even wider adoption in the future owing to their great saving in power and increase in range of application. Conservation of energy is one of the outstanding problems of the day, and the use of ball bearings is one method of attaining this end.

In a plant of the size such as will be established at Leaside, when a large amount of money is involved, the efficiency of ball bearings must be positively proved and demonstrated because it is possible to purchase similar equipment of plain ring-oiled bearings at considerably less cost. The savings in power and lubrication etc. are very high for ball bearing, and warrant this extra expenditure.

The S K F bearings have been installed in several of the larger Canadian plants, including the Canadian Westinghouse Co., Duncan Lithographing Co., and the T. Eaton Co., all of Hamilton. Also the Consumers Cordage Co., Montreal, the Howard Smith Paper Co., Willards Ltd., and the Laura Secord Candy Works, Toronto, all these being complete installations, in addition to many others.

The LONG Patent Steam Trap

Automatically drains jacket kettles, separators and steam mains. Nine hundred to 1,500 feet of one-inch pipe isn't beyond its ability. Also used with splendid success in drying room systems.

Only One Movable Part

Works against 1 and 200 pounds of pressure—no possibility of freezing. Has two outlets so it can be installed in any position.

Circular gives full particulars.

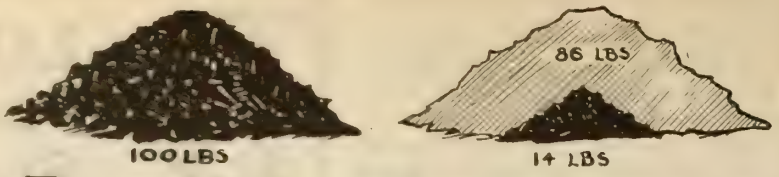
Study The Piles



Seven Times the Power for the Same Coal

The first pile represents coal used making steam to feed boiler using direct steam pump.

The black part of the second pile shows the relative amount of coal necessary to do the work with a Cole Return Trap.

In other words, you get seven times the power for the same coal—or 86% of the fuel saved.

If you want further proof get our latest folder on boiler feeding—No. 9.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 24 & 26 SOUTH ST. NEW YORK U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not [illegible] will cause a greater friction in the bearings a great [illegible] will occur. You will need to fire the boiler more often because the engine will be harder to run. In [illegible] you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers [illegible] Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

KINDLY MENTION THIS PAPER WHEN WRITING TO ADVERTISER.

THE VISCOSITY OF OIL

By M. E.

One of the most used methods of expressing the viscosity of oil is in the terms of the Engler Scale. Degrees Engler means simply the ratio of the time it takes a given quantity of an oil to flow through a standard orifice as compared with the time it would take the same volume of water to flow through. Oil is usually sold, however, on the basis of its specific gravity (generally measured in degrees Baume) and its heat value and moisture content. It is usually assumed that the heavier an oil is in degrees Baume the more viscous it is, but that is not always strictly true. It is not to be regretted, that oil is not specified in terms of specific gravity instead of in degrees Baume, because in any calculations involving the weight of the oil per gallon or per barrel, it is necessary to refer back to specific gravity. Further, the heaviest oil that can be designated on the Baume scale for liquids lighter than water is 10 deg. B. or unit specific gravity. Oils are now being used of 10 and 12 deg. B., and, no doubt, still heavier oils will be used, which will call for two different Baume scales and cause confusion.

Craft of the Hammersmith is the title of an illustrated booklet issued by the Canada Foundries & Forgings, Ltd., of Welland, Ont. The booklet illustrates by means of excellent photographic reproductions the various phases of the operations performed in the production of marine forgings at the Canada Forge plant and also views of a few typical forgings made by the company. The booklet is gotten up in an artistic manner and shows the marked development which the company has made, in this particular line, during recent years.

Letting You Into A Secret

THEY were talking about things in general — Jones and Brown. But it was easily seen by Jones that Brown talked with a positiveness and definiteness lacking in himself. Brown evidently had real knowledge about things and this gave him an assurance lacking in Jones. Jones found himself talking in generalities, and he had the sense to know that what he had to say wasn't very convincing. In the end he spoke up. "Brown, tell me, where do you get your information? You talk like one who knows. You use facts to fortify your opinions, and you seem to have a wealth of information about things Canadian. What's the secret of your greater confidence and knowledge?"

And Brown said: "I'll tell you, Jones, how I have strengthened myself in confidence and knowledge, as you put it. I read my newspaper in a new way now, and I make it a point to know a good deal about Canada, the land of my birth, residence and affection.

"For years—until I was forty—I read newspapers, as many others do—pretty thoroughly. I read about accidents, and meetings and fires, and everything else. One day I woke up,—was awakening up, to tell the truth—to discover that I was just frittering away time when I read everything.—Then I determined to concentrate my interest on matters Canadian—the things about Canada that really matter.

"I wanted direction. I needed a focal point, as it were. What should be skipped, and what should be read closely? I was floundering. I am not much of a politician, and I abominate party politics. I wanted to see things fairly.

"Then one day I made the acquaintance of THE FINANCIAL POST. It seemed to me to give me the direction I needed. I found it was sifting things for me, and giving current affairs their right proportioning. At any rate, it was a new kind of newspaper to me, and I read it with zest.

"I am a business man, and business in its larger aspects is the special field of THE FINANCIAL POST. I found the paper written in a readable way, and that it has a breadth of interest pleasing to me. So I subscribed for THE POST, and every Saturday and over the week-end this paper is pretty thoroughly ready by me.

"I find that the reading of this paper helps me get out of my daily newspaper the meat in it. As a matter of fact, I read my daily newspaper and other papers with a new and informed interest which makes my reading a profitable thing.

"I read somewhere that an hour a day spent on any subject would make a man master of that subject in 10 years. Well, I do not know that I am seeking to be a master of Canadian affairs, but I do know that for the past two years or so I have been having a new joy in life. I am really trying to know my Canada.

"I clip a good deal, and my scrap-book on Canada is a treasure house for me, I collate the material I put in that book, and whenever I want to read up any particular subject, I have before me, gathered up, a surprising amount of material obtained from many sources.

"I take luncheon at the Club daily. There are eight of us who gather daily at the same table. One is a wholesaler, another is a banker, another a publisher, another a manufacturer, another a manufacturers' agent—and so on. We have a representative gathering.

"We talk about many things, and about Canada most of all. I take great satisfaction from the knowledge that I am able to hold up my end of the conversation. To tell you the truth, it is this reputation that spurs me on to keep myself brushed up all the time. I own up, also, to practising a little subtlety. I guide the conversation in the direction of a subject that I am well informed on, and then I bide my time, letting others wrestle with it until they have told all they know. Then is my chance, and I am able to say something useful to a company that is attentive.

"Jones, if you want to improve the quality of your information, read purposefully, objectively. Cut out the reading of everything under the sun. You are a business man, the same as I am. Why not read definitely along the line of business? You will find it a most pleasurable kind of reading, and you'll find that you will acquire the sifting mind which will enable you to pass over a lot of stuff of no value to you, and seize on material of real value.

"I recommend THE FINANCIAL POST as a paper that will give your reading direction. It has helped me much, and I believe will help you. At any rate, it is easy to try it out."

IF JONES wants to try out THE FINANCIAL POST he can have it go to him by mail for four months for a dollar bill. One thing that ought to impress and please Jones is that THE POST is not a one-man paper. It is produced by many men, each a surpassingly well-informed man on the subject he writes. One man writes on matters pertaining to agriculture, another on the iron and steel industry, another on the food problems and milling and cereal subjects, another on insurance, another on textiles, and so on. The special contributed articles which are a regular feature of THE POST are by authorities or by men of position. Besides which, THE POST surveys many fields of interest, and this survey is world-wide. It is a meatful paper, in very truth, and assures those who read it regularly an amount, kind and quality of reading not commonly found in a single newspaper. If you would make your daily reading take on a new interest and value, we suggest that you should sign and forward the coupon opposite.

III IMPORTANT THINGS

TO CONSIDER ABOUT A SEPARATOR.

I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

GRATON & KNIGHT

Standardized Series

LEATHER BELTING

Tanned by us for belting use

GRATON AND KNIGHT

Holding the Line

YOU honor the Turbine as a Field Marshal, the Engine and the Generator as Generals. But, how about Private Belt, without shoulder straps or collar emblems, grimly holding the line? Too often you give him consideration only when, under cruel strain, he breaks.

The great need is to fill the line with those Privates that stand the strain better than others. A guiding rule, easy to remember, is that the demand for Graton & Knight Standardized Series Leather Belting is greater than that for any other belting in the world. It started from nothing and has grown steadily and naturally.

There are many technical reasons for this preference, but the big reason is *not* technical. It is simply repeated experience: Mr. A. buys a Graton & Knight Belt and observes that it gives all-round service and long wear. He doesn't always know whether to credit these qualities to the materials or the construction. What he does know is that the belt *works right*—and that is enough.

In our book, "Standardized Leather Belting," we explain scientifically why Graton & Knight Standardized Leather Belts are enlisted to hold the power line in so preponderant a number of American factories. Write for a copy.

The Story of War Under The Earth

THE German sappers had discovered and broken into a Canadian tunnel. They had planted a machine gun at their end and sent a shower of bullets down the dark, narrow passage whenever the Canadians made any effort to enter their underground galleries. The story of how two Canadians nailed steel snipers' shields to the front of a push cart and shoved it ahead of them up to the very teeth of the gun, and how they dropped a can of deadly explosive, hopped on to the cart, and let it coast back down the tunnel, while bullets rattled on the shield like hail and, finally, how the explosive blew up the machine gun and its crew and blocked the passage again—this remarkable story is told by Lieut. C. W. Tilbrook (who was one of the two) in the course of an article, "An Underground Tank," in October MACLEAN'S.

Recently a Toronto newspaper declared editorially that the public was tiring of war books and war stories because of the sameness of them. The newspaper was right. But the public literally devours any story of the war that is new. The series of articles that Lieut. Tilbrook has done for MACLEAN'S has been read with an astonishing amount of interest *because they are different from anything that the public has yet read.* Warfare in the tunnels is a terrible business—grim, silent, cruel. It is a strangely technical phase of warfare and the "sappers" go about their business with queer instruments that might have figured in a Jules Verne phantasy. To read of underground fighting, as Lieut. Tilbrook tells of it, is to get a vision of a new kind of war altogether—something gripping, fearsome and mystifying.

"An Underground Tank," is the best of his series. But, after all, it is only one feature in a long array that makes the October issue of MACLEAN'S one of unparalleled interest.

A STRANGE CHANGE IN WOMAN'S WORLD. By Agnes C. Laut.
The new status of women, arising out of the war, is treated in the powerful style of this famous writer, who came from the Canadian West. It introduces a new thought.

CONSCRIPTION AFTER THE WAR. By Brigadier-General A. C. Critchley.
A young Canadian who rose from Lieutenant to General in three years and originated the "Critchley Method" of military training, tells what he thinks about the need for compulsory service after the war.

THE LIFE OF MARY PICKFORD, by Arthur Stringer.
The second of a series of articles on Canada's most famous woman. No expense has been spared to produce the beautiful illustrations specially posed for the photographs.

THE FOUR FACTIONS AT OTTAWA. By J. K. Munro.
That the House will split into four, more or less, distinct groups is the guess of the author, a trained political observer. He outlines the reasons humorously, pungently and impartially. It is a political article on new lines and will be found refreshing.

BONEHEAD BILL—Another Service Poem.
Robert W. Service, most popular of poets, sends all his war verse to MACLEAN'S. In "Bonehead Bill" he depicts the grief of a soldier for his fallen foe.

THE EVENTS OF A MAD WORLD
are summed up in the "Review of Reviews" which gives reprints of the best articles from the magazines of the world. All the best and most important articles are selected—five dollars' worth for twenty cents!

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction*. Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs*. Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

Wanted—

Engineers to Contribute to Power House

THIS is a practical paper for practical engineers. It is an educational medium and out to help its readers. It is a technical school and a social meeting place combined. It is first, last and all the time an engineer's paper.

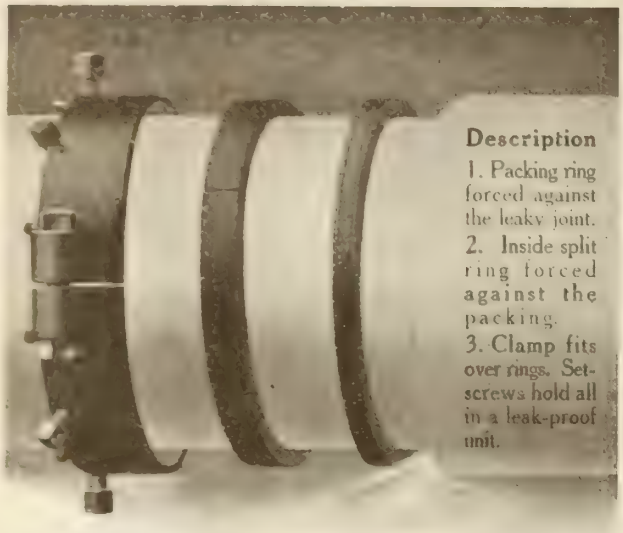
If you should meet two or three or a dozen of your brother engineers you would swap ideas—you'd tell of some idea you had worked out in your plant. Others would describe some pet schemes they had devised. And so you would be mutually benefited.

Why not make Power House your monthly meeting place? Why not describe in this paper some kink or scheme you have worked out and found successful? We will pay you for it and you, in turn, will be multiplying the usefulness of your idea five thousand fold!

Never mind polishing up your letters—just give us the idea; that's the main thing. Never mind how crude your pencil sketch may be. We have draughtsmen who will finish up your drawings so they may be reproduced.

Try this idea a time or two and see how much satisfaction you'll get out of it. Start the ball a-rolling and thus help other engineers, yourself and your paper.

POWER HOUSE, 143-153 University Avenue, Toronto, Ont.



Description
1. Packing ring forced against the leaky joint.
2. Inside split ring forced against the packing.
3. Clamp fits over rings. Set-screws hold all in a leak-proof unit.

You Can Stop That Leak

—And stop it permanently—with a Simplex Pipe-Joint Clamp.

It does not make much difference how big the opening may be—provided, of course, it is not beyond repair. Nor does it matter a great deal what is in the pipe—water, steam, gas, air, oil, ammonia, brine, etc.—the leak will be stopped absolutely.

And as long as the Yarway is left in place that joint will remain tight.

The principle of the Yarway Pipe-Joint Clamp (formerly Simplex) is very simple. There are but three parts, as shown above—one packing and two iron rings.

Any workman can make the attachment without difficulty in a few minutes.

As an example of the way in which this serviceable clamp makes good, read what one user says:

> "The fact that from the date of its installation, we have not realized that there is a steam joint at the point where placed, is sufficient evidence that it fills the bill."

Try a Yarway for 30 days subject to return if not satisfactory in every way. Write to-day stating size of line.

IT tells how to save coal

A real help sent free to Plant Owners & Operators

WHAT question could be more pressing to those interested in a power plant or factory than that of next winter's coal supply? Particularly now, when the government has added further emphasis to the situation by its move to cut fuel waste through a plant questionnaire.

The booklet offered above, "*Fuel Waste in the Power Plant,*" is designed to be of help in assuring coal supply, by suggesting, as it does, many simple and effective measures for the reduction of preventable waste, in the burning of coal and in the use of steam for power, heating or processing.

The pamphlet does not attempt to suggest radical and expensive equipment additions. It discusses plants as they are and indicates a score of individually small but collectively large losses commonly overlooked in the operation of the power plant and factory.

A reading of this pamphlet will be reassuring to manufacturers or other plant interests in showing how inexpensively and often how readily, waste power, heat losses, wear and tear and frictional losses can be reduced. Its timeliness speaks for itself.

For sixty years we have been developing and advocating the use of coal and power saving materials and feel that we can serve the common good by sharing our experience with plant executives and engineers — particularly now when coal and power saving mean so much to everyone.

We will be glad to forward you a copy of "*Fuel Waste in the Power Plant,*" if you will write our nearest branch.

A world crisis has lifted plant efficiency out of the commercial up into the great heights of National Conservation. And it is very gratifying to be able to contribute the sum total of our own small efforts over these past twenty-five years to help bring about a greater measure of fuel saving.

Write any of the offices listed here for your copy of this new booklet—use coupon below. To ensure proper directing in the mails, give some individual's name—your own, your master mechanic's or your engineer's.

If you want to meet a Johns-Manville man in person you can so indicate on the coupon in the circle.

WILLIAMS' Improved "Vulcan" Chain Pipe Wrench

CERTIFIED O.K.

A GOOD workman is known by his tools—a tradesman by his stock. You, like the great majority of others, want only the **best** in pipe tools—that means Williams' "Vulcan" and "Agrippa"—for only in them can be obtained "certified" chains. Each and every flat-link chain is regularly "proof-tested" in a standard tension machine; it is then stamped "O" on the drop-forged swinging link and to it is attached a gray leaden seal bearing our trade-mark —the proof of quality—to certify that it has passed our standardized tests.

We certify—you verify.

Ask for booklet—it's free!

What is the Best "Light Policy?"

THOUSANDS of manufacturers have asked this question and have found the answer to be—

A light that increases production for the same labor cost.

A light that promotes greater accuracy in workmanship, and thus reduces spoilage and accident hazard.

A light that avoids unnecessary eyestrain and bodily fatigue, and makes surroundings more cheerful, promotes neatness and sanitation, and renders superintendence more effective.

A light that reduces current and maintenance cost.

They have found such a light in

LACO NITRO LAMPS

The reduction of current and maintenance costs by Laco Nitro Lamps is due to two prime reasons: Their high candle power requires fewer lamps, and their long life reduces replacements. Official tests have proved that Laco Lamps burn 30 to 50% less current and last 25 to 50% longer than any other make.

There are no "official" statistics of their conservation of man-power, material, time, and general efficiency—but individual records from prominent plants all over the country prove beyond question their results in this direction. If, by the most conservative reckoning, they save 5 minutes of a workman's time per 8-hour day, here is a saving of 1% on wages expenditure. Surely these are facts enough to show that

The Laco Light Policy Pays Handsome Dividends

Call our lighting experts into consultation to-day, and let us devise the best system to meet your needs. Drop us a line for interesting pamphlets and data.

Thrift

Thrift means conservation, and in the Power Plant applies particularly to valve equipment. Where

LUNKENHEIMER REGRINDING VALVES

are used, thrift is assured because these valves can easily be repaired—the seating surfaces being regrindable and all parts interchangeable.

Users should profit by their installation, regrinding the seating surfaces or replacing a part when necessary, in preference to discarding the entire device.

To repair means to conserve. To conserve means to economize. To economize is to practice THRIFT, which is essential to our success in the war.

MUELLER

E5010 For Water

Reducing and Regulating Valves

Before you install your valve, be absolutely sure on these three points.

1. **The right kind** of valve is the one that is adapted to your particular service. No one type will answer all purposes. Different service and at times different conditions in the same kind of service necessitates different types of valves.

2. **The right size** of valve is the size that will make the proper reduction and regulation and has a wide enough seat opening to prevent obstruction and cutting out of the seat. *A general fault is using a valve that is too large.* Ordinarily they should be smaller than the pipe to which they are attached.

3. **Proper assembling** means that valves should have working parts suitable to service, and diaphragms and springs suitable to pressure range.

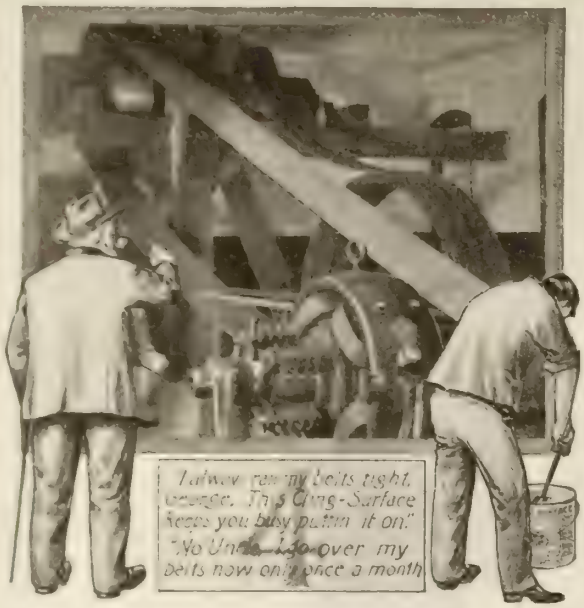
Don't guess. Consult us. When valves are installed under MUELLER supervision, we fully warrant them to perform the service for which we recommend them.

We make valves for water, steam, gas, air, oil and ammonia. There is a stock valve in our catalog that will meet your needs. If you have a specially intricate problem to solve, our experts are at your command.

H. MUELLER MFG. CO., LIMITED

SARNIA, CANADA

MUELLER



I always run my belts tight, George. This Cling-Surface keeps you busy puttin it on."
"No Uncle, I go over my belts now only once a month

WE stood and watched him.

Above and on all sides of us the belts were moving: large and small, vertical and horizontal, quarter-turn and cross belts; each moving swiftly, silently.

There seemed to be thousands! And the Superintendent had told us that this ONE MAN took care of them all! We stood and watched him.

He carried a pail, and a stick wrapped at one end with a cloth bandage. Dipping this into the pail he carefully wiped the excess off upon the edge and laid the stick against the face of a moving belt. As he worked it back and forth we saw a light stain appearing on the pulley face. He was watching this also, for apparently satisfied, he stopped the treatment and went on to the next belt.

So that was all? A dip, a wipe and a few passes back and forth across the belt face? But how long would it last?

"That belt," said the Superintendent, "is now in such fine condition that it will not require any more CLING-SURFACE for a month. It is quite pliable, waterproof and practically oilproof, and what is more important still, it never slips even under the peak load. You see it is running very slack—we haven't had to take it up for three years.

"Before I had the shop use CLING-SURFACE we ran all our belts tight, and were having trouble every day. It kept four men busy just taking up belts, and applying belt dressing, but now this one man with the new semi-liquid CLING-SURFACE treats them all."

That is the NEW way to apply the NEW semi-liquid "easy-to-use" CLING-SURFACE. It requires no heating in ordinary temperatures. It results in a money saving more than covering the cost of the CLING-SURFACE required.

The plan 10,000 firms have found successful will interest you. Let us send it free, with any special service your conditions may require.

Remember, use CLING-SURFACE and you won't need belt dressings.

"JOHN CRANE" FLEXIBLE METALLIC PACKING

is applicable to gate valves, hand valves, all kinds of plungers and rods, condenser tubes, and wherever packing is needed. It is the only really UNIVERSAL material made which packs with equal leaklessness and frictionlessness; steam, water, ammonia, gas, gasoline, acids, crude oil, distillates, vapors, etc.

Can you beat it? No. Can you equal it? No.

YOU CAN CUT IT WITH A KNIFE

just like flax. It is as flexible as flax; more durable; tighter; doesn't wear the rod a bit, but improves and gives the rod a high polish; frictionless as a babbitted bearing because "John Crane" itself is made of thin babbitt foil wound spirally from the center with the highest grade of lubricant sandwiched between the hundreds of layers.

Can you beat it? No. Can you equal it? No.

Different from the shredded, braided, twisted, granulated, shot, poured and segmental types. It is the only packing of its kind on the market. Every ambitious engineer should know all about it.

Any engineer with new rods can get this material on approval, if he speaks, now. We'll demonstrate at our own risk on any new plunger, new pump rod, new accumulator, new press, etc. Write for Bulletin No. 1 which tells all.

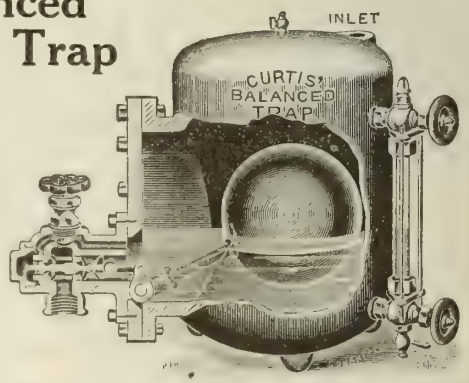
Balanced Steam Trap



This trap is often used as a waterline trap on large plants where there is need to balance any particular circulation to prevent snapping and cracking in pipes and radiators.

This Trap Has These Points of Difference and Superiority

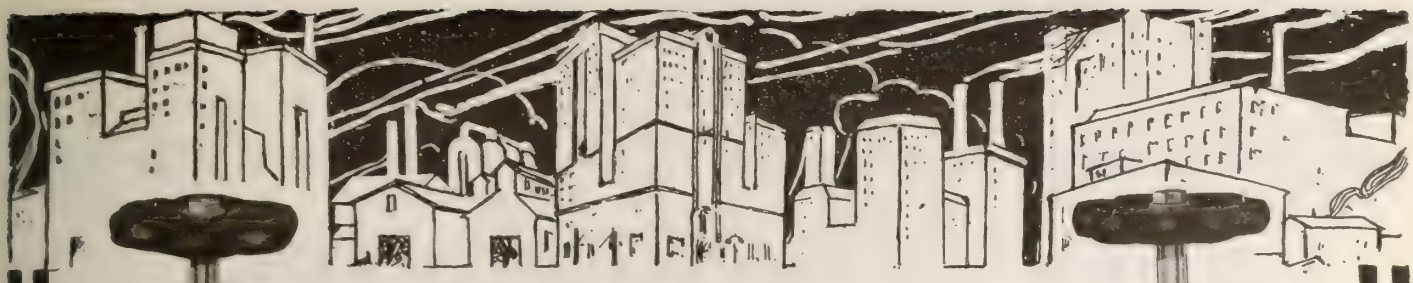
1 A perfectly balanced valve.
2 An absolutely frictionless valve.
3—The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4—The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5—Each trap will operate perfectly on pressure varying from one to 250 lbs.

The great merit of this trap, its simplicity, its dependability and serviceability make it well worth being better acquainted with. Send for special printed matter describing it and giving prices. Address the Manufacturers.

JULIAN D'ESTE COMPANY

Main Office, 26 Canal St., Boston, Mass.

Agencies: 216 Fulton St., New York City; 174 N. Market St., Chicago, Ill.



Jenkins Bros.

Valves

EVEN an apparently insignificant hiss of steam past a poorly seating valve will cause a material fuel loss per year. Multiply this figure by the number of valves in the average plant and the loss becomes appalling.

Dependable valve service is essential—more so now than ever before in view of the great scarcity of fuel.

No matter what the type of building or plant, the best valve service is necessary. Installing good valves at the start saves repair and replacement charges and the labor costs of re-installations later.

Whether you require valves for industrial plants, public or private buildings, **Jenkins Bros.' Valves** should be your choice. You can rely upon them under conditions where other valves would fail.

They will hold absolutely tight under steam, water, air and gas pressure for very long periods of service without attention. The design is heavier than the usual commercial standard pattern of other makes, enabling us to guarantee them for 175-lb. steam or 250-lb. water-working pressure. All are fitted with renewable Jenkins discs made of a softer composition than the metal and which will seat perfectly tight in spite of inequalities or rough spots in the metal surfaces. When worn the discs may be replaced at trifling cost and the valves will become as tight as when new. The composition of the discs is varied to suit the particular requirements of each class of service.

Furnished in brass or iron body, in globe, angle, cross, check, Y or blow-off, hose whistle and other patterns.

GREEN'S ECONOMISERS

save one or more cars out of ten.

THE use of Economisers is more important now than ever before and all new plants should be equipped with them, also all old plants that are engaged in essential work.

The others will have to wait until after the war.

Some of the reasons for the importance of Economisers now are:

FIRST—They save 10 to 15 per cent. of the coal that would be needed if the boilers were operated without them.

SECOND—They can be used to increase the present boiler capacity or to get greater capacity out of new boiler equipment.

THIRD—The coal saving releases cars and railroad facilities which are very important under present conditions.

FOURTH—This saving also helps in overcoming the shortage of miners caused by enlistment or drafting.

FIFTH—If used to increase the boiler capacity this releases boilermakers and steel that can be used to make boilers for marine service and other important uses.

The complete list of reasons is too long to be given in detail. Our Engineers will be glad to give you others and also explain the application of Economisers to your plant.

A new Economiser Catalog will be ready soon. May we put your name on our mailing list now? Just fill in and send the coupon.

GARLOCK PACKING

FOR EVERY PURPOSE

Thirty-one years ago we began to manufacture packing and during that time we have steadily insisted upon the best of everything that enters into our product—design, material, workmanship. Constant effort has been directed toward improving and perfecting our packings to keep pace with the wonderful progress that has been made in the development of modern machinery.

Our factories, devoted exclusively to the manufacture of our packings, are the largest, most modern and best equipped in the world, and the locations of our numerous branch factories and stores are such as to afford the greatest advantage in serving our customers promptly.

We are Exclusive Packing Manufacturers—We Make Nothing Else

POTATO SCALE POWDER

A Simple, Inexpensive Means of Saving Fuel

Canada will face a serious fuel shortage next winter. Every pound of coal should be conserved—right now. A little POTATO SCALE POWDER in the feed water of your boilers each day will save many tons of coal for Canada in the course of a few months. POTATO SCALE POWDER removes old scale from the boilers and prevents any new scale formations, thus your boilers are able to do maximum duty with a minimum amount of fuel. No pitting, foaming or other troubles, due to impurities in feed water, where POTATO SCALE POWDER is used.

Made to suit feed water conditions and contains nothing that will cause the slightest injury to boiler metal or fittings.

Large power plants in Canada and United States are constant users of POTATO SCALE POWDER. Positively guaranteed. Try a barrel and watch the result.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID,
Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D.,
Supt. Trades & Labour Branch

Battery of Figure 64 Units

The next time the president of your Company steps into the machine shop or power plant, speak to him about the tremendous oil waste charged against you as a formidable operating expense, but which you cannot prevent so long as you do without a Bowser Oil Storage System.

Explain the reason for so great a waste. Definitely mention seepage, evaporation, absorption, countless spills and drips.

Show him the oil-soaked floor—a fire menace every hour of the day and night.

Finally hand him the Bowser Book on Oil Storage Equipment. If he doesn't thank you on the instant, he will a short time later when he discovers that Bowser Equipment has cut the oil bill in half or more.

Write to-day for the Bowser Book and Full Particulars of Bowser Engineering Consultation Service.

JEFFERSON UNIONS

You Can Get Every One of These Useful Types—Ask Your Jobber About Them

There are dozens of different style Jeffersons—in fact, no matter what sort of a job of pipe work you are doing there is one that will simplify the making of the connection immensely and in every style union are embodied the important Jefferson patent features which make it **the** logical pipe union for mine work.

For instance:

The Ground Ball Seat—

The joints between the union parts—to insure a perfect fit no matter how they are set up—are ground. And they are ground in pairs—that is, the two pieces which seat on each other are mated from the time they are cast till they are delivered to you; they are never separated.

The Brass Seat Ring—

Another Jefferson feature is in the brass seat ring which is a **piece of brass tubing forced into a recess back away from the runway and contents of the pipe.** This serves to prevent corrosion at the joint.

If your jobber can't supply you, write us for name of our dealer in your territory.

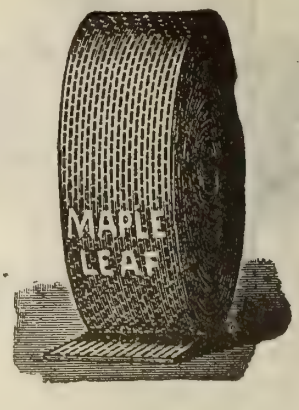
Dominion Belting Company, Limited
Hamilton, Canada

Sole manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



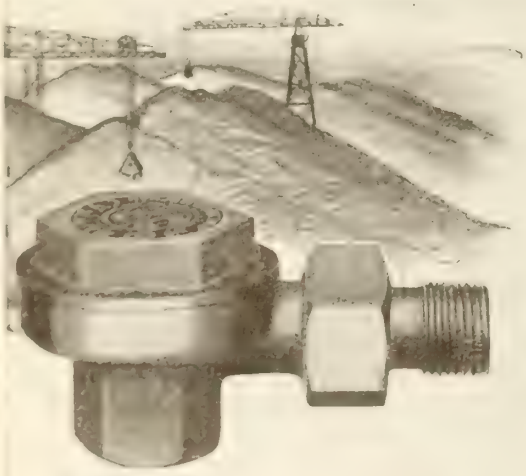
"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

DOMINION BELTING CO. Ltd., Hamilton, Canada-Quebec Branch: 51 Duluth Bldg., Montreal



Save Your Part of the 30,000,000 Tons

Canada will use about thirty million tons of coal during the coming winter—that is, if we can get it. That which is obtained must be made to do its work extra well. You can help in two ways—burn the coal most efficiently; tell your employer to investigate

The DUNHAM HEATING SERVICE

—a service that has brought about some remarkable savings of fuel in heating systems. Many of the largest buildings in Canada use the Dunham Radiator Trap—one of the fundamentals of the Dunham Heating Service!

Full information sent promptly on request.

The Dunham Radiator Trap
—the secret of heating efficiency

Radiators knock and pound and waste steam when they are choked up with air and water. By automatically removing these coal-wasters, the Dunham Radiator Trap gives the steam a chance to circulate easily through the radiators. No jet water at vacuum pump is required.

Speed up with Electric Power

C-G-E Motors and Control increase production and reduce maintenance

Here are some of the ways in which modern industry has been speeded up by putting electric power to work in the right place.

Metal mines have boosted output to meet world-wide demands. All tonnage records have been smashed in the steel industry. Greater automobile output has lowered prices and given better road transportation. More and better cloth has been produced at lower power costs. Contractors find electric drive faster, more elastic and cheaper than any other for hoists, pumps, concrete mixers, cableways and other equipment.

On the left is shown a 350 h.p., C.G.E. induction motor direct connected to a line shaft driving beating engines in a pulp mill. The illustration on the right shows two 50 h.p., C.E.G. induction motors belted to sluice pumps in a gold mill.

Any problem involving the use of power can be simplified by the application of electricity. The Canadian General Electric Company is well equipped to lend valuable assistance in working out such problems and is glad to co-operate with contractors, manufacturers and engineers in every possible way.

C-G-E MOTOR DRIVE

NOTICE

TO

Stationary and Hoisting Engineers

Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

HON. F. G. MACDIARMID, Minister of Public Works and Highways.
W. C. McGHIE, Chairman of Board.
W. A. RIDDELL, M. A., PH. D., Superintendent, Trades & Labour Branch.

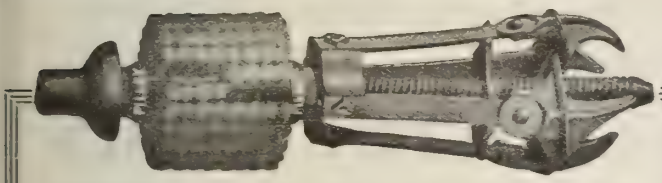
A System That Saves Many Bright Dollars!

Every dollar saved to-day is a dollar added to the nation's resources at a time when the nation needs its resources most.

Are you getting condensation back to the boilers HOT? If not you are wasting valuable heat units—heat units that represent actual dollars in coal losses. What you require is the **Morehead Back-to-Boiler System** in your plant. It delivers back to the boiler pure HOT condensation unfailingly, completely, wastelessly, and automatically.

Furthermore, the "Morehead System" saves the boilers and saves much labor; gives relief from pump troubles, maintains equally controlled **uniform** temperature in your plant, and in other ways makes for better and more economical steam service.

Canadian Morehead Mfg. Company, Limited
Woodstock, Ontario



Looks like a good tool and it's just a little better than it looks. Adopted as standard by thousands of engineers who know from experience that it always gets results.

Pilleys Combination Flue Brush and Scraper

is adjustable to the tube—scrapes and brushes thoroughly in one operation. Guaranteed against defective materials and that wires will not pull out or lay over. For sale by leading Canadian jobbers.

The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH

Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.

Nut with Nut-Guards

ELECTRICAL SAFETY AND ECONOMY

ECONOMY
Renewable
FUSES

Cut Annual Fuse Maintenance Cost 80%

Economy "Drop Out" Renewal Links are responsible for this saving.
A "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.
A sustained arc is impossible.
It's the work of a moment for even a novice to replace the link and renew the fuse.
First in its field—first in efficiency.
Order from your dealer.

SCANDINAVIA BELTING

Is a Good Belt for Dusty Places

In cement plants and brick plants where there is lots of dust, this belt is producing results that are very satisfactory for the mill operators.

You know how wearing grit is on a belt, and you want a belt that will not come apart when only partly worn through.

"Scandinavia" is this kind of a belt—there are no plies to come apart—it is solid woven. We have seen these belts still giving good service when the thickness was half worn through, and on the pulley side of the belt there were no frayed ends—the surface of the belt was smooth.

Mr. Plant Manager, you know what this means. If you require a belt for operating in a dusty place, let us ship you one, please. It will be a pleasure to us both.

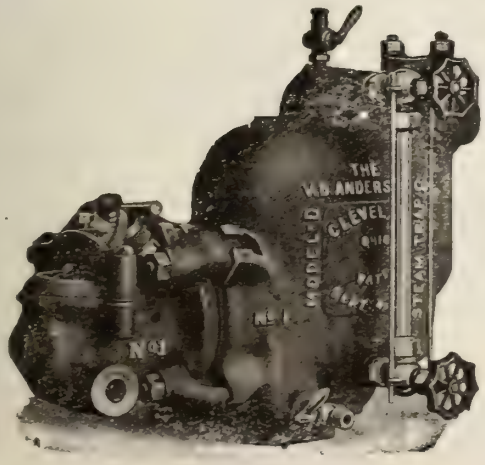
FEDERAL ENGINEERING CO., LIMITED,
172 John Street, Toronto

NOTE—Do not use "bar" or "stick" belt dressing on textile belts.

The Trap that Stays Tight

It means something to you in time, labor and expense to have a trap in your steam-room that will stay tight from the day you put it in. This dependability under high and low pressure is found in the

Anderson Model "D" Steam Trap



Features of this trap include simplicity of design, quick action and large capacity. It is operated by a counterbalanced LAKE SUPERIOR COPPER FLOAT. Has large air valve that will not wire draw and is always under deep water seal.

A self-contained strainer, an outside gauge glass, a self-contained by-pass and complete accessibility to all parts are other outstanding features of the Anderson Model "D" Steam Trap.

If you are troubled with condensation or any boiler room trouble, get in touch with us and secure our co-operation.

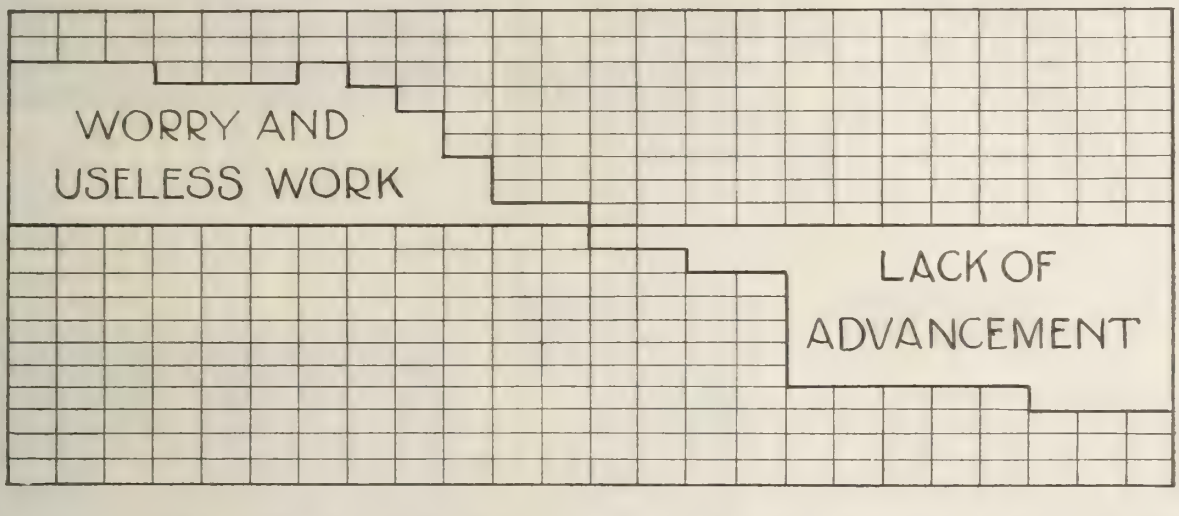
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary,

Canadian Association of Stationary Engineers

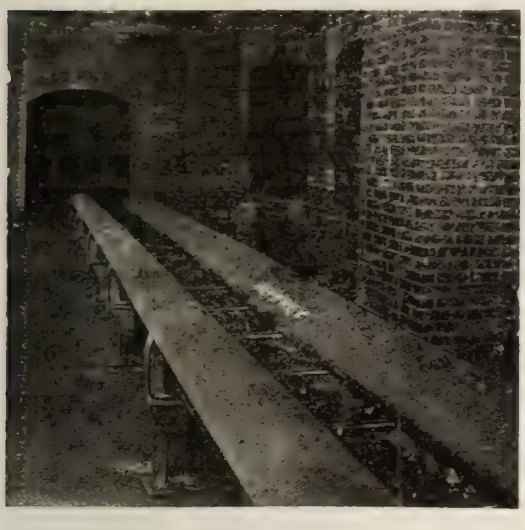
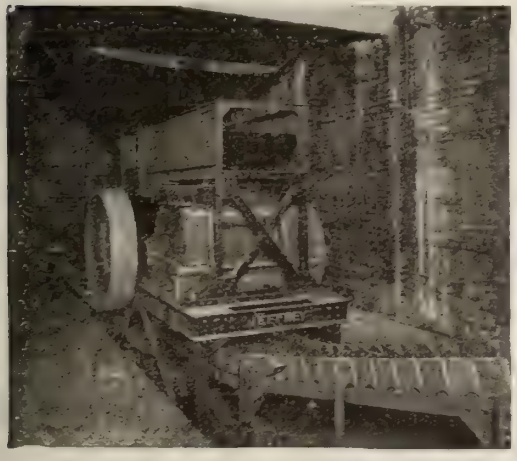
165 ft. upper run of Jeffrey Carrier over coal and ashes storage bins of the Transue Williams Steel Forging Power Plant, Alliance, Ohio. 50 tons of Crushed Coal per hour is dumped by the traveling tripper shown.



Another view of the Jeffrey Carrier shown above. Note the curved steel skirt boards, which not only form a continuous trough for loading the conveyer, but serve as a protection for the Chain against dirt and grit.



Jeffrey 30-in. x 30-in. Single Roll Crusher installed with Coal and Ashes Handling System at this plant. This Crusher in one operation reduces Run-of-Mine or Lump Coal to the proper size for maximum heat efficiency in stokers.

First of All
Character

Defined by Webster, CHARACTER means DISTINCTIVE FEATURES—and all things that have Character abound in Quality.

The Distinctive Features of

THE JEFFREY
IMPROVED CARRIER

have been gained from the knowledge of nearly 20 years of actual experience in the installation of successful pivoted bucket outfits.

"Reliability" and "Durability"

are the first considerations in its design and construction—absolute reliability under all conditions of service—coupled with that material strength, quality and hardness of wearing parts throughout, which insures long and satisfactory service.

Write for our new Bulletin No. 237-4. It fully describes the Jeffrey Carrier and its many points of refinement, and pictures interesting installations.

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CATALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.**

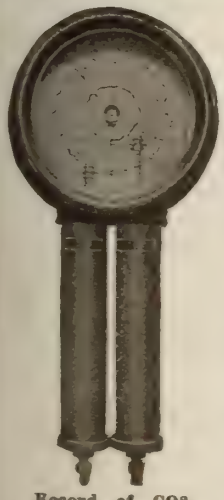
MACGOVERN & COMPANY, Inc.

114 Liberty St., New York City

UEHLING WASTE METER

COMBINED

CO_2 AND TEMPERATURE RECORDER

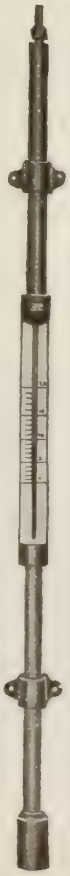


Record of CO2 and stack temperature on one chart.

Does your fireman know how much fuel he is wasting? Do you know?

The **Uehling CO_2 Recorder** makes a complete 24 hr. record of your combustion efficiency and the **CO2 indicator at the Boiler Front** holds the fireman responsible.

Get more **Steam** per pound of **Coal** and reduce your annual fuel consumption.



CO2 Indicator for Boiler Front

Let us know the number and size of your boilers and coal consumed per year, upon receipt of which information we will be glad to send you full particulars.

Let us hear from you. We are pioneers in the manufacture of Indicators and Recorders for Power Plant purposes.

Send for our Bulletin No. 110.

Uehling Instrument Company

2008 Empire Building **New York City**

INGLIS BOILERS

Boilers for all Services

Inglis boilers are used in Power Houses in every part of Canada. They have set the standard for years in efficiency, and are noted for their long service. Strongly built—require minimum repairs.

Sole Canadian makers of Erie City Water Tube Boilers, Vertical and Horizontal.

Write for prices and specifications, or have our representative call upon you.

If there's scale on your boiler tubes---

It lies within your power to greatly Reduce Fuel Consumption

Examine your boilers now and prepare for the coming winter and an acute fuel shortage.

Get a Dean Boiler Tube Cleaner and put it to work at once. **It will reduce coal bills from 9% to 35%** depending upon the amount of scale in your boiler tubes.

The secret of the success of the Dean lies in its vibratory action—a controlled and localized vibration loosens the scale in large chunks. In a return tubular boiler the loosened scale falls to the bottom of the boiler. In a water tube boiler the pieces are ejected from the tube by the cleaner exhaust.

The Dean cleans boiler tubes clean. It gets all the scale. The Dean, because of its few and simple parts, takes out scale faster and more thoroughly than any other known methods; and its sturdy simplicity means long life, low upkeep cost and ease of operation.

Dean

Reg. U.S. Pat. Off.

Boiler Tube Cleaner

Mr. Smith

chief engineer of Macdonald Mfg. Co., Toronto, Canada, manufacturers of biscuit boxes, paint cans, etc.,

Says---

"In five years we haven't had to want for power five minutes. Never any trouble. Horsepower developed (250).

He uses the "Dean"

Try the Dean Cleaner Free of Charge

Write a letter: "Send us a Dean on trial, with the understanding that we are under no obligation to purchase it," and state type of boilers and exact outside diameter of tubes.

The Wm. B. Pierce Company

153 Ellicott Street, Buffalo, N.Y.

BOILERS

FOR POWER AND HEATING PURPOSES

You will find Waterous Horizontal Return Tubular Boilers in the largest industrial and municipal power plants in the country. There are reasons for this. They are economical of fuel, carry a big reserve steam pressure for use in emergencies, can be used with hard and dirty water, and are readily cleaned and easily taken care of. They cost little new; their upkeep and maintenance expense is negligible.

Waterous Horizontal Return Tubular Boilers are built in all sizes from 40 inches by 10 feet to 72 inches by 18 feet. Most standard sizes are carried in stock. If we cannot supply you at once from our yards we can turn out your order for you in quick time. On the next boiler you need let us quote you prices and delivery.

Every Barrel of **BOICO** The Quick Remover and Positive Preventive of Boiler Scale

SAVES A PILE OF COAL

It's such a heartless job trying to keep a boiler clean with ordinary compounds that comparatively few are always wholly clean. Consequently a good deal more fuel than need be is turned up on the grates. We claim for Boico that it removes absolutely all scale; that it positively prevents further formation of scale; that it does not carry over in the steam; that it does not cause foaming or priming; that it does not injure packing or valves in the slightest. You do not pay for Boico if it fails.
Write for our trial offer.

Anti-Clinker Shell Bar Grates

save coal. For one thing they prevent clinker formation. Half this total surface is air space—and abundant air commands perfect combustion. Let us tell you more in detail.

CORRECT LUBRICATION OF VITAL IMPORTANCE

Success in milling, manufacturing or mining—success in almost every line—is largely dependent upon power. The power-plant is the heart of your works. Efficient power-plant operation depends upon correct lubrication more than upon any other one thing. Correct lubrication is assured by the use of Imperial Lubricants.

Good mechanical engineers know that by using Imperial Lubricants, more dependable, as well as more economical power, is secured. They know that by their use more years of service may be secured from power units, factory output increased and overhead costs decreased.

Good mechanical engineers know, too, that the price is not nearly so important as the quality of lubricants. They realize that poor lubricants are not cheap at any price. They know that our line gives more hours of lubrication, dollar for dollar, than any other and that power-plants can more easily be kept in perfect running order if our line is used. That is why good mechanical engineers are so ready to recommend Imperial Lubricants.

Our Lubrication Engineers will gladly assist your own engineer or mechanical superintendent to determine the most economical and efficient lubrication for your power-plant. Their services are free.

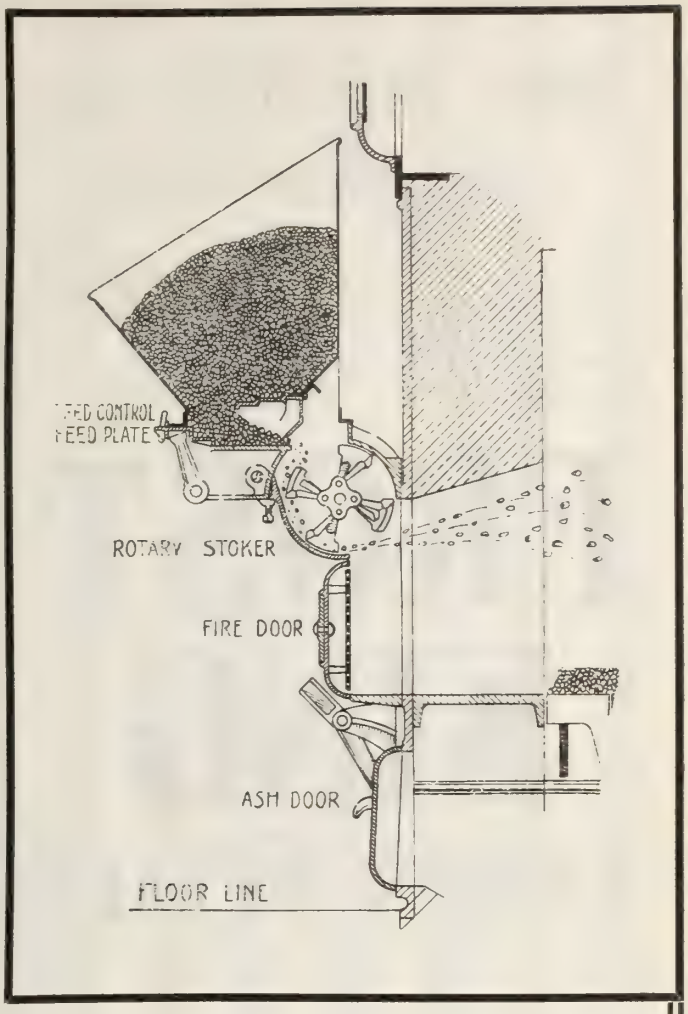
Not a pretty picture but—

It Solved the Coal Question for Another 10 Plants Last Month

And it freed 20 expert firemen for production work in the "profit-making" departments of these plants.

All because it shows the operating principles of the



Galt Sprinkler Stoker

and the logic of these principles appealed to the common-sense of the men who own the "20 plants" referred to in the caption of this advertisement.

Therefore will you please study this drawing.

Note the Rotary Stoker. In a light, continuous stream it automatically feeds to the furnace cheap anthracite dust to 3-in. lump. As it feeds, it so uniformly spreads the fuel as to give a level fire 3 to 4 inches thick.

Note the **closed** fire door. No in-rushing draft of cold air here to upset perfect combustion or to act as a drag on the efficiency of your boiler.

Also the Feed Control and Feed Plate. Not one part in contact with the furnace flame. No complicated mechanism that lump or low-grade fuels can clog.

The Galt Sprinkler Stoker operates with natural draft and with forced or induced draft equally well. It gives practically smokeless combustion.

Illustrated catalog tells how the Galt Stoker, with 10 to 20% less coal, makes more steam. Write for copy.

Coal Supply Not Equal to the Demand

The industrial plants of Canada and United States are demanding over 100 Million tons coal above the normal supply. Because of labor shortage and hauling facilities it will be impossible to increase the supply more than 50 per cent. The remaining gap of 50 million tons will have to be filled in by conservation in the industrial plants of Canada and United States.

No better means to help fill this gap can be found than in the use of

Coppus Turbo Blowers

You can burn anything in the shape of coal with the assistance of Coppus Turbo Blowers and make your boilers develop maximum capacity.

One power house superintendent said: **"We have got your blowers going and now we are burning dirt."**

You can easily run your boilers at 200 per cent. of rating. Increase their efficiency, reduce your fuel expense, help your country solve the fuel problem and save yourself a lot of needless expense by installing Coppus Turbo Blowers.

They give any amount of draft you want, where you want it and when you want it, and they do it with from 25 to 75 per cent. less steam for driving than any other blower on the market.

You need Coppus Turbo Blowers. Let us hear from you.

Why the Fire Underwriters Approve Nonpareil Corkboard for Cold Storage Rooms

Here are the results of a fire in the International Provision Company's Packing Plant, Brooklyn, N.Y., which happened June 24, 1913. Here, as in many other cases, Nonpareil Corkboard definitely proved its fire-retarding qualities. Ignited cork will not support combustion itself, and the solid, compact construction possible with Nonpareil Corkboard leaves no concealed air-spaces in the walls to act as flues and assist in the spread of the fire once under way.

Interior view of one of the cold storage rooms practically undamaged. The cement finish was cracked just a little, due to the intense heat getting into the rooms through the open doorway.

A solid Nonpareil Corkboard partition, four inches thick, at the end of a cold storage room. The fire destroyed the Portland cement finish, but the corkboard was damaged very little. The interior of the room remained intact.

Is it surprising that the National Board of Fire Underwriters have approved Nonpareil Corkboard? Their approval has resulted in reduced insurance rates in many sections of the country, not only on the buildings insulated with Nonpareil, but on their contents as well.

Armstrong Cork & Insulation Company

504 McGILL BUILDING MONTREAL, QUEBEC, CANADA

Also manufacturers of Nonpareil Cork Covering for brine, ammonia and ice water lines; Nonpareil Insulating Brick for boiler settings, etc.; Nonpareil High Pressure Covering for steam lines; and Circle A Cork Brick for floors of cold storage rooms.

Refrigeration—A National Demand

The nation-wide appeals for the conservation of food products is greatly increasing the demands for mechanical refrigeration. Ice-making and Refrigerating Plants all over the country are overhauling and improving their equipment so that they may supply this demand and reap the increased profits.

Quality in refrigerating machinery, under present conditions, is more to be valued than ever before. An interruption of operation will mean a definite loss.

York Ice-making and Refrigerating Machinery is known universally as the Standard. There's a York Machine to meet every practical condition of mechanical refrigeration, and we are always ready to advise with prospective customers concerning their requirements and then to furnish the plant best suited to meet his conditions.

Let Our Engineers Help You. Write us about your problem.

The Publisher's Page

TORONTO OCTOBER, 1918

The Clean, Straight Road

NO one knows better than an advertiser that all the investment he has made in the years of building his business through advertising can be knocked into a cocked hat by a few pieces of unsatisfactory product.

No one knows better than he that ONE proved instance of departure from square dealing will instantly bar him from the pages of every reputable publication—his marketing medium.

There is no secret diplomacy in advertising in legitimate publications. There never can be.

There is no commercial bribery in orders placed through the open claims of consistent advertisers.

The advertiser cannot afford to profiteer or to cut quality. Only the firm that has discontinued advertising and is planning to go out of business can do so.

Remember the odium that is bound to attach to the man who has recommended the purchase of goods which fall down—whether their failure is through intentional scrimping or blundering lack of knowledge.

Remember the loss in time and production, as well as the cost of replacing, when equipment fails to fulfill the claims made for it by some irresponsible salesman. Whether his firm authorized such claims or not, the loss is on you, if that firm is not a business builder—an advertiser backing his claims with a "make-good" policy.

Think these facts over, Mr. Engineer, when you are making out your next requisition for supplies, or when you make that recommendation for equipment.

Think them over, Mr. Owner, when you are about to put your O.K. on your engineer's requirements.

POWER HOUSE

Conservation and Its Relation to the Power Plant

Cause of Fuel Shortage—U.S. Government Measures—Hydro-Electric Power—Use of Factory Refuse

By T. H. FENNER, Associate Editor

THE war has brought many trials and hardships in its wake, but it has also been instrumental in awakening keen public interest in a subject that formerly held only academic interest to the majority of people. The subject is that of conservation of the great natural resources of the North American continent, and particularly the conservation of coal. Coal has always been so easily obtainable, at a moderate price, that any attempt on the part of the engineering profession to arouse interest in promoting means to ensure its more efficient use, have met with but slight encouragement from those to whom the matter should have appealed the most. Fuel costs have been such a relatively small portion of the general manufacturing costs, that managers of industrial plants paid but little attention to them, in proportion to other items of producing expense, and looked on them as a sort of necessary evil, to be made the best of. However, the conditions arising out of war time demands, aroused all kinds of coal consumers to the necessity of a change in methods, and that speedily.

The Fundamental Cause of the Shortage

The main cause of the great falling off in quality of coal being distributed and the difficulty of obtaining it, was the largely increased demand by the many new factories established for manufacturing war material, and a marked decrease of production at the mines, due to the shortage of labor and the relatively low production of the labor employed. Wages were high, and the men could earn a higher wage than ever before in a shorter time. As the production was falling short of the demand, far less care was employed in the inspecting and screening of coal at the mines, and grades of coal were shipped which had hitherto been considered unmarketable. As a great many of the plants were burning coal very inefficiently even when getting a suitable grade, the loss with the lower qualities was enormously increased, and in a great many cases, difficulty was experienced in keeping the plant running. This attracted the attention of many factory executives who had never before considered operations in the power house to any extent, and when the railway congestion of last winter resulted in conditions that caused the compulsory closing down of the greater portion of the industrial and commercial life of both Canada and the United States on a certain number of days, fuel conservation had become a real live consideration. However, the real object of the heatless days was to relieve the railways of the congestion under which they were handicapped, more than to actually save coal.

Earlier Movement For Conservation

Before the critical situation of last winter had been reached, the representative men of the manufacturing, mining, and power industries had been called into conference with the government in both countries, with the object of fixing on ways and means of reducing consumption of coal without dislocating the essential industries of the countries, and to make these measures permanent, and not merely for the time of stress they were undergoing. There are two main sources of waste of fuel, one being that due to the waste of culm, silt, and small sized coal at the mines themselves, and the second the waste due to imperfect combustion of the coal under the boilers and in the furnaces of the consumers. That a considerable proportion of the small size of anthracite, and also culm and silt, now being allowed to go on the refuse pile can be used to advantage at the mines for supplying light, heat and power, has been proved beyond question, and is actually being done at a number of the mines, thereby releasing a corresponding amount of the steam sizes for distribution to the consumers.

Amount Of Waste At The Mines

It has been estimated by competent authorities in the United States that about one ton of anthracite is consumed at the mines for each eight or nine tons produced. It is estimated that the production of anthracite for the current year, that is from April 1st, 1918 to March 31st, 1919, will be in the neighbourhood of 80,000 000 tons. If the waste products could be reclaimed, and used for power production at the source, it would mean adding an additional 8,000,000 tons to the industrial users supply for the year. There are two kinds of waste in the production of anthracite, the first being the culm, or sizes smaller than 3/32 of an inch, and secondly the rock refuse. The average production of culm to tonnage mined runs about 15%, so that taking the statistics of anthracite produced from 1830 to Jan. 1st, 1918, the culm production in that time amounted to approximately 350,000,000 tons. All this is not available, as probably 50% of it has been taken into the mines for roof support, etc., leaving in the whole anthracite field about 175,000,000, available for use. The heat value of this culm is high, under proper conditions of burning, by the installation of proper preparing plants at the mines, where this culm can be pulverized with a predetermined amount of bituminous coking coal, it can be used successfully in locomotive boilers, while in stationary boilers it can be used without the addition of any mixture. The result of various tests with the fine sizes of anthracite coal have demonstrated that by using a mixture of about 30% fine anthracite with 70% bituminous coking coal, evaporative results equal to those given by a straight butuminous coal can be obtained, even with hand firing. The writer has personal knowledge of one Canadian plant burning a low grade anthracite consisting of about 40% No. 2 Buckwheat, 40% No. 3, and the remainder No. 4 and smaller, with an ash content of from 17% to 22%, with hand firing, and getting fairly good results, without the addition of any bituminous. With a proper mechanical stoker outfit, the same grade of coal would probably give from 15% to 20% better results. In the Canadian bituminous mines most of the small coal is used at the mine, in some cases used in coke ovens, and in others pulverized and burned under the boilers in a central power house, from which power is delivered to the various underground workings.

The Least Excusable Waste

It is in the boiler rooms and factories of the industrial plants that the greatest amount of preventable waste occurs. In

the United States where there are a much greater number of high powered plants than is the case in Canada, the average efficiency is higher, but at that it is doubtful if it exceeds 60%, while in Canada it is probably 10% lower than that. The large majority of plants in Canada are of the one boiler variety, where little or no attention is paid to means of promoting efficiency. When it is considered that 40% of the total coal mined, is burnt under the boilers of manufacturing and electric generating plants, the amount of saving possible by an increase in average efficiency of even 10% can be readily imagined. On the ways and means of achieving this desirable result, articles without number have been written in the past two years and manufacturers of coal saving appliances have contributed to the general knowledge on the subject through their advertising matter. However, these means have evidently not been sufficient to get the power users interested, so the U. S. government have taken more drastic steps to ensure the co-operation of the consumers.

U. S. Government Measures

The United States government have approached this matter of fuel conservation as they have all matters connected with the prosecution of the war, and even to those little enough inclined to find cause for praise in anything done by the U. S. the effectiveness of the measures taken is apparent. What they have done in effect is to put a premium on efficient steam production. Realizing to the full the probable effects of the continuation of present wasteful methods the fuel controller of the U. S. government has presented the power plant owners with the alternative of producing their power economically, as regards fuel consumption, or being put in the position of not having any fuel to consume. They have not done this in any spirit of antagonism to manufacturers, or in a manner to suggest discrimination between the different interests, but in a way that clearly shows they wish to help those who will help themselves.

A power plant efficiencey campaign has been inaugurated, which will embrace every State in the Union, and every power house in each State. An administrative committee has been formed, and under their jurisdiction a field force has been mobilized, whose duty it will be to personally visit every one of the 250,000 steam power plants in the country, and investigate their working conditions right on the spot, offering their help where necessary. As a preliminary to this a questionnaire has been drawn up, and sent to each plant in the country. The questions set embrace all the fundamental points of economical working in the plant, and to each question a certain value has been given. The plants will be rated according to the number of points given to their answers, and those gaining the highest number of marks, or in other words, showing the greatest efficiency, will have the first call on whatever coal is available. The fuel control board has power to shut down completely any plant which in their opinion is excessively wasteful in its operation. The questionaire is produced below. This is the best and fairest means which have yet been designed, to deal with the allotment of coal to the different plants, and gets down to the bed rock of the situation, and if the system is followed up and worked out as it has been designed, many million tons of coal will be saved per year. The plan deserves the earnest co-operation of the consumer, as by following out the suggestions of the questionnaire, he will not only be relieving the coal situation generally, but saving himself money into the bargain.

Number	Hp	Kind of Draft: Nat'l	Forced	Induced	How Fired: Stoker	Hand	Total Hp	Remarks

FIRE-TUBE BOILERS

Number	Hp	Kind of Draft: Nat'l	Forced	Induced	How Fired: Stoker	Hand	Total Hp	Remarks

MOVABLE BOILERS*

Number	Hp	Type	Remarks

* In the rating of the plant movable boilers will be considered separately. The questionnaire does not call for information regarding movable boilers except as per above table. The influence of movable boilers on the rating of the plant will be left to the judgment of the Administrative Engineer.

Kind of coal ..... Bituminous ..... Semibituminous ..... Anthracite
Size .....

Tons of coal of 2,000 pounds used during twelve months ending May 1, 1918.....
Months of operation of plant during the same year .....
Approximately what percentage of live steam is used for:

	Winter Per Cent.	Summer Per Cent.
(a) Making power		
(b) Heating building		
(c) Process work		

Is purchased electric power used?.....
If so, how many kilowatt-hours consumed during twelve months ending May 1, 1918?

Records

Are records kept to show any of the following information? Answer "Yes" or "No" in table.

	By Shift	Daily	Weekly	Mont
Water evaporated by boilers				
Coal consumption by boilers				
Flue gas analysis				
Feed-water temperature				
Steam pressure				

ENGINE EQUIPMENT

STEAM UNITS—ENGINES, TURBINES, PUMPS

Type	No.	Rating: Initial Pressure	Hp.	Kw. or Cu. Ft. Per Min.	Condensing	Noncondensing	Type of Valve Gear
Simple							
Compound							
Turbine							
Steam Pumps							

What changes have you in progress which are expected to reduce your fuel consumption?
.....
When will they be in effect?
.....
Further remarks by owner:
.....

Note to Owner: If sufficient space is not available in the questionnaire, please attach an extra sheet with the additional information.

Recommendations by the Fuel Administration

That provision be made for weighing and recording of the fuel used each shift or day.

That feed water be heated and measured.

That provision be made for an adequate supply of air to the fuel and convenient means provided for the measurement and control of the draft.

That provision be made to keep boiler surfaces clean inside and out.

That the grates be in good repair, that settings, breeching and access doors be free from air leakage, and that boiler surfaces wasting heat be covered with insulation.

That the surfaces of steam piping, drums and feed-water heaters which waste heat or steam by radiation be properly covered with insulating material.

That exhaust steam be utilized wherever possible, to the exclusion of direct steam from the boilers. The plant should be so designed that no more exhaust steam will be produced than can be efficiently utilized in heating or process work.

That a competent man in the plant be detailed for the work of fuel conservation in the boiler and engine rooms.

That a competent man or committe be detailed for the work of fuel conservation in the building or shop outside of the power plant.

(a) FUEL: Value of question, 9. Mark received . . ..
Question 1. What provision is made for weighing fuel used each shift or day?
Question 2. What records are made of fuel used each shift or day?
Question 3. What grate surface is in use each shift, exclusive of banked fires?
Question 4. Total coal used each shift exshift exclusive of banked fires?

(b) WATER: Value of question, 15. Mark received . . ..
Question 1. What provision is made for heating and continuous measuring of feed water (check answer in table below)?

Heating.	Means Used for Measuring.
Open feed-water heater ..	.....
Closed feed-water heater..	.....
Exhaust steam	.....
Direct steam	.....
Waste heat economizer...	.....

(c) AIR SUPPLY: Value of question, 12. Mark received .....
Question 1. Are means provided for measuring the draft over the fire?
Question 2. Are means provided for determining the excess air by fluegas analysis?
Question 3. Are dampers provided for equalizing the draft in the furnaces?
Question 4. Is there a convenient means for regulating the draft by main or uptake damper?
Question 5. Is there an automatic damper regulator in working order?

(d) CLEAN HEATING SURFACES: Value of question, 12. Mark received.....
Question 1. What provision is made for keeping soot and ashes from boiler-heating surfaces (mark answer in table below)?

Steam lance for blowing soot by hand.....	
Mechanical soot blower.....	
Brushes or scrapers.....	

Question 2. How often are the soot and ash cleaned from the boiler-heating surface?
Question 3. What provision is made for keeping scale and sediment out of the boiler (check answer in table below)?

Chemical treatment of feed water in the boiler...
Chemical treatment of feed water outside of boiler
Filtration of feed water in open iced-water heater
Filtration by means of feed-water pressure filter
Other means ....
Water is free from scale or sediment without treatment . .

Question 4. What means are used for removing scale from the boilers?
Hand..... Mechanical.....

(e) BOILER AND FURNACE SETTING: Value of question, 20. Mark received....

Question 1. Are the grates warped, broken or otherwise defective?

Question 2. Check air leaks observed, as follows:
Leaks in boiler setting.....
Openings between boiler and setting.....
Badly warped fire-doors.....
Badly warped cleaning or access doors.....
Leaks around blowoff piping.....

(f) INSULATION: Value of question, 7. Mark received . . .

Check any of the following items where saving could be made by covering surfaces with insulation:
Exposed drums of boilers.....
Exposed shells of boilers.....
Steam piping in boiler room.....
Steam piping in engine rom.....
Feed-water heater .....
Exhaust-steam piping where fuel could be conserved by covering .....
Feed lines .....

(g) ENGINE-ROOM AND HEATING SYSTEMS: Value of question, 15. Mark received . . .

Question 1. Is exhaust steam used: Entirely..... partly.....not used?.....

Question 2. State service for which this steam is employed: Heating.....Cooking.....Dry room .....Tank heating .....
Low-pressure turbines .....
Other purposes.....

Question 3. Is there an excess of exhaust over requiremnts?

	Day	Night
Winter . .	.....	.....
Summer . .	.....	.....

Question 4. Is there any low-pressure live steam used in the plant?.....
At what pressure?...lb. gauge.
For what purpose?.....
Heating..... Cooking.....
Dry room.....Tank heating .....Other purposes.....

(h) SUPERVISION: Value of question, 10. Mark recived .....

Question 1. Has the owner detailed a competent employee to supervise the work of fuel conservation in the boiler and engine plants with directions to report weekly on measures for economy and progress in conservation of fuel?
Name and title of this employee
.....
.....
.....

Question 2. Has the owner appointed a man in charge of the work of fuel conservation outside of the boiler and engine rooms described under Recommendations?
Name and title of this employee
.....
.....
.....

What Canada Is Doing

When we turn to the means adopted in Canada towards effective conservation of fuel, we do not find evidence of a very strong effort having been made. In so far as the utilization of the inferior coals of the western fields are concerned, active steps have been taken to ascertain how they can be used in the best manner. Experiments have been carried out in burning lignite in gas producers, and also under steam boilers and good results have been achieved in both cases. The Canadian government has very recently appointed a board of prominent engineers to thoroughly investigate the properties of the lignite coal of the prairie provinces, but considerable experimental work had already been carried out by provincial governments. It has been demonstrated that lignite containing a high amount of moisture can be successfully handled by the use of a special design of furnace, which can be built at but slight expense. If these fields could be fully utilized, it would release not only higher grade coal, but a large amount of rolling stock, to the eastern part of Canada. However, in this direction at least, the government seems to be awake. It is in the direction of securing more efficient consumption of coal in steam power plants that the government appears to have exerted itself only half heartedly. No positive measures seem to have been adopted, the only tangible evidence of interest in the matter, having come indirectly by way of the Manufacturers' Association. This came about in the following way. The government invited the Manufacturers' Association to consider the question of fuel conservation, and in conjunction with representative engineers, to draw up a form to be distributed to all power plants in the country, which could be used as a guide to fuel conservation. The form here reproduced was drawn up by Mr. J. O. B. Latour chief engineer of the General Accident Assurance Co., of Toronto, and adopted for distribution. The advice contained in this circular is excellent, and if it was followed out conscientiously, would result in great savings, but there is the "if." These circulars were supposed to be hung up in the boiler rooms, and engine rooms of every power plant, and the advice therein contained carefully assimilated and acted on. Will anybody acquainted with the average fireman believe for one moment he will give that circular more than a passing glance. How many of those excellent circulars were hung up and carefully studied, and how many were looked at and then thrown in the furnace? The men who were most in need of the advice would be the ones to throw it in the fire. with the explanation that they "knew all that before." Many of them do know it, but don't act on it. That is not the way to get efficiency methods introduced into the boiler and engine rooms. It needs a definite spur such as the U. S. government has applied to get things moving in the right direction. This fuel conservation question is too big a thing to be handled by one or two men. It requires the services of trained men preferably experienced power house operators with a special knowledge of combustion problems, to visit the plants with the authority of the government behind them, to see that the best available means are being used and to instruct the staff where necessary along the proper lines. It is not a question of forcing manufacturers to put in expensive mechanical plants, but merely of bringing the existing apparatus up to its best condition.

Hydro Electric Power

There seems to be an inclination on the part of the Fuel Controller's office, to strongly recommend the use of electric power, wherever available, as a substitute for steam power. Now, there are many cases where small manufacturers can buy power cheaper than they can produce it with their own plant, and save coal, if power production takes the larger part of their consumption. In the majority of cases in eastern Canada, at least, the percentage of coal consumed for power production alone is a very small part of the total consumption. It is a safe thing to say that in plants that heat with exhaust steam, and use steam for process work, the consumption of coal for power purposes only, does not average more than 20% of the total. In this case the introduction of outside electrical power would affect an actual fuel saving of 20% in the summer months only, while in the winter the fuel consumption would be the same as before, while the electric company's charges would still be going on. Some of the smaller companies selling electric power have tried hard to get business by the fuel conservation lever, and it is to be hoped that the office of the Fuel Controller will not be used as an assistant to securing business for these companies, unless definite savings can be shown, without a prohibitive investment by the manufacturer.

Co-operation Between Factory and Power House

There are ways and means of cutting out waste in factory steam plant operation, outside of the points usually dwelt on. The subject of air leaks in boiler settings has been preached, and written on continuously for the last two years, as have flue gas analyses, clean fire and water surfaces, and steam pipe insulation. However, there are some smaller points which are productive of much waste, and do not seem to ever be mentioned in the various contributions to the subject.

A great many processes involve the use of hot water, frequently in open tanks, as the dipping tanks for nickel plating work, washing water, etc. It is a common thing to see the steam valves on these tanks set so as to keep the water in the tank violently boiling the whole day long, whether in use or not. This could be checked if anyone in the department took sufficient interest but very rarely they do. The fitting of thermostatic valves to control the supply of steam to these tanks, keeping them at the required temperature, would result in a considerable saving at small cost. When exhaust steam is available the water supply can be heated to say 200° before being sent to the tanks thus further cutting down the live

steam requirement. Small details such as keeping washers in hot water taps tight, do not look as though they would affect steam consumption a great deal, but all the hot water wasted has to be replaced with cold, and this cold water has to be re-heated. If all the hot water wasted in even a moderately sized factory were to be measured, the results would furnish a surprise. In drying work such as Japan baking, lumber drying and kindred processes, the initial heating could well be performed with exhaust steam, and live steam turned on only when the limit of temperature from exhaust had been reached. When exposed lumber drying kilns are operated in winter, it would frequently be practicable to use exhaust steam to keep the temperature high enough to prevent freezing while loading and discharging in winter, and to eliminate the surface moisture, making a further saving in live steam.

Factory Refuse

An operation which usually causes much hard feeling and incidentally, lowered efficiency, is the manner in which factory refuse is delivered to the boiler room for burning, and the manner it is burnt after it gets there. Factory refuse means a variety of things, depending on the product, and some of it has relatively good heating value, while others is just plain dirt. As a rule it is delivered to the boiler room just as it is collected, scraps of paper being mixed up with pieces of old boxes, sanding belts, old nails, pieces of leather belts. This makes an uninviting and awkward heap for the fireman to handle and he usually does it by means of a pitchfork to lift it up with, ramming it into the fire with his hands, feet and body. After introducing one pitchfork load, he leaves the fire door open while he collects another load, and shoves it in in the same manner. This goes on in the same way till the front of the fire is full, when he shoves it back as far as he can with his rake, and then goes ahead again. The furnace door is open for 15 or 20 minutes continuously and the state of the fire when he is finished is usually such that all that can be done is to pull it out. The pieces of hoop iron, nails, etc., in the refuse form a slag which effectually blocks the air passage through the coal bed, which in turn forms into a mass of hard clinker. Now, a little co-operation here would make it possible for incombustible rubbish to be separated out, and the remaining refuse delivered at a time when it could be burned to the best avantage. Generally speaking, it can be better burned at night, when the load is light. In any case, it should be burnt only on a fire that has been burnt down ready for what is meant as a saving. In plants where there are more boilers than required, it is worth while to fit one up with a Dutch oven, and reserve it only for refuse destruction. Another point the factory staff can help in is to see that aircocks on machines where air is used for blowing such as moulding machines in the foundry, are not left partly open when not required. All these may appear to be minor points, but collectively they mean a whole lot to any plant, and when they are multiplied by the total number of plants in the country, they form an item well worth considering.

Necessity of Making a Real Effort

Canada depends so largely on the United States for her coal supply, that it behoves her to make a strong and concerted effort to improve conditions. If power users in the States are to be allowed coal only in so far as they can show they are not wasting it, it can hardly be expected that they will cheerfully submit to coal being shipped to Canada to other inefficient users. Increased efficiency is largely a matter of effort, and if the consumers cannot make the effort, then it is up to a paternal government to do it for them, taking care to play no favorites, but being absolutely firm and impartial, and in this Canada might well follow the lead of her big neighbour.

FUEL SAVING "DON'TS"

by
J. O. B. Latour, Chief Engineer,
GENERAL ACCIDENT ASSURANCE CO. OF CANADA.

1. DON'T fill the furnace with the intention that there will be no necessity for any additional fuel for the next two to four hours. This is quite a common practice with heating boilers, and with bituminous fuel results in very great waste.
2. DON'T regulate the draft by closing the ash pit door, but regulate it with a damper in the smoke flue or pipe between the boiler and the chimney. This also applies to any kind of furance.
3. DON'T allow any cracks in the brick setting of the boilers, because cold air will enter through these cracks and absorb the heat that should have been transferred to the boiler.
4. DON'T permit the use of grates of any kind which are in bad condition. This will permit the unconsumed fuel to fall through to the ash pit and be shovelled out as ashes or waste.
5. DON'T use a grate that is larger than will permit the burning of at least 12 lbs. of coal per sq. ft. of grate per hour.
6. DON'T permit any pipes or boiler surface to remain uncovered, unless it is necessary to transmit the heat through the surface of that pipe to the room in which it is located.
7. DON'T permit any point in the boiler or any pipe connected thereto to leak.
8. DON'T permit any valve to leak which is located on a pipe supplied by the boiler. This is a very common source of loss. All valves should be positively tight when closed.
9. DON'T attempt to control the quantity of condensation to be collected from any pipe or other apparatus by hand control. There are a large quantity of good serviceable traps to collect these returns of condensation and they should be returned from these traps to the boiler.
10. DON'T permit any surface on the boiler exposed to the furnace heat to become covered with soot or ashes. The tubes should be cleaned at the very least daily.
11. DON'T use live steam for heating rooms, liquids, or other substance when there is exhaust steam from engines or pumps available. If the exhaust steam is not of sufficient temperature to heat the room, the liquids, or other substance to the required temperature, arrange your heating to be done in two stages; for instance, water could be heated to nearly 212 degrees by exhaust steam, then passed through to another vessel to be heated to the desired temperature with live steam.
12. DON'T feed a boiler with cold water when there is exhaust steam available to heat it. Every eleven degrees in temperature that feed water is raised by heating by exhaust steam there is a saving of 1 per cent. in fuel, and in winter time especially feed water is very seldom any warmer than 42 degrees. If this water is heated 212 degrees it will then effect a saving of 15 to 16 per cent.
13. DON'T allow the main steam valve on any engine or pump to leak. This is a very common fault, due to the fact that the leak is not seen.
14. DON'T allow the piston of any engine or pump to leak. This is also a very common defect permitted to go on day after day simply because the leak is not seen.
15. DON'T take it for granted that pipes that lead to sewers, blow-off tanks, or other places of discharge, are tight. If the pipe is warm between the stop valve and the source of discharge it will generally pay to investigate a little closer, because it generally is a sure sign of leakage, with great waste.

Power Plant Management; The Use of Instruments

Why it Pays to Keep Your Finger on the Pulse of Your Power Plant—Poorly Operated Plant a Direct Aid to Germany in View of Coal Shortage

By ROBERT JUNE

YOU wouldn't knowingly and willingly help Germany—would you? Of course you wouldn't—not in any apparent and direct manner. But what about indirect aid and comfort?

You don't want to give that any more than you do open assistance to the enemy's cause. Yet you are deliberately doing this very thing, when in view of the existing coal shortage, you fail to maintain the highest possible operating efficiency in your boiler room. The fact that the power you generate may go directly into the manufacture of supplies for our war machine, makes no difference. It is your patriotic obligation to conserve coal wherever practicable, in order that more war supplies may be made.

Now, how are you to know whether you are at all times maintaining the highest practicable operating efficiencies in your boilers? Well, how does your physician determine the operating efficiency of your body? Through the use of guaging and recording instruments, doesn't he? And just as the medical man needs his watch, thermometer, stethoscope, blood count apparatus, and blood pressure machine, so does the power plant operator need his clock, draft guage, Orsat, CO_2 recorder, steam flow meter, and flue gas temperature recorder.

How one Power Plant Operator Utilizes the Clock.

I have mentioned the clock first. It isn't the most important instrument, but it belongs in every boiler-room, and can be put to unsuspected uses. One power plant operator of my acquaintance has had a great deal of difficulty, due to general industrial conditions in his vicinity, in getting labor of any sort, experienced or inexperienced, for his boiler-room. He sometimes has had a complete labor turnover in two weeks. Green hands have not only not known how, they have not known when to fire, and they have resented the forman's constant admonition to fire up, or to withhold firing and give combustion a chance. As a result, firing has been exceedingly erratic, and boiler efficiency something to dream about.

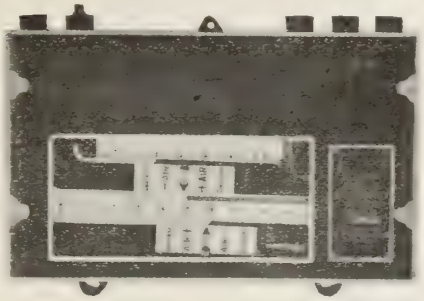
The irregular firing phase of the problem has been solved by connecting up the clock with an electric bell. Every five or six minutes the alarm sounds, and promptly on the dot, the fiire doors are opened in unison, the fires are sliced (if required) and a standard number of shovels of coal thrown in the furnaces.

This standardization of time of firing, has produced a marked increase in the efficiency of this plant. The boiler room foreman has noy only to devote his attention to condition of combustion. Contrary to expection, the firemen have taken kindly to the innovation. They receive a bonus for high CO_2 and have found their pay checks increased about 10 per cent. In addition they are actually shovelling less coal and have more frequent rest periods.

Changes in load involving the cutting out or in of boilers at stated times, should always be scheduled on a bulletin board, arranged with a clock in close proximity.

I make this statement with due consideration of all the factors entering into successful boiler operation. It enables the fireman to produce the largest amount of steam with the least amount of coal handling.

The draft required to effect a given rate of combustion depends upon the kind and condition of fuel, the thickness of fire, type of grade and efficiency of combustion, and can only be found accurately by experiment. For every kind of fuel and rate of combustion, there is a certain draft with which the best results are obtained. The curves in Fig. 1 give the furnace draft necessary to burn various kinds of coal at the indicated rate of combustion for average conditions. These curves allow a safe margin for economically burning coals of the characters noted. Specific figures for the various types of stokers may be obtained from the manufacturers.



THE BLONCK DIFFERENTIAL DRAFT GAGE OR EFFICIENCY METER

When combustion is progressing properly, the quantity of gases will be in direct proportion to the load. The boiler through which the gasses pass has a constant resistance (constant, that is, for the individual boiler—different sizes and makes of boilers have different resistances.) The function of the draft guage is to indicate the difference in pressure between the point or points with which it is connected and the atmosphere. A simple draft guage is connected to one point, a differential to two.

A draft gauge, connected to show the pressure drop through the fuel bed, in connection with one showing the drop through the boiler, will indicate any change in the fuel conditions. A relative increase in the fuel bed drop will indicate that the bed is becoming thicker, or that it is coming clogged with clinker, etc. If the pressure drop becomes less, it indicates that there are holes in the fire, or that the fuel bed is too thin.

There are a number of good draft guages on the market. One of the best is the Hays.

The Ellison consists of multiple differential guages, and a simple U-guage. This latter indicates the blast, while the upper inclined guage shows the furnace draft, and the lower inclined gauge the drop between the flue and furnace (boiler resistance.)

The Blonck efficiency meter consists of two differential guages, one indicating pressure drop through the fuel bed, the other through the boiler.

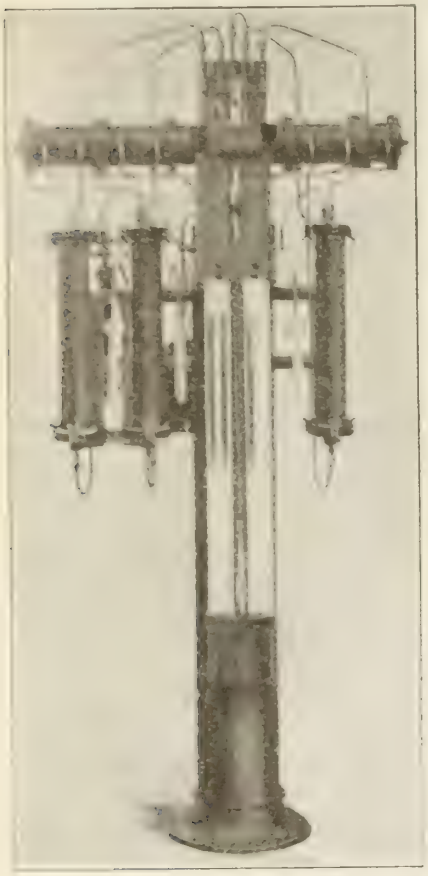
The Bailey boiler meter combines the differential guages of the efficiency meter, with a steam flow meter. The two draft guages, etc., are of the recording type, and are enclosed in the same case with the steam flow meter, recording on one circular chart. The pressure drop in the boiler gas passages is an indication of the quantity of air passing through the boiler, and the pen recording this pressure is set to record just ahead of the steam flow pen. When the two lines practically coincide, the air is in the proper proportion for the load on the boiler. A pen controlled by two different pressure meters of the inverted bucket type, attached to the arms of a balance, called the furnace indicator, records on the outer portion of the chart. The steam record is made as a percentage of the rated capacity of the boiler.

The pressure drop across the fire varies with the resistance of the fuel bed, and also with the rate of flow of air through the fuel bed. The furnace indicator compares the pressure drop across the boiler, eliminating effects due to the rate of flow of air, and thus obtains a net result which varies only with the resistance of the fuel bed. While this type of apparatus indicates what is going on in the furnace boiler, the operator must have sufficient intelligence and skill to be able to interpret its indications and adjust conditions.

In concluding this discussion of draft, and draft guages, I cannot do better than quote a statement once made by that master engineer of boiler-room operation, Joseph W. Hays: "Visit your boiler-

Editor's Note—This is the fourth in a series of articles by Mr. June on Power Plant problems. Succeeding articles deal with principles of heat absorption, mechanical stokers, influence of furnace design, coal and ash handling equipment, storage of coal, abuse of steam, etc. Later articles sum up the best current practice in the business management of the Power Plant. The series is timely and should prove of value to our readers.

room to-day and note how your firemen manage the drafts. If there are draft gauges on your boilers you will first be interested to note what a variety of drafts you have. You will also be interested to see whether the firemen are paying any attention to the guages. If they do not, it is the fault of somebody about the plant—not the firemen. It is a waste of time and money to equip your plant with anything that is not going to be used. Now watch the firemen.



THE UEHLING CONTINUOUS CO RECORDER

"The boiler dampers are wide open. The damper in the main breeching, if there is one, is wide open also. The firemen act upon the theory that draft is made to be used and that if some draft is a good thing, all of the draft that can be obtained must be better. They take the whole box of pills at one dose.

"The rule, when designing a power plant, is to provide for an excess of draft. Dampers are furnished in order that the draft may be under control. The better damper has the same relation to the furnace that the throttle bears to the steam engine. The firemen should set the dampers to give the draft that is called for—no more and no less. The dampers should never be wide open except under the most extreme conditions of use.

"You will notice, most likely, that the firemen use the ash-pit doors to check the draft when the steam approaches the popping point. They have discovered that this is a very effective way to quiet the enthusiasm of the boiler. They do not know that it is the wasteful and improper way. If there are draft gages on your furnaces you will observe that the vacuum is greatly increased when the ash-pit doors are closed. This multiplies the inflow of air at all of the cracks, crevices, holes and other openings about the boiler. The uptake temperature raises. Steam is being checked all right, but heat energy is being wasted.

"It is just as easy to close the boiler dampers as it is to close the ash-pit doors, provided the dampers are furnished with the proper means for exercising manual control. If they are not so furnished, somebody's foot slipped. The boiler damper controls should be so arranged that they may be worked, and worked easily from the fronts of the furnaces. The firemen should be compelled to use the dampers in preference to the ash-pit doors. The latter should be removed, if necessary, to get the firemen in the way of using the dampers."

The Why of Flue Gas Analysis

The products of combustion, resulting from complete oxidation of coal, with theoretical air supply, consist chiefly of nitrogen and carbon dioxide, with lesser amounts of water vapor and sulphur dioxide. With deficient air supply the flue gases are found to contain carbon monoxide and carying amounts of hydrocarbon. Excess air results in the presence of free oxygen in the gases. Evidently an analysis of the flue gases offers a basis for judging the efficiency of combustion.

The following are the things to be studied and adjusted:

1. The firing and handling of the fire.

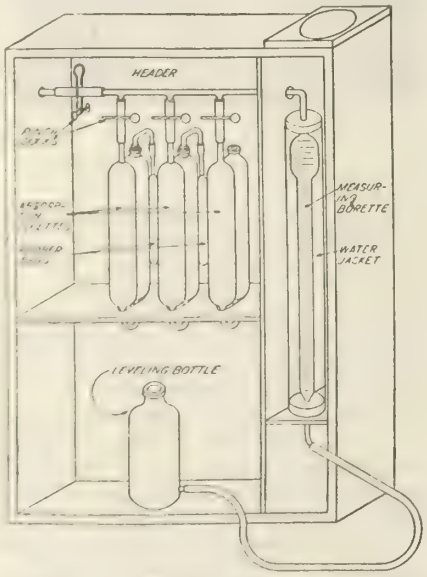
(a) Selection of proper firing method for the coal in use (cooking or spreading methods).

(b) The proper leveling of the fire to keep it free from air holes.

(c) The proper depth of fire.

2. The draft for the thickness of the fire and the load.

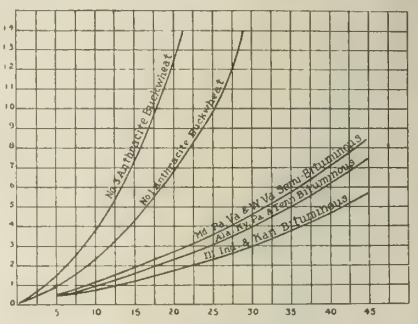
3. The setting, which should be free from cracks.



ORSAT APPARATUS FOR DETERMINING PER CENT. CO_2 IN INDIVIDUAL SAMPLE OF FLUE GAS

4. The secondary air supply, which must be provided to complete combustion.

If the gas analysis is to have any value, the sample on which it is based must be as nearly an average as it is possible to obtain. There is a diversity of opinion as to the best method of obtaining the sample. The Bureau of Mines recommends water cooled tube, or a quartz tube, as preferable to a metal



No 1 Anthracite Buckwheat
No 1 Anthracite Birdseye
Me Pa Va Ky W Va Semi-Bituminous
Pa Ky Va Kan Mo Bituminous
Ill Ind & Mont Bituminous

FIG. 1. DRAFT REQUIRED AT DIFFERENT COMBUSTION RATES FOR VARIOUS FUELS

tube. The A.S.M.E. test code recommend a plain perforated ¼-inch gas pipe. As between the two, the Bureau of Mines recommendation would seem preferable.

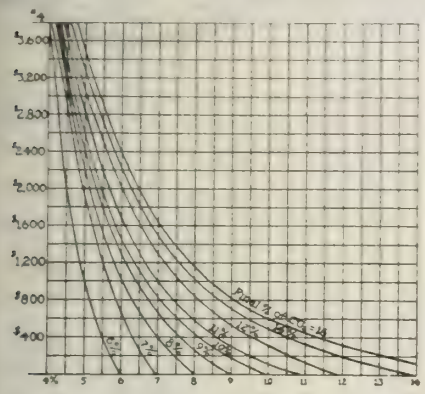
The use to be made of a gas analysis determines the location of the sampling tube. If the total heat losses are the desired data, the sample should include all air leakage into the setting. If this information is to be used in controlling the fire, the sample should be taken at some point before the gases are diluted by leakage through the setting.

Remember the boiler damper in placing the sampling tube so that the tube is not placed in a gas pocket. Particular attention must be paid to preventing air leakage around the sampling pipe, which might give a false indication of the composition of the gases. In a B. & W. boiler the sampling pipes can be thrust through the top blow-role at the last pass. In a Heine boiler the pipes can be run through one of the hollow stay bolts. In a return tubular boiler the top handle can be removed from the boiler doors. Place the tube six inches from the boiler head and above the top row of tubes. If it is put in too far it may come into a dead space. Be sure to get none of the air leakage around the doors. If air leaks in at the rear arch most of it will find its way through the upper arches.

The Orsat apparatus recommended by the Bureau of Mines for C O_2 determination is shown in Fig. It can be purchased either in the form shown or in a modified form from a number of reliable manufacturers. Full directions for its operation are given in the Bureau of Mines bulletins, or may be obtained from the manufacturers.

While hand indicators, such as the Orsat, can be used as a means of studying air supply conditions or for occasional tests, they do not answer the purposes of daily plant operatin, ince

the CO_2 content of the flue gases may, and does, vary widely, rapidly and continuously, due to the fact that the proportions of the air supply, which comes through the fire and in above the fire, are easily upset by throwing on of fresh coal, the burning through of thin spots, accumulations of clinker and ash, manipulation of dampers and fire-doors, etc. It can hardly be said that CO_2 re-



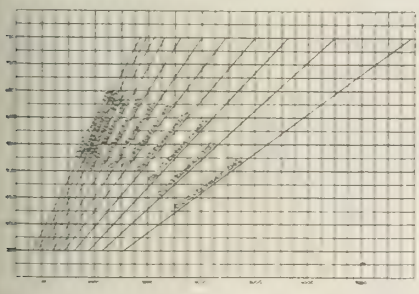
SAVING IN DOLLARS PER YEAR PER 100 H.P. BY INCREASING THE PER CENT. CO IN THE FLUE GASES.

corders act promptly enough to follow the variations in CO_2 from minute to minute, but they do, on the other hand, produce a chart showing an average, which serves as a warning to the fireman, who is careless or incompetent in his management of the fire and draft.

Remember that while high CO_2 indicates a small amount of excess air, it does not necessarily mean correspondingly good combustion.

Low CO_2 may be caused by excess air, insufficient air (high CO), or improper mixtures of the air and gases, but a surplus of air is the cause in almost every instance. The difference between the CO_2 percentages in the last and first passes indicates the air leakage in the setting.

CO_2 is affected by the character of the fuel. The more hydrogen in the



LOSS DUE TO HEAT CARRIED AWAY BY CHIMNEY GASES FOR VARYING PERCENTAGES OF CO

coal, the less CO_2 in the flue gases. If the fuel were all carbon there would be 21 per cent. CO_2 in the setting.

We must not attempt, however, to secure high CO_2 by cutting down the draft only. High CO_2 can be obtained with any draft in reason, either high or low, provided the draft and the fuel resistance are in proper relation. CO_2 percentage indicates the ratio of air used to the air that has not been used. It is sometimes feared that 8 or 10 per cent. CO_2 cannot be obtained without CO in considerable quantities. This is not in accordance with general experience. There is little danger from CO until 15 per cent. CO_2 is reached.

The percentage of CO_2 is the index of the amount of heat being wasted up the stack. It is little realized how large a return will result from a small increase of average per cent. of CO_2. The chart of Fig. shows, for instance, the dollars saved per 100 boiler h.p. operating 365 days per year, 24 hours per day, for various prices of coal, and corresponding to an increase in CO_2 from any original figure to any final figure. Suppose, for instance, that the original per cent. of CO_2 is 7 and that after equipment with CO_2 recorder, the average CO_2 is increased to only 8 per cent. Starting at the 7 per cent. mark of the horizontal line of this chart and rising to the 8 per cent. curve and then running over horizontally to the left, we find that with coal at $4.00, this increase of CO_2 means a yearly saving of $375.00. This, of course, is for 100 boiler h.p. operating continuously. If the load factor instead of being 100 per cent. were only 25 per cent. the saving would be one-quarter of $375.00 or $94.00 per 100 boiler h.p. and for a 500 boiler h.p. 5x94 equals $470.000.

The CO_2 indication answers most practical purposes. If greater certainty is desired after the CO_2 has been brought up to the desired per cent. the CO determination can be made. The formation of CO is due to:

1. Furnaces of poor design.
2. Improper methods of firing.
3. Character of fuel, particularly with reference to the equipment with which it is burned.
4. Improper mixing of combustible gases with the air.
5. Low furnace temperature, so that the gases are cooled below the ignition point.
6. Deficient air supply.

The formation of CO is usually due to insufficient air supply, which, as pointed out by the Bureau of Mines, may be either local or general. Either the local or general causes may be from the composition of the coal. The coal may be fusible, in which case the surface of the fuel forms one solid layer of semi-liquid fuel, which effectively stops the passage of air. At the same time, a large excess of air may be fed into the furnace elsewhere. The same local excess or insufficient air supply may be caused by the fusion of ash on the grates. The volatile matter may be driven off so rapidly after a fresh charge of coal that the average air supply is not sufficient, whereas a couple of minutes after firing it is too large.

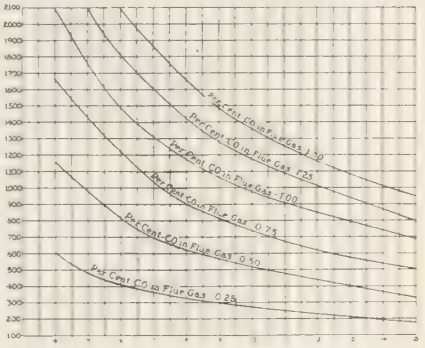
The occurrence of CO in the waste gases is a decided danger of signal, not so much on account of the loss which it represents, but because it is usually accompanied by unconsumed hydrogen and hydro-carbons.

Flue Gas Temperatures and Efficiency

Flue gas temperatures should be taken with a continuous instrument. They serve a number of useful purposes.

1. Call attention to leaks in boiler setting. In case air is allowed to leak into the flues, and mingle with the gases after they have left the heating surfaces, the temperatures may be brought down to almost any point above that of the atmosphere, but without any reduction in the amount of heat wasted.
2. Indicate condition of furnace and boiler, such as:
   (a) Dirty fire.
   (b) Holes in fire.
   (c) Presence of scale on water surfaces.
   (d) Presence of soot on fire surfaces.
   (e) Faulty condition of baffles.

Of the conditions just mentioned, unclean heating surfaces are most important, since they are most prevalent and constant. Many cases are on record where continuous soot removal, such as is obtained by the use of mechanical soot blowers, has affected a



LOSS DUE TO UNCONSUMED CARBON CONTAINED IN THE CO IN THE FLUE GASES

continued reduction in average flue gas temperatures of 80 degrees.

In conclusion, there is no more reason why you should ask or permit your boiler-room crew to work without the instruments we have discussed than to permit them to work without a pressure gauge. Instruments tell your men where they are at. Given knowledge and good intention they will soon improve operating conditions. At present the state insists upon the pressure gauge. The time is rapidly approaching when it will insist upon the other instruments. Forewarned is forearmed. Give your men the needed appliances.

PRINCIPLES AND OPERATION OF MODERN ELECTRICAL EQUIPMENT VIII.

BY A. M. PERE.

IN last month's course an explanation of the operation of generators when changed to motors was given. This subject is interesting in itself and also serves to clearly show the various types of windings used and their relations to each other.

Fig. 1 shows an ordinary shunt wound generator of simple type. The armature is revolving in the direction shown and the simple armature coil has currents induced in it as shown in the small circles to the right and left of the commutator, that is it flowing away from the observer in the left hand conductor and towards him in the right hand conductor. This must be the case for the direction in which the armature is revolved as may be shown by referring to a previous section where currents induced by magnetism were discussed and the right and left hand rules for generators and motors given. A portion of the current generated will flow through the shunt windings and will energize the fields.

If now the shunt generator be supplied with current from an outside source and run as a motor the direction of current flow in the fields will be reversed while the direction of current flow in the armature will remain the same, supposing the current to be supplied in the same direction as that generated or as shown. This will change the polarity of the field magnets as shown but since current is being supplied and not generated the armature conductors will have a tendency move by reason of magnetic drag in an opposite direction to that in which they were driven when the machine was used as a generator. The resultant direction of rotation will therefore remain the same as before. Altering the direction in which the current is supplied will have no effect, as regards direction of rotation because the field current and armature currents will both change in direction and the rotation will be the same as before.

Series Generator and Motor

The only method of changing the direction of rotation of any direct current motor, is to transpose the field connections where they connect with the armature leads.

The series wound machine offers a different problem as will be seen from an inspection of the diagrams Figs. 3 and 4. The generator rotating as shown in Fig. 3 and with connections arranged as shown will generate current as shown by the arrows. The fields consisting of a few turns of heavy wire are energized by all the armature current.

If this machine be changed over into a motor and current supplied, the field current and the armature current will remain the same relative to one another, but the armature conductors will tend to move in a direction opposed to that of a generator under the same polarity. Since there is no change of polarity such as occurred in the shunt dynamo the motor will revolve in the opposite direction to a generator.

Here again the only way to reverse a motor is to transpose the field connections since by a little study of the

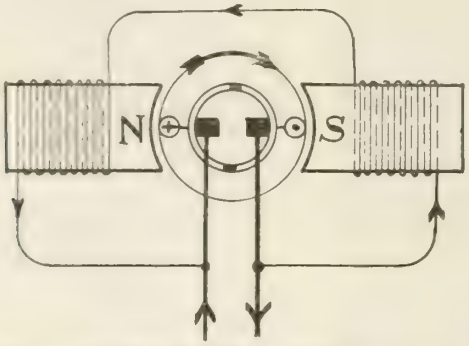

FIG. 1. DIAGRAM SHOWING CURRENT RELATIONS IN SHUNT WOUND DYNAMO

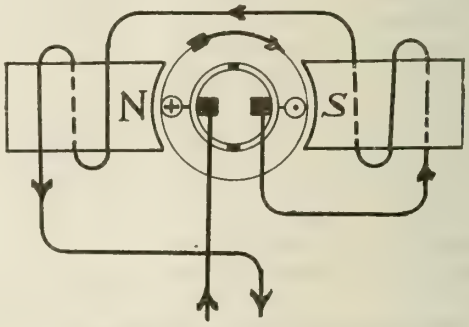

FIG. 2. DIAGRAM SHOWING CURRENT RELATIONS IN SERIES WOUND DYNAMO

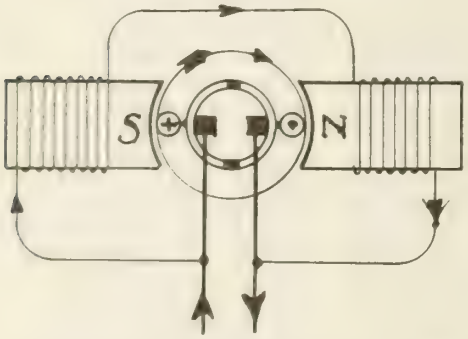

FIG. 3. THE SAME MACHINE AS THAT SHOWN IN FIG. 1, CHANGED OVER AND RUNNING AS A MOTOR. THE DIRRECTION OF ROTATION IS UNCHANGED FOR A SHUNT WOUND MACHINE

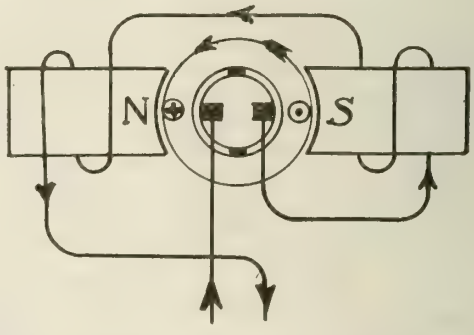

FIG. 4. THE SAME MACHINE AS THAT SHOWN IN FIG. 2 CHANGED OVER AND RUNNING AS A MOTOR. THE DIRECTION OF ROTATION IS REVERSED FOR A SERIES WOUND MACHINE

diagram, it is apparent that changing the direction of current flow into the motor will have no effect just as in the shunt motor.

It should be stated here that a series generator is never used except for very special conditions as series generator is shown mainly for descriptive purposes.

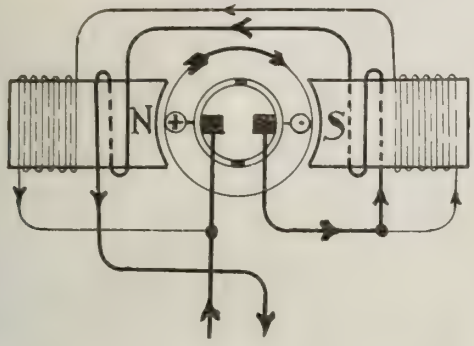

FIG. 5. DIAGRAM SHOWING CONNECTIONS FOR A CUMULATIVE WOUND COMPOUND ENERATOR. BOTH FIELD COILS ACT IN AREEMENT AND EACH SUPPLIES PART OF THE MAGNETISM NECESSARY

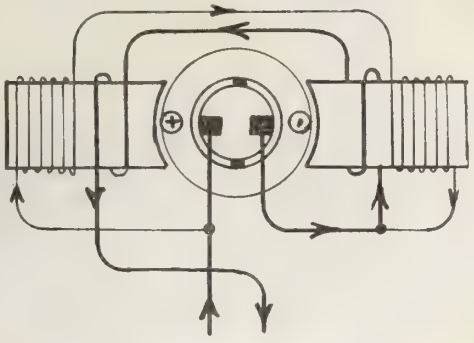

FIG. 6. THE CUMULATIVE WOUND GENERATOR OF FIG. 5 BECOMES A DIFFERENTIAL WOUND MOTOR WHOSE DIRECTION OF ROTATION DEPENDS ON THE RELATIVE STRENGTH OF THE TWO FIELDS

Compound Wound Machines

It was stated in last month's section that a differential compound wound generator will become a cumulative wound motor and vice-versa. As before stated the differential machine is one in which the magnetising effects of the shunt and series windings are opposed while the cumulative wound machine is one in which they assist each other.

Fig. 5 shows a cumulative wound generator, and from an inspection of the windings and their arrangement it is seen that the two field windings assist each other. When this machine is supplied with current and run as a motor it is seen that the current through the armature in Fig. 6 remains the same, the current through the series field coils remains the same but that through the shunt coils is reversed in direction and thus the magnetising effect of the shunt windings opposes that of the series windings. This effect remains the same even if the direction of current flow through the whole machine is changed the two sets of fields opposing one another. It is seen that the cumulative wound generator changes to a differential wound motor and by a similar process the differential wound generator changes to a cumulative wound motor.

To change a differential wound motor into a cumulative wound machine it is only necessary to change one set of field connections, either the series or shunt. To change the direction of rotation of a compound wound motor of either type both sets of field connections must be changed.

In a compound wound dynamo the shunt winding provides the initial excitation sufficient to generate full voltage at no load. The excitation due to the shunt winding is very nearly constant while the series windings supply an increasing amount of excitation as the load increases.

Compound motors are used where the load varies considerably, where the extreme speed variations of series motors would be objectionable, and where sudden increases in the load require increased torque that shunt motors could not give.

Answers to Last Month's Problems

1. Shunt, series and compound.
2. See last month's section and also this month's drawings.
3. No. Because the field excitation drops off with increasing load, and finally reaches a point where no voltage is generated or only that due to residual magnetism.
4. Yes.
5. No, it reverses its direction of rotation.

SYNTHETIC RUBBER

A very instructive communication on the difficulties with which Germany has to contend owing to the dearth of the most important raw materials for the war industries was made by Dr. Duisberg, one of the leading chemists of the Elberfeld Farbenfabriken, in the meeting of the Bunsen Gesellschaft, held at Berlin in April last. It will be remembered that in the years 1910 to 1912 Fritz Hoffmann, of that firm, had succeeded in preparing isoprene and dimethylbutadiene, hydrocarbons somewhat resembling benzene, which on long-continued boiling (for weeks or months, it is now admitted) turned into a substance which showed the chemical reactions and some of the properties of caoutchouc. This synthetic product was used as a rubber substitute or as addition to rubber, and the process seemed commercially possible in those days when rubber was in Germany 30 marks per kilogramme. When the price went down to 4 marks, the Leverkusen works of the firm gave the new process up. There was another process, tried and afterwards abandoned, in these works: reduction of acetone by means of aluminum to pinakone, which is closely related to methylbutadiene. The war once more forced attention on these processes. Meanwhile, however, aluminum and acetone had become equally rare and precious. As regards aluminum the manufacture of the metal was taken up in Germany, which has now three works. With respect to acetone, potatoes had been a raw material, but they could not be spared any longer. Bottinger found that with the aid of the bacillus macerans he could make acetone from putrid potatoes, the fermentation yielding a mixture of about two parts of alcohol and one part of acetone; but the bacillus proved very sensitive, and the process was not a success on a large scale. Calcium carbide was then utilised to a larger extent than before the war; it yields, with water, acetylene which in the presence of a contact substance (mercury salts) is converted into acetaldehyde; the aldehyde can be oxidised to acetic acid; blown over another contact substance the acid loses the elements of CO_2, turning into acetone. This process is worked at Leverkusen, at Hochst and at Burghausen on the Alz. The rubber manufacture was then resumed. The rubber industry was not favourably disposed to the new methyl caoutchouc, however, which was not real rubber, absorbed oxygen from the air, and gave trouble in the vulcanisers. This trouble was overcome by the aid of piperidin and other ingredients. The new hard rubber (ebonite) so improved was equal to the old product and dielectrically even stronger; the accumulator boxes of the U-boats are made of this ebonite. The soft rubber, however, was not perfect yet; at ordinary temperature it resembled leather more than rubber, and became elastic only when warm. The addition of dimethylaniline and of toluidine—both valuable products, it need not be pointed out—cured these defects. In the improved condition the rubber is used for making the tyres for heavy motor vehicles and also for artificial teeth. The Leverkusen works can now supply 2,000 tons of rubber per year, which is about one-eighth of the amount of rubber wanted. Meanwhile Merling has prepared isoprene from acetylene and acetone, and that process, though still in the experimental stage, is also regarded as promising. As to the outlook for these synthetic rubbers in normal times Dr. Duisberg was guarded.—"Engineering."

Description of Some of Europe's Water Powers

Water Powers of Europe of Considerable Value—Description of One of the Italian Plants Developing Power From Water Under High Head

By F. C. PERKINS

THE great utility of the Hydro-Electric power plants in Europe has been wonderfully demonstrated during this great war. The "white coal" is indispensable and those countries which have developed their water power resources appreciate their value as never before in the world. The accompanying illustrations, Figs. 1, 2, 3 and 4, show the Cedegola Hydro Electric Power Station and the reinforced concrete double roof and hydraulic installation, as constructed by Ingegnevi Fratelli Damioli, of Milan, Italy. The hydraulic turbines in this plant were installed by Escher Wyss & Cie of Zurich, Switzerland, as well as those of the Pataras Hyro Electric Plant noted in photograph Fig. 5 and the Kubelwerk Power Plant seen in Fig. 6. The hydraulic turbines of the Arniberg Hydro-Electric Power Station, the general design and details of construction which may be noted in drawings Figs. 7, 8 and 9, were built by Theodore Bell & Co., of Kriens-Lucerne, Switzerland.

The Pataras turbines shown in Fig. 5 operate under a head of 236 meters, utilizing 420 litres per second and developing 1,000 horsepower each, operating at a speed of 375 revolutions per minute. At the Kubelwerk the Escher, Wyss turbines seen in photograph Fig. 6 developed 1,200 horsepower each at a speed of 375 revolutions per minute, the hydraulic head varying from 82 to 92 meters.

It is of interest to note that the Arniberg Hydro-Electric Power Station was built at Arniberg, near Amsteg, on the St. Gothard Railway, ten miles or so above the upper end of the Lake of Lucerene, the head at this station being 2,800 feet. Besides supplying electrical energy to this district, which is thinly populated, and of a non-industrial character, the station serves as a feeder to Altdorf, seven miles further down the valley, and to Rathhausen, on the outskirts of Lucerne. To the former city the Arniberg Station supplies three-phase current at 48 periods and to the latter three-phase current of periods, by a thirty-mile transmission line.

The water power is obtained from two glacier-fed streams and from some springs. The water after being collected in an artificial lake situated 4,500 feet above sea level is led through two parallel pipe lines, each 6,850 feet long, and varying in internal diameter from about two feet to about 18 inches.

The two pipe lines are connected by a cast steel double bend securely anchored to a heavy concrete block and the end thrust on the bend amounts to something like 320 tons. Should repairs be found necessary either pipe line may be shut off without closing down the whole plant. Each pipe line is provided with a waste-water pipe which discharges into the tail race. These waste-water pipes, shown in the drawing on page 6, a plan and elevation of the power-house, are controlled by a sluice valve at the main pipe line and by a regulating valve at the tail race end. The latter valve is of the nozzle type and is used to relieve the sluice valve of excessive pressure when being closed. A section of the regulating valve is shown in Fig. 10.

The station was designed for four turbine units, three of 3,000 horsepower each and one of 1,300 horsepower. Each turbine is connected to the main pipe line nearest the wall of the powerhouse by a wrought iron branch pipe 12 inches in diameter in the case of the larger units and 8 inches in the case of the smaller unit. The tee-piece uniting the branch pipes with the main pipe is provided with a valve whereby each unit can separately be shut off from the source of power. They are provided with balancing pistons to relieve the pressure of 1,200 pounds per square inch under which they have to act and are controlled by spur gear and chain drive from the turbine room. To ensure

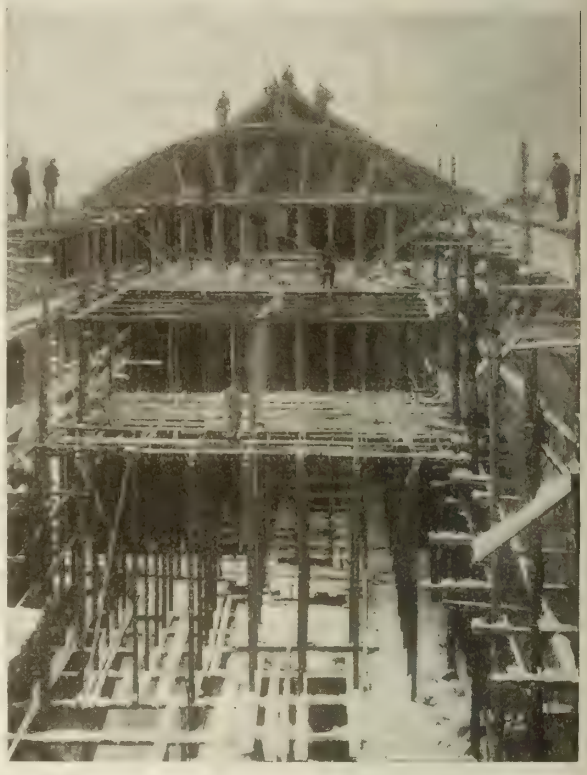

FIG. 2.—REINFORCED CONCRETE FORMWORK TO ROOF

FIG. 3—THE REINFORCED CONCRETE RESERVOIR OF THE CEDEGOLO POWER STATION

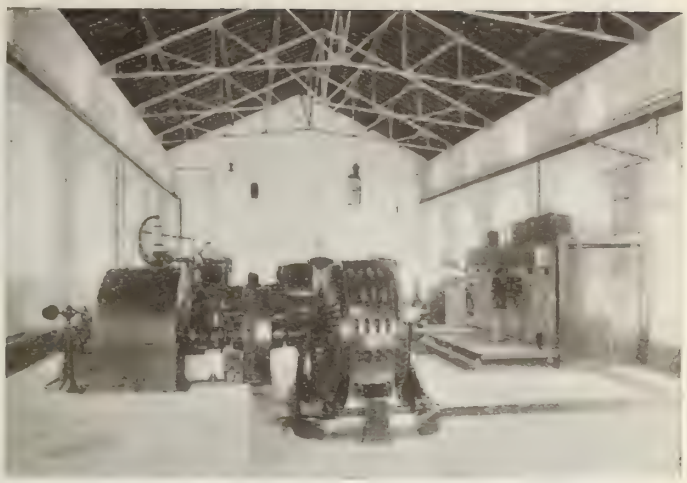

FIG. 5 PATARAS HYDRO-ELECTRIC PLANT.

an absolutely tight closing of these valves they are fitted with leather rings protected by bronze liners against the wearing action of the quickly moving water.

The turbines are of the Pelton wheel type. The smaller wheel has a mean diameter of about 5 feet 5 inches and is that employed in the 3,000 horsepower turbine. The larger Pelton wheel has a mean diameter of about 9 feet 6 inches and is used in the 1,300 horsepower unit.

The generator attached to the larger powered unit has an output of 2,080 kilovolt-amperes at 42 periods. In the case of the smaller powered unit there is a 1,000-kilovolt-ampere 42 period generator at one end and a 500-kilovolt-ampere 48-period generator at the other.

The 3,000 horsepower unit runs at 630 revolutions per minute, the other at 360. The load on the station is fairly even and is not liable to large and sudden changes. This fact and the installation of a particularly accurate regulating mechanism, to be described shortly, has enabled the turbine makers to dispense with fly-wheels in the design of the Pelton wheels. Such fly-wheels would in ordinary circumstances be more or less essential for good regulation with pipe lines more than one and a quarter miles in length.

In the case of the 3,000 horsepower unit it has thus been possible to fix the Pelton wheel direct to the end of the generator shaft, which for this reason is provided with an extra large bearing on the turbine side. At the Lontsch Power Station 6,800 horsepower units are in use. The advantages of it are said to be considerable. For example, not only is space saved but there are only two bearings to be kept in alignment instead of four.

In the case of the 3,000 horsepower unit a disc of forged steel carrying the buckets at its periphery is bolted to the flanged end of the generator shaft. The buckets are of a special steel and are highly polished over their concave faces.

FIG. 4—REINFORCED CONCRETE HYDRAULIC INSTALLATION OF THE CEDEGOLO POWER STATION

The housing of the Pelton wheel and its governor is bolted to the bed-plate of the generator. At its lower part it is arched and splayed out so that the water after discharge from the buckets may be guided in a gentle curve into the tail race. A short shaft coupled to the outer face of the wheel disc and carried in a bearing on the housing drives the pendulum governor through two pairs of bevels. The water is led to the wheel through a cast steel bend securely fixed to the foundations. The nozzle at the end of this bend is made detachable for renewal or repairs, and when full open gives a horizontal jet about 2⅜ inches in diameter.

The area of the nozzle is adjusted by a knob and needle in the usual way, the movement being effected by oil pressure under the control of the governor. As the head utilized is 2,800 feet and the pipe line is over one and a quarter miles in length, special attention has been devoted to the design of the governing arrangements. The governor to be effective must answer quickly and must keep the speed constant or very nearly so, even when the load changes suddenly and by a large amount. The contract condition on this matter was that the throwing off of the whole load, as would occur, for example, in the event of a short circuit, should not cause the speed to increase by more than 8 per cent. above the normal.

The main difficulties to be overcome were two in number as any sudden partial or complete closing of the nozzle would create an excess of pressure which would react on the regulating means with a tendency to increase the speed rather than diminish it. Again, the same sudden closing of the nozzle would lay the pipe lines open to the dangers arising from water hammer. The deflecting nozzle arrangement so frequently adopted whereby part or the whole of the jet is, on the occurrence of a sudden and great change of load, turned temporarily to one side of the wheel was not thought to be a good solution in the present instance.

It was pointed out that if no arrangements were made simultaneously to close the nozzle the method would be wasteful. Further, the mechanism required would

FIG. 6

soon become leaky and require frequent repairing. The impingement of the jet, at a wrong angle on the buckets, causes rapid wear to take place at their tips. The pressure regulator which automatically opens and by-passes some of the water as soon as the turbine speed increases was regarded as favorable, but was not considered farther, on the ground that under high pressures especially it is difficult to keep the device water-tight.

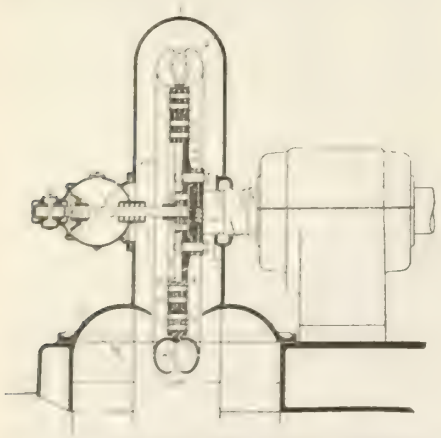

FIG. ARMBERG HYDRAULIC TURBINE. CROSS SECTION.

The arrangement adopted is illustrated in drawing Fig. 11. It consists of a double spring pendulum governor A B acting on two levers C D fulcrumed at E and F respectively. The fulcrum E is carried by a bar G joined at one end to an eccentric H and at the other to a vertical rod J. The fulcrum F is carried by the rod J. The lever D is connected to an oil brake or dashpot K which prevents it moving otherwise than slowly The levers C and D control the regulating valves L M respectively. The valve L operates the servo-motor N which servo-motor controls the position of a deflector P working in conjunction with a fixed bend Q down which water can pass to the tail race. The valve M operates the servo-motor R controlling the position of the needle valve S. When the turbine for any reason changes its speed slowly the levers C and D are moved by the governors in unison as the dashpot K under these circumstances exerts no restraint on the lever D.

The needle valve S and the deflector P are thus moved simultaneously, the proportion of the parts being such that the movement of the deflector always brings it finally into a position tangential to the jet. In other words, if the needle valve increase or decrease the area of the jet the deflector will move simultaneously into such a position that its upper tip is almost, but not quite, cutting into the lower surface of the jet. If, now, the speed of the turbine increases quickly, the levers C and D move in a different ratio, for the dashpot K prevents the lever D from moving other than slowly. The result is that the deflector P cuts into the jet and spills a portion of it down the pipe Q to the tail race.

The needle valve S is meanwhile slowly closing the orifice. When the size of jet proper to the reduced load has been established by the movement of the needle valve the necessity for spilling part of the water down the pipe Q is over, and the deflector P, through the agency of the rod T, the rod J, the lever G and the eccentric H, is once more brought tangential to the new size of the jet.

By this arrangement there was involved very little waste of water, the buckets

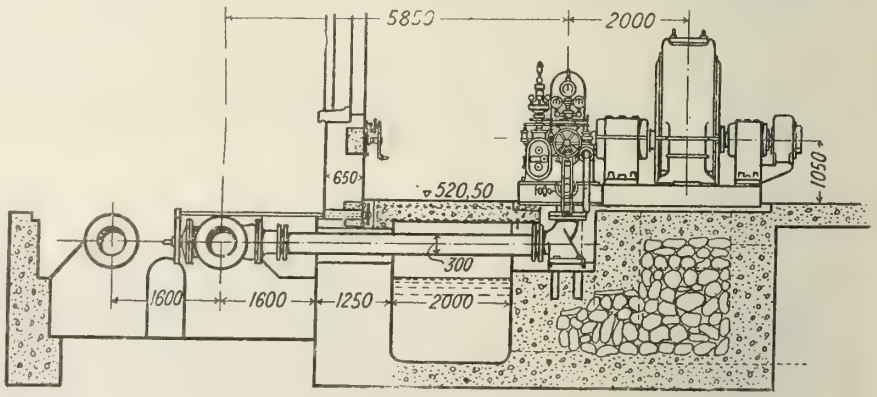

FIG. 8—ARMBERG HYDRO-ELECTRIC UNIT OF 13,000 H.P. CAPACITY

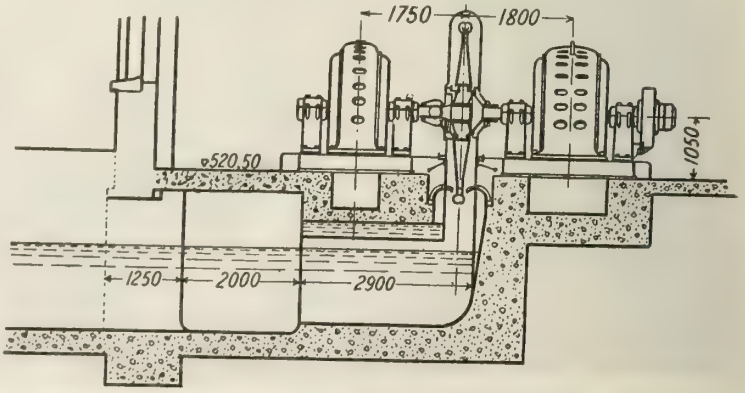

FIG. 9—3,000 H.P. UNIT OF ARMBERG HYDRO-ELECTRIC PLANT. DIMENSIONS ARE IN MILLIMETERS.

were not subjected to the action of a deflected jet, while the flow in the pipe line was reduced slowly by the action of the needle valve although the actual governing of the wheel is by the action of the deflector quite sharp. The pressure required for moving the pistons of the servomotors was obtained from a rotary oil pump driven off the same shaft as the governor.

The design of the 1,300 horsepower turbine was similar to that of the 3,000 horsepower unit. The boss of the Pelton wheel in this case was keyed [illegible] end of one generator shaft and on the other side carries a flange to which the shaft of the second generator was coupled. The turbines at Arniberg were designed at Kriens, Switzerland, where the 15,000 horse-power turbine was developed to work under a fall of 1,180 feet at the Lontsch Power Station. With the six 6,800 horsepower turbines installed at this station the capacity at Lontsch is now more than 55,000 horsepower.

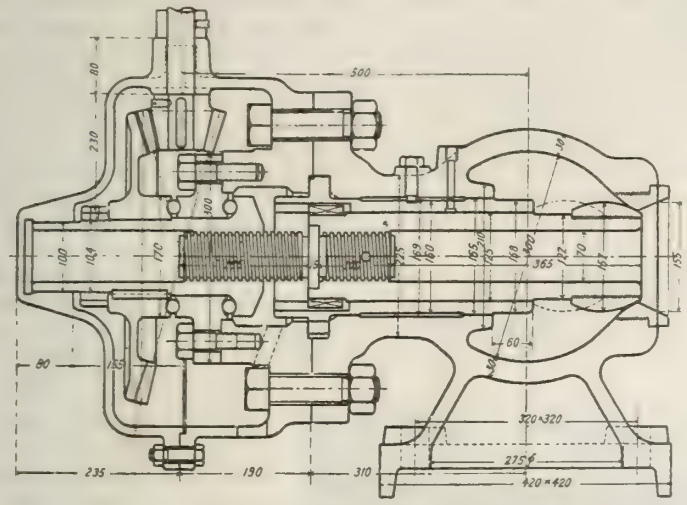

FIG. 10—REGULATING VALVE

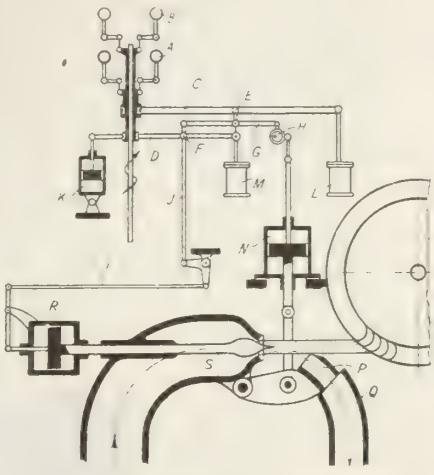

FIG. 11—DIAGRAM OF GOVERNING ENGINEER

SMOKE PREVENTION—COAL SAVING SUGGESTIONS

Just at this time when the conservation of coal is an absolute necessity and every practical suggestion for such conservation is a shot at our enemy, everyone realizes that smoke issuing from boiler stacks represents unused heat units, but everyone does not realize thot certain simple rules, if observed in the fire room, will materially decrease this loss. The suggestions herein are based on many years' experience of the Westinghouse Electric & Mfg. Company's combustion engineers and are briefly outlined below.

1. Give your fireman an opportunity to acquire the fundamental principles of fuel burning.

2. If you have a difficult fuel problem, consult a combustion engineer.

3. Prevent smoke by proper firing methods.

4. Use gauges to indicate exactly the condition of fire bed at all times. As a minimum these gauges shoulld consist of draft gauge indicating draft in furnace above fuel bed, draft gauge indicating draft at boiler side of flue damper and a steam flow meter for individual boilers.

5. CO_2 is the principle product of complete combustion of coal. Ten to twelve per cent CO_2 should be obtained in flue gases to insure minimum fuel loss.

6. Avoid loss due to unburned coal in the ash.

7. If you are wasting exhaust steam you are wasting coal.

8. Do not permit grates to clog. A systematic method of keeping the air spaces clean must be followed.

9. Inspect the baffles in boilers as broken or leaky baffles raise the flue gas temperature and waste coal.

10. Avoid leaking in of cold air around boiler setting.

11. Install stokers. Hand firing is rapidly being recognized as an absolute and wasteful method of firing.

12. Clean scale from tubes, as every particle of scale represents wasted coal

13. Avoid soot formation. All boiler tubes should be blown externally once every eight hours when in continuous service.

14. All smoke flues should be as short and straight as possible. Flues should also be made air tight and all joints and connections should be well fitted, caulked and riveted. Use asbestos gaskets on clean-out doors.

15. Locate flue dampers in front of boiler so that fireman will adjust them as required. Dampers located in rear of boilers are seldom disturbed regardless of conditions.

16. The size of coal has much to do with capacity and efficiency of boilers. In general, the air pressure penetrates the fuel bed formed by coarse coal easier than that formed by finer coal, resulting in disturbance of best furnace conditions.

In addition to the above suggestions the following "don't fail to do" list should be followed:

Don't fail to:—

Keep the heating surfaces of the boilers free from soot, scale or oil.

Keep the fires level and free from holes.

Do not carry the fires so thin as to draw a lot of excess air through.

Do not carry the fires so thick as to have incomplete combustion of the coal.

Do not soak the coal with water before firing.

Be sure the blow-off valves do not leak.

Do not have the safety valve popping off continually.

Cover steam pipes.

Do not waste steam through leaky valves or traps.

Never use live steam if exhaust steam is available and can be used as well.

An observance of the foregoing simple rules and suggestions should materially reduce the coal consumption of the average plant.

THE JITNEY CAR AND THE POWER PLANT

By N. G. Near.

Right now the jitney car is becoming very popular in the automobile field in spite of the fact that in some cities where used 50 per cent. of the owners fail to make them pay.

Why are 50 per cent. successful and 50 per cent. unsuccessful?

It is much like the power plant problems. Sink the question deep into your mind and think it out.

Does it not seem that the personal factor enters very largely in running a jitney car and a power plant? Business sense, judgment and mechanical ability are required to succeed where others fail. Hence the reports we read from time to time of isolated plant successes alongside of plants of the same size that prove to be uneconomical. The unbusinesslike engineer must give way to the central station or to the engineer who "understands" and who can "do things."

IN Japan, the government and the manufacturers are jointly spending $2,000,000 on an Institute for Physical and Chemical Research.

Why We Are Asked to Conserve Ammonia

Ammonia Being One of the Nitrogen Compounds, Plays a Very Essential Part in Modern Warfare, Even Though Its Connection is Not Apparent at First Sight

By W. F. SUTHERLAND, Associate Editor

THE engineer who has charge of a refrigerating plant knows all too well the trouble experienced in obtaining supplies of ammonia when required. This difficulty is explained when it is known that ammonia is obtained from many sources in direct competition with the production of nitric acid, so all important in the making of explosives, not only so but ammonia itself forms the basis of an extremely powerful explosive and also forms a starting point from which it is possible to form nitric acid.

The chemistry of the nitrogen compounds, to which the ammonia compounds belong, forms a very interesting chapter in the history of industrial chemistry.

A few years ago the only sources available for the production of nitric acid were the enormous deposits of nitrates in Chili and elsewhere and ammonia itself was obtained mainly from the destructive distillation of organic materials or as a by-product in the manufacture of illuminating gas and coke. Nitrogen as an element is more or less a chemically inert substance, but in the form of its many compounds is essential in the modern arts, of peace and war, and is of great importance to plant and animal life. The plant needs nitrogen compounds for its existence, the animal needs them also and obtains them through its plant food, either directly or through the other animals upon which it preys. A soil's fertility in large measure is directly proportional to the amount of fixed nitrogen present in it and when this is exhausted it is necessary to restore it by means of fertilizers either natural or artificial. Manure is valuable as a fertilizer, mainly through its large nitrogen content, mainly in the form of ammonia compounds. The Chili nitrate beds were formerly one of the largest sources of supply for Germany's artificial fertilizer requirements and since this source of supply has been cut off the results are seen in her greatly decreased food production.

THE UNITED STATES AS PART OF THEIR CAMPAIGN IN URGING THE CONSERVATION OF AMMONIA HAVE REPRODUCED THE POSTER SHOWN ABOVE. THE SIZE OF THE POSTER IS 22½ x 16½ INCHES., AND IT IS ATTRACTIVELY COLORED

Artificial Production of Nitrogen Compounds

The probable exhaustion of the world's supply of Chili saltpeter at no very distant date, estimated to be in 1940, brought attention to bear upon the possibility of the fixation of atmospheric nitrogen and several successful processes have been developed during the past few years for its accomplishment, all of them requiring much power for the carrying out of the particular process involved. The power necessary for this purpose is yet another reason for conservation of ammonia in every possible way.

The calcium cyanamide process is one of the most successful which has been developed commercially and the industry has reached an enormous size at Niagara Falls, where cheap power and other advantages are very favorable.

When a current of pure nitrogen is passed through calcium carbide at a proper temperature it is taken up and cyanamide results according to the formula,

$$Ca_2 + N_2 = CaCN_2 + C$$

or calcium carbide plus nitrogen gives calcium cyanamide and carbon.

This product was, before the war, used for fertilizing the soil, the nitrogen being given up as needed by the plants During the last few years, however, the farmer stands mighty little chance of obtaining plant food in this form, for by passing superheated steam through the cyanamide it has been found that ammonia is given off according to the formula,

$$CaCN_2 + 3H_2O = CaCO_3 + 2NH_3$$

or cyanamide plus steam gives calcium carbonate and ammonia. This ammonia in turn can be used if desired to make nitric acid and finally explosives.

Making Ammonia by the Haber Process

One of our ingenious enemies, a German, invented a process for the direct production of ammonia from nitrogen and hydrogen. It has long been known that these two gases when subject to the action of an electric spark produced ammonia, but Haber went one better and subjected them to intense heat and under high pressure in the presence of a catalyst. This resulted in the production of anhydrous ammonia.

Here one of the wily tricks of the devious Hun appeared, for fearing competition, or more likely realizing the value of many of his chemical processes to a country at war, the patent specifications covering them were made either vague or purposely misleading. This was discovered after the war started, and as expected, it cost the Allies large sums of money and considerable time to undo some of this trickery. All things have their compensations, and it's a poor rule that won't work both ways. Since the patents covering many important processes are incomplete and not being workable are invalid, anyone, therefore, is at liberty to go ahead and work many of them, and Germany is without patent protection after the war. This applies to many of the chemical processes in which Germany, before the war, had a monopoly.

Another method by which nitrogen is being won from the air is of considerable importance, but has to do with the making of nitric acid directly by means

of the intense heat of the electric arc. Several modifications of the process are in common use and it is probably by this means that Germany is obtaining most of the nitric acid needed for explosives.

Ammonia From Natural Sources

By far the largest quantity of ammonia obtained from natural sources is recovered from the waste liquors of gas works and by-product coke ovens. Coal always contains a small amount of hydrogen and nitrogen, and when distilled gives them off in combination as ammonia, which is caught in the wash water and afterwards recovered.

The distillation of animal products such as hair, hoofs, etc., is another source, while the destructive distillation of wood is a third.

Peat has received considerable attention of late owing to its possible fuel value, a consideration at present, needless to say, but it seems likely that better use may be made of some peat bogs by recovering the nitrogen which runs quite high. This is another source of ammonia and one which may prove to be quite valuable.

Modern Explosives

Nearly all the explosive compounds in actual use in the present war are nitrogen compounds and nearly all are obtained more or less directly from nitric acid. Nitroglycerine is a compound of nitric acid with glycerine; guncotton with cellulose or cotton; T.N.T., with toluol, a substance obtained from coal in the gas works or coke-oven plants. Picric acid or the English lydditte and the French melinite is formed of carbolic and nitric acids, and so it goes through the whole list of high explosives, each one of them consisting of some organic substance united with nitric acid in some particular way.

If it wasn't for the nitric acid and ammonia produced to-day the armies would have to fall back on gunpowder, almost a forgotten thing of the past. It is easily seen then that any careless waste of ammonia in the refrigerating plant means a direct loss of material, the replacement of which has a direct effect in the lengthening of the war.

The United States Fuel Administration as part of their duties have been emphasizing this fact and have brought the matter very forcibly to the attention of the plant engineers in the United States. In a message issued by them it is stated that:

During 1918, the Government should have for munitions alone 20,000,000 lb. of ammonia more than it is possible to make by working all the plants producing ammonia in the United States to their maximum capacity.

This shortage will be greatly increased by the ammonia that will be furnished ice-making and refrigerating plants, but it is hoped that by appealing to the patriotism and business sense of all ammonia users and urging them to stop all waste and leakage that the usual consumption may be curtailed to such an extent as will permit at least the most efficient plants to run; particularly where the natural ice is not available.

The returns lately received show that much ammonia loss is avoidable. Many plants use less than one-twentieth of a pound per ton of ice made; while others use from one-half to one pound per ton. The same inexcusable waste is found in many refrigerating plants. The only reason that can be given for permitting the enormous waste and expense to continue at some plants is that the management has not informed itself as to what is a reasonable consumption and the operating force is indifferent about leaks that might easily be stopped but are allowed to continue.

How to Save Ammonia

A saving of 25 per cent. in the ammonia consumption of ice and refrigerating plants would mean several million pounds annually for munitions. Each pound will make twenty hand grenades. Late returns show this saving can be accomplished if all will stop the leaks. To start an effective campaign to bring about this saving, the following urgent requests are being sent to all plants:

1. Before starting your plant (or if it is now operating) see to it that the ammonia system is tight. The slightest smell of ammonia indicates a leak which should be located and stopped at once.

2. Small leaks may be detected by burning sulphur in their presence.

3. Leaks in condensers or tanks may be traced by the use of phenolphthalein testing paper, which can be obtained from your ammonia dealer.

4. Test for leaks daily and be on the lookout for them constantly.

5. See that the pump or compressor rods are true and properly aligned, and that the stuffing-boxes are properly packed with good packing.

6. Stuffing-boxes are the source of heavy losses. When subjected to extreme changes in temperature they must be carefully adjusted and lubricated to prevent leakage or heating. Packings of proper design and material correct stuffing-box troubles.

7. Another source of leak is the pitting or roughening of infrequently used valve stems (particularly those that are exposed to moisture) tearing the packing when they are opened or closed. This can be prevented by smoothing up the valve stems and keeping the exposed part of the stem covered with a heavy grease.

8. Care should be taken in the manipulation of expansion valves so as not to force liquid ammonia to the compressor; it will start leaks and may cause accidents.

9. Do not pump a vacuum on ammonia system unless absolutely necessary, as a vacuum tends to draw air into the system. No vacuum is necessary when charging ammonia into the system. When it is found necessary to purge the system of air, or other noncondensible gases, shut off and cool down the condenser or absorber to be purged. Do not blow direct to the atmosphere when purging, but carry the purge line close to the bottom of a receptacle containing slowly running water. Purge slowly. Noncondensible gases are indicated by bubbles rising to the surface, while a crackling sound indicates the loss of ammonia.

10 Your own business interest demands that you get every employee interested in this campaign. There is no better way to get them interested than to offer them a share of what they save.

Give Employees a Bonus

The Food Administration urges you to give a bonus offer your favorable consideration and to put it promptly before your employees. The saving may be computed by finding the difference in fractions of a pound of ammonia used per ton of ice made in 1917 and 1918. This difference times the tons of ice made in 1918 gives the total saving of ammonia in pounds, and pounds saved multiplied by cost price of ammonia gives the saving in dollars and cents.

The employees' share should be agreed upon when the campaign starts. It may be any part of the entire saving, but for this campaign 50 per cent. is recommended.

Initial charges for plants started in 1917 or losses due to accident should not be considered as ammonia consumed.

All employees (engineers, oilers, and repairmen) who assist in keeping the system tight and saving the ammonia should share in the bonus.

11. Each plant shall report on the first of each month on forms to be later furnished by the United States Food Administration, as follows: (a) Amount of ammonia in the system when it is fully charged; (b) amount of ammonia put in during the past month; (c) amount that will probably be required for the present month; (d) ice made during the past month; (e) average daily refrigerating duty (in tons refrigeration) during past month (aside from ice making); (f) manufacturer furnishing ammonia; (g) if you have had excessive ammonia lost state cause; (h) state the amount of uncharged ammonia on hand. Have you adopted a bonus system?

What Are You Doing Towards It?

In view of what is being done in the United States is it too much to ask that those in authority here should take a more lively interest in the conservation of, well, everything from coal to ammonia? And in the meantime, Mr. Plant Owner and Operating Engineer, what are you doing towards the winning of the war in your own power plant?

Tight Boiler Settings An Aid to Economy

Author Cites Instances Coming Under His Own Observation and Discusses Practical Means For Securing Air-tightness

By J. E. McCORMACK

IN the immediate future when colder months are approaching, and the outside air which we use for draft absorbs more B. T. U. before reaching uptake temperature; the importance of having a minimum of air leakage through our boiler settings becomes of more moment. As it is only a few years since engineers began to properly appreciate the practical signficance of even small air leaks in boiler settings there may yet be some who do not fully realize their gravity.

I will cite two extreme instances which have come under my own observation. The first was that of a single boiler installed too late in the season and portions of the masonry became frozen before becoming properly dry. When the plant was put into operation, the masonry developed unseen air leaks owing to the action of its frozen portions and the outfit was extremely hard to fire during the winter months. Four fireman each in turn were put on the job and each in turn failed to hold steam satisfactory. As the weather became warmer during the spring months, the firing became more and more easy until in the following May when one of those same four fireman was back on the job he found it "dead easy" to hold steam then. There was apparently little reason for this change except that due to the difference in outdoor temperatures.

During the summer the masonry was torn down and rebuilt and later gave satisfactory results, both in summer and in winter.

In the other instance, I had, during October, been firing for a few days on a one boiler installation and everything went O.K. Later, I was away for some time, but during late November or early December returned to this same job. Being, as I thought, already familiar with the plant, I did not examine the upper part of the setting with any care. The work was light for the engine and so I carried a thin fuel bed and a light draft and got along fine, I thought, until one day some machinery requiring more power was thrown on and as I normally would have then required more draft, I increased it accordingly. Then my thin fuel bed failed me and I increased its thickness until it was as deep as I believed was practicable even with all the available draft on, yet it "kept me guessing" to hold steam and water where I wanted them.

I soon believed I had fire enough to "roast the bottom out of her" as popular expression has it, and after sizing up the load being carried by the engine I reasoned that a fuel bed such as I had then should carry the load even without heavy draft, so I unfastened the smoke box doors and let them hang loose. This reduceed the draft, but the steam did not drop. In fact I held the steam with no more exercise of judgment and with much less fuel than when full draft was on. This of course, indicated a bad aid leak somewhere. Had there been an CO_2 recorder attached I would probably have detected by it the presence of this leak perhaps sooner. When opportunity permitted I piled onfresh fuel purposely to make black smoke then stopped off the draft so as to let the said smoke pour out through the setting if it would. The sides of the setting emitted oo smoke, but on going on top I found lots of smoke.

At the back end of the boiler where the expansion and contraction tend to push the masonry away from the boiler, there had been an opening on which had been laid a piece of small steam pipe. This probably for a time had diminished the leakage at this point, but it had gradually worked down between the boiler and the setting and finally dropped through leaving behind it an opening as wide as the pipes external diameter. Conseqneutly when I had increased the draft I had increased the amount of cold air entering at this point and according as the fuel bed had become thicker the increased resistance to air passing through it greatly increased the proportion of cold air entering at the setting and resulting in the greater waste of fuel and difficulty in holding steam. Of course, I got the leak remedied before the next day's operation. These are extreme instances. The most extreme I have come across, but probably many have had experiences which to a certain extent paralleled the above.

In this connection, three points are worthy of note. (1) The temperature of the outside air has considerable influence on the amount of waste caused by a given size of air leak. (2) The thicker the fuel bed, the more resistance there is to air passing through it and since the resistance at the point of leakage is practically uniform the proportion of air passing through the setting becomes greater accordingly as the fuel bed becomes thicker, and (3) (What is more adoptable to practical use in everyday routine). The regulation of the draft by means of a damper in the stack or in the individual uptakes or—when it is a single boiler setting—by closing or slighly opening the smoke box doors, gives less leakage or air through the setting by reducing the pressure drop at the base of the uptake, whereas, regulating the draft by use of the ash pit doors does not reduce the said pressure drop there to the same extent, therefore, air still continues to filter through the setting at near the same old rate, while by this latter practice the grates are more exposed to overheating and consequent warping. For this reason I am pleased to say that to date my witnessing of stationary boiler furnace draft being regulated chiefly by use of ash pit doors has been confined almost entirely to firemen of limited boiler room experience. A boiler of the stationary type un-equipped with with any other possible method of draft regulation being a rarity and an exception.

In many small internally fired units, such as are used for portable or traction purposes, the ash pan damper is the most used and in some cases the only available means of draft control. In such outfits the air leak problem does not intrude itself, but I have been impressed by the conspicuous necessity for grate renewals in many of these outfits and am of the opinion that draft control by a damper in the stack and accompanied by avoidance of live coals in the ash pan would result in an appreciably prolonged life to the grates in these outfits. Where there was an exhaust nozzle in the stack I would like the damper placed below the nozzle, though I have seen one used above.

During past years the U. S. A. Government has carried out experiments and investigation regarding fuels, steam plant operation, producer gas plant operation, etc. Bulletins setting forth information thus gained have been published and made procurable from the Superintendent of Documents, Government Printing Office, Washington, D. C., and at a price so low as to surely cover little more than the cost of production together with postal rates for mailing them.

Bureau of Mines Bulletin 97, entitled "Sampling and Analyzing Flue Gasses," saye on page 40, "In the majority of instances leaky settings are the cause of a low percentage of CO_2 in the flue gases This cause is harder to remove than the holes in the fires. Even a well-cared-for boiler setting allows a considerable volume of air to leak in. In the average plant probably not less than thirty per cent. of the gases passing through the uptake leaks in through the setting.

Bureau of Mines Technical paper 80, entitled "Hand Firing Soft Coal Under Power-plant Boilers" says on page 63. "The amount of air that leaks into a boiler setting between the furnace and the uptake is seldom appreciated. Even in a well-cared-for setting the leakag amounts to 25 per cent. of the gases passing through the uptake. Therefore, to reduce the excess of air, the fires should be kept from holes and the seting free from cracks and other leaks."

On page 72 the same bulletin says: "The settings of all boilers should be kept air-tight. Too frequently no attention is given this feature. It is safe to say that on the overage fully one-third of the air found in the breeching entered the boiler setting through leaks, and in bad cases twice as much air may enter through leaks as through the regular openings.

Bulletin 97 describes experiments made with a furnace and long combustion chamber connected to the setting of a Heine boiler. The products of combustion passing from this chamber into the combustion chamber of the boiler, then up the stack serving the said boiler. The products of combustion were sampled just before they entered the boiler and again at its uptake. The bulletin describes in considerable detail the sampling devices used. All samples were collected simultaneously and the time of sampling was about twenty minutes. Eight sets of samples were taken. Two analysis tabulations are given, one is of the samples taken just before entering the boiler. The other is of the samples taken in the uptake. The bulletin on page 40 says: "The setting was seemingly in good condition; all the cracks as well as the joints between metal and brick wall were carefully packed with asbestos rope and the walls were painted with thick asphalt paint. In spite of all these precautionary measures considerable air entered the setting, as a comparison of the average values of the two tables shows. No serious objection can be made against the method of sampling the gases. Both sets of samples were collected simultaneously." With a view to ascertaining the percentage of air which really had leaked in through the setting I made calculations from the averages given in the respective tabulations, and, considering the condition of the setting as described, the result I obtained is agreeable with bulletin statements, that in general practice 25 per cent. to 33 per cent. of the air to be found in the uptake may have leaked in through the setting. Bureau of Mines Bulletin 23, entitled "Steaming Tests of Coals and Related Investigations," says on page 289: "The air entering the furnace through the small openings and cracks in the firing doors is useful, and is to a great exent necessary for the complete combustion of the gases and tar vapors leaving the fuel bed; in fact, air entering the furnace through any opening in the walls may be of some benefit for the combustion of the fuel, and therefore, need not be always regarded as harmful. But the air entering the boiler setting beyond the furnace where no combustion is taking place is always detrimental to good economy inasmuch as it lowers the temperature of the products of combustion, thus making less heat available for absorption by the boiler. All brick settings are more or less leaky, and, even if well cared for and the cracks constantly patched, there will be a considerable air leakage into the boiler setting.

At the fuel-testing plant at St. Louis, Mo., a man was constantly employed to patch up the leaks in the settings of the boilers, nevertheless, considerable leakage was shown by the analysis of the flue-gas samples collected at different places."

In one instance mentioned samples were collected—one set at the base of the stack, and another at the rear of the combustion chamber. The time of collection was thirty minutes and the samples were taken simultaneously. The object was to determine the leakage of air between the place where the gases leave the combustion chamber and the place where they leave the setting. The indications were that of the air supply shown by the gas composition at the base of the stack about 26 per cent. leaked in after the gases left the furnace. On page 290 the bulletin says: "This large air leakage makes it imperative that if the information obtained from the gas analyses is to be of any value in controlling the fire, the gas samples should be collected at some place before they are diluted by leakage. (Right here it might be well to note that as has been pointed out by Breckenridge, a high percentage of CO_2 is not necessarily an indication of high economy. When the air supply is reduced, the furnace temperature, CO_2, CO, and smoke are all increased after a certain capacity is reached. This may give a hint regarding difficulty of securing satisfying results when firing to secure a good CO_2 reading while the instrument is getting its samples from air diluted gases effected by leaks in the setting.) Referring again to the condition of the settings of the boilers in connection with which aforementioned experiments were conducted, I will quote from Bulletin 23, page 291, as follows: "All the walls were painted two or three times with thick barn paint and a man spent daily four or five hours in patching the cracks or otherwise reducing the infiltration of air, so that the leakage shown in the preceding discussion is perhaps smaller than that in the average steam plant."

I quote this by way of giving further emphasis to the advisability of giving frequent attention to the condition of the boiler settings, especially those portions to the rear of the bridge wall.

Concerning the method of draft control as effecting the air leak problem, I quote from technical paper 80, page 24, as follows: "Figure II. is intended to show air entering the furnace and setting in three streams, one through the ash pit door, another through the openings in the fire doors, and a third, which is found in most furnaces, through leaks in the furnace and setting. Only one way, the uptake, is provided for the gases leaving the setting. It is evident that when the damper in the uptake is partly closed the air entering in all three of the ways named is reduced in the same proportion and the total air supply per pound of coal consumed remains nearly constant. On the other hand, if the ash pit door is partly closed only the amount of air entering the furnace through the fuel bed is reduced, and the amount entering through the furnace door and the leaks is increased because of the higher draft in the furnace. For these reasons regulation of the draft with ash-pit doors is objectionable and should be avoided."

It is also obvious that where draft is secured by mechanically operated fans, a combustion of forced draft and of induced draft so proportioned as to give as nearly as possible a uniform air pressure on the two sides (inside and outside) of the setting walls at the rear of the bridge will greatly reduce the effect of air leaks here as compare with either induced or forced draft employed alone, though of course it is not every plant that could conveniently and profitably be so equipped.

DRY AND WET COAL

The effect upon the efficiency of a boiler when using wet and dry coal has not been definitely known, according to J. J. Light, instructor in mechanical engineering, in Bulletin No. 22 of the Engineering Experiment Station of the Pennsylvania State College. Among coal users, especially those operating house-heating boilers, there is a wide difference of opinion as to the relative merits of the practice of wetting the coal before firing. The object of a series of 10 tests tabulated was to show the efficiency of a house-heating plant when fired with coal that has been made wet, and with coal as usually found in cellars of residences, which can be considered as practically dry.

Since two series of tests were run under the same conditions except for moisture of the coal, it is possible to obtain information as to the benefits derived in house heating by firing either dry or wet coal. The conclusion is that the common inference that an addition of water to the coal as fired is beneficial to the operation of the furnace seems false.

The tests from which the results were obtained were in charge of an experienced fireman, who had very strong convictions, from his practical experience, that moistening the coal was a decided commercial advantage in the operation of boiler plants, which fact would in all probability produce an error in favor of wet coal provided any error was introduced.

The item, equivalent evaporation from and at 212 deg. Fahr. per pound of combustible, and the item, efficiency of the furnace, are two factors which would appear to decide the relative merits of the wet and dry coal. It developed throughout the tests that one pound of combustible evaporates more when the coal is fired dry or as is ordinarily found in cellars of residences than when it is purposely moistened. The efficiency of the furnace throughout the tests showed that wet coal tends to decrease rather than increase operating economy.

From a theoretical point of view the addition of water to the coal is a decided loss and would probably be equal to the heat required to evaporate the water added, from the room temperature into steam at a temperature corresponding to the flue gas under the pressure as maintained in the flue. It is the opinion of those who are believers in moistening the coal that the addition of water aids in the complete combustion of the volatile hydrocarbons. This fact probably cannot be disputed, but the tests showed that the gain due to complete combustion is less than the heat carried away by the water."

Interconnection Will Help Coal Situation

Shortage of Fuel—Necessity for Saving—Interconnection of Many Isolated Plants With Central Station Feasible and Would Result in Material Saving of Fuel

THIS is a subject which is foremost in the minds of most of the adult population of Canada, irrespective of sex, creed or profession, but to engineers especially it is one of vital (and I use the word advisedly) interest. During the past two winters Central Canada at least has suffered from a shortage of coal, and many and various have been the expedients adopted and suggested to relieve the inconvenience and in some cases actual suffering which the shortage has entailed. Now from all visible signs the coming winter will most likely see a further shortage of coal, and by this is meant that the coal will actually not be mined. Undoubtedly mine owners and operators and the railway companies will come in for their share in the wholesale condemnation, which is bound to come from an indignant public. But since the coal will not be forthcoming. Nothing remains to be done but to make the best of a bad job and get the most work (or heat) out of the amount that we do get. Hence the title of this article.

Now as the writer sees it conservation of coal does not just mean to be careful of the coal that is supplied to one's own plant, that is the individual view, but this question is one of national importance and should be viewed from a national viewpoint, so that the idea of conservation is not merely to conserve one's own coal, but also that of everyone else. Now this at first sight may seem ridiculous, but really it is not. If the engineer in one plant is careful of his own coal only, but allows oil or other supplies to be used, if not wastefully, in larger quantities than is absolutely necessary, he is causing the nation's coal to be used to make those supplies, which might have been saved by greater care.

So that conservation of coal means to an engineer using everything about the power plant to the utmost limit of efficiency.

Conservation of resources is at any time commendable, but under present industrial and national conditions it is a duty which devolves upon every one who claims to be at least patriotic.

Central Canada is entirely dependent upon the goodwill of the people of the United States for coal, and Eastern and Western Canada to a less extent. Now it cannot be expected that Canada will obtain more favored treatment than any one of the States of the Union, one does not feed strangers, or even friends, before one's family, so that if the U. S. is short of coal, Canada must of necessity be also.

Perhaps a word of explanation as to the wherefore of the coal shortage might not be out of place at this juncture.

The writer had the privilege of attending the N.A.S.E. national convention at Cincinnati last month, and at one of the meetings this question was very thoroughly ventilated and discussed. Every one present, including the writer, left the meeting impressed with a deeper sense of obligation to his employer, his country and the men who are fighting in his defence. One of the speakers, Mr. P. B. Noyes of the U. S. Fuel Administration said:—

"It is estimated that the needs of the war call for at least 100,000,000 tons more coal this year than in 1917 and 200,000,000 tons in excess of that provided in 1914, the year the war started. As figures, this does not sound difficult, but when considered that this must be produced with less man power and a railway system very little improved since the war started and taxed with inconceivably large demands from every war-making department, and when we picture this coal as being 4-5ths as much as was excavated during the sixteen years of the building of the Panama Canal, you will realize we have a problem out of range of any other.

"These war needs must be met with the most intensive work in three directions: First, the increase of production; second, through conservation; and third, by a distribution system which shall insure against "lost-motion" which shall fit our cloth exactly to our pattern.

"The Fuel Adminstration has been putting its most intensive work on increasing the production. This is evidenced by the fact that while every European country has decreased in production since the war began, the United States mined fifty million tons more coal during its first year of the war and will increase that by another fifty million tons this year.

"In almost every other line of activity the enterprise and energy of America is looked to make good, no matter what the figures. Coal alone is of too huge bulk to be increased to any extent quickly. You must remember that 52 per cent. of all railway cars loaded with coal, a tonnage equal to the great cotton crop of the United States, is moved every 1 1-3rd days; every eight days we are mining and transporting as great a weight of coal as the entire wheat crop of the United States. Our miners go deep into the earth and painfully bring up a tonnage of coal, and our railways transport it at an average of 300 miles every year, equivalent to 2¼ Panama Canals. We have fewer men in the coal mines than two years ago and will mine 100,000,000 more tons than then.

"The Conservation Bureau has organized, as you know, power, light and fuel conservation, going into every industry in the United States in addition to intensive work on domestic consumption. The figures coming in already are very encouraging. We have set a quota of 35 million tons to be saved in the boiler and power houses of industry and 15 million tons in the homes. If this can be accomplished the gap between our increased production and the much greater increase of demand will be filled.

Distribution is perhaps organized in the Fuel Adminstration more thoroughly than any other part of the work. Every week the distribution department lays on Mr. Garfield's desk a statement by districts, by states and as a nation, showing the amount of coal produced the week before in all of the 10,000 or more mines, also a statement of the amount consumed taken from the postal card reports with which you are familiar, and lastly, a statement of the amount of coal on hand, adding together the stock piles of every industry and every dealer in the country. With this information the streams of coal can be directed intelligently, can be shifted from time to time and made all the work permitted by the coal mined.

"But in the present crisis of the war with success depending upon steel, and steel depending upon coal, no ingenuity, rules or efficient adminstration will save us without practically 100 per cent. cooperation from the people of the country.

"We sometimes complain that the business men give us only a part of the cooperation we should have, that their attention is still divided by personal interests. I have found, however, in a year's association with the business interests that it is only necessary that men like yourselves should know what we know in Washington—should see the meaning of a shortage of coal as I see it every day in my connection with the War Industries Board—to get a cooperation which will ask only that it be told what sacrifice will really help.

"On March 21 Germany taught the world a new military science—that an overpowering weight of munitions and shells, guns, tanks, airplanes, etc., will bring success with a minimum of casualities. Germany got together a supply of all these munitions beyond anything the world had ever seen before. The Allies have profited by this experience. Guns, shells and everything else contributing to the saving of lives are being forwarded to France in unbeleivable quantities. The programme is founded on demonstrated fact that if you have shells to waste lives can be saved. From now on it is munitions against casualities.

"If you keep this in mind you will

have the background for the sternly drastic attitude of the Government during the next six months in clearing the way for filling Pershing's orders.

"Gentlemen, we are facing a catastrophe. It is not one of those catastrophes which makes such a noise that everyone knows when it happens. It is a silent tragedy. We cannot fill Pershing's orders in full because the United States cannot make sufficient steel this winter. Keep in mind and then look forward to the events of the coming spring. We shall have the drive. We shall succeed in it, but sometime in February or March, or whenever the time has come, Gen. Pershing will sit down with a pencil in hand, will figure up the exact deficit in the filling of his order for munitions. With military formulas now well recognized he will figure in place of those munitions how many extra men must be put into the battle to be killed. This is no fanciful statement. It is now possible to treat, in any aggressive movement, the question of munitions or of casualties as interchangeable quantities. So many thousand American youths must be thrown into the hopper for every thousand tons of munitions which are short.

With this background I know that discussion with any men present of wastage of coal or of coal to be used for any industrial or economic consideration would be very one-sided. You will go just as far as any of us in Washington in urging that no consideration be given to any economic compromise with the coal supply which balances civil prosperity against men's lives.

This statement of the case sounds tragic, but the worst of it is that it is terribly true, so true that I feel confident if every American business could see the actual facts as they come to us in Washington, there would be no need of regulations or rules, only directions. No man here would spare himself either labor to save the last pound of waste or the sacrifice involved in devoting the fuel and material he needs most in helping to complete the Pershing programme.

This will explain why a coal shortage is inevitable, and why coal conservation is a thing of national importance. What is true of the U. S. military program will fit Canada also.

The call for conservation may also be interpreted as a call for greater co-operation. This is no time for any class of people, be they representing capital or labor, to adopt any attitude or policy which will tend to reduce or slow up production in any shape or form. This country in common with all the Allied countries has one task ahead of it, "To win this war." To do this the men who have gone "over there" have done and are doing their share, so that it remains for those who are "over here" to see to it that they "carry on" and do their utmost to support those at the front. It must never be said that those who stayed behind failed in their duty to those who went overseas.

Those who are "over there" are in duty bound to co-operate, from general to buck private, and co-operation in conservation is the duty of every man and woman remaining here.

Conservation of fuel then is not a task for the engineer only but for everyone who has any interest whatever in this greatest of all world struggles. There is nothing that is required by the soldier but what is dependent upon fuel for its production and transportation. The Canadian and U. S. Governments have recently asked for gasless Sundays, and generally speaking their requests have been complied with. One reason, in the writer's opinion for this general compliance, is that the public has been told why. It is also the writer's opinion that if the public be told why all fuel should be conserved, irrespective of its kind, price or scarcity the public will heartily co-operate with the conservation boards.

Quoting from the general plans of the U. S. Fuel Administration, the writer notes the following ideas:

1. Elimination of uneconomical isolated plants.
2. The application of the skip-stop to railways and the regulation of car heating and lighting.
3. Economy in utilization of power and light in factories.
4. Utilization of excess water power and interconnection of power systems.
5. Limiting the production of power to the most efficient plants available.
6. Economy in the refrigerating and ice manufacturing industry.

Taking the first idea—to eliminate uneconomical isolated plants. This seems a drastic measure at first sight, but bearing in mind the great need for conservation, it will bear close examination. The Fuel Administration state that it is not their intention to impose any hardship upon the public, but that in many cases power can be supplied from the central station at a less expenditure of fuel than is the case with the isolated plant. This may or may not be so.

If there is a great demand for exhaust steam (or low pressure live steam) for either heating or process work, just the reverse to the above paragraph may be the case. If all the exhaust steam from the engines is utilized, central station power would not save the nation's coal, but to the contrary, more coal would be needed.

If the first and fourth ideas are combined coal might very readily be saved. There are many plants, electrically operated from an isolated power plant, which have use for all the exhaust steam (in Winter) for heating and in fact in many cases the exhaust steam is insufficient and large quantities of live steam are required to supply the heating demands. Many of these plants could be shut down to advantage in the summer and their machinery operated by central station current, with a material saving to the owner (by getting a low summer rate for power), to the power company (by having customers for power when the lighting load is light) and to the nation by saving coal, and the last is the most important at any rate, at present.

But in winter conditions are different. The central station has all the load that it desires, and very often more. The manufacturing plant is needing steam for heating, more than the engines are using. So that if the isolated plant could be connected to the central station lines, in many cases it could furnish power to the central station at a lower fuel cost (to the nation) than the central station itself can.

To take a definite example, the writer knows of four isolated plants within a quarter of a mile, which could amongst the four, in cold weather, supply 1,000 horsepower 24 hours per day and not notice the increased fuel consumption (if there were such). These four plants close down their generating plants for six months a year and run on central station current, to the satisfaction of both central station and plant owners.

One of the four has a live steam load of about 100 h.p., in cold weather a heating load of about 400 h.p. and an electric load of about 60 h.p. and has a generating plant of 250 h.p. It can readily be seen that this plant could furnish anything from 50 to 200 h.p. in cold weather without increasing its fuel bill, and this would save coal equivalent to that amount of power at the central station.

The question of profit or loss is only a secondary consideration to the fuel conservation board.

The Hydro-Electric System of Toronto is at present heavily overloaded, so much so that street lighting is reduced to a minimum and on dull days (and sometimes on other days) it has been found necessary to cut out some of the load in order that munition plants may have sufficient power. The Toronto Electric Light Co. is operating its steam plant up to 16,000 K.W. on the order of the Fuel Controller, and the writer was informed on good authority that this current is entirely for munition work. If all this power is necessary and we are compelled to believe that it is, surely a scheme that will release more power without increasing the fuel bill, is worthy of consideration, especially one which can be made to benefit all its participants.

There is another method by which coal can be saved and that is by paying more attention to electric lighting. Give ample light where it is needed, but turn out the lights where they are not needed.

There is another method of eliminating the uneconomical isolated plant, and that is to make it economical.

One of the slogans of the U. S. Fuel Administration is "Save the shovelful, the tons will look after themselves."

By close attention to details in the plant it may be changed from uneconomical to economical. But one thing which is fairly general should be changed before efficiency can be general, and that is the attitude of the average owner towards his power plant and its engineer. Many manufacturers look upon the power plant

and engineer as necessary evils, and treat them accordingly, instead of realizing that the power plant is one of the biggest factors towards successful business or otherwise according to the way it is operated. The man who buys the coal and the man who burns it need to get in closer touch, and both need to feel that they have an interest in the efficient operation of the power plant. In a good many cases if the wheels continue to turn when required to, it is considered quite sufficient; but the scarcity of coal with its accompanying increase of price will most likely cause some change in this attitude.

It is generally conceded that 90 per cent. of the savings to be effected in a power plant are to be made in the boiler room. That is most of the savings are to be made in the generation of steam even though there may be considerable saving effected in the use of steam.

One of the largest single causes of loss in boiler plants is in filtration of air through the brickwork of the boilers. This loss goes on hour after hour, unseen but nevertheless present. To prevent this the brickwork should be gone over with a lighted candle or other open flame and any cracks made up; this done the whole brickwork should be coated with some preparation to prevent air leaks. There are many preparations on the market.

Leaky blow-off valves, and other valves, all add the loss of efficiency. Poor grates —and this is one of the things that until recently the average owner seemed to think an extravagance—is another. So is bare pipe

The U. S. Fuel Administration has engaged a State Fuel Engineer in each State to travel from plant to plant, at the invitation of the owner, to help to increase the efficiency of the plants. I heard one of these engineers address the convention at Cincinnati, and he told us that in many cases the owner scarcely knew the way to the boiler room.. The engineer's criticisms are constructive; often he tells the engineer or firemen how to get better results, and often he tells the owner things that the plant engineer has been telling the owner, but could get no attention paid to. The idea works out well for all parties concerned. The plant owner or manager gets better acquainted with the man in overalls who keeps the wheels turning and quite often they find that they have interests in common which they did not know before. The writer remembers having occasion to use the boiler inspector in a similar manner, that is to recommend the purchase of different pieces of apparatus which the owner thought unnecessary but which afterwards proved to be good investments.

To help out during this present coal and industrial crisis the C. A. S. E. has offered the services of its members to the Canadian Manufacturers' Association to help solve any power plant problems they may have, provided that their own plants are not neglected. In this connection it is the writer's opinion that a travelling advisory engineer employed by the C.M.A. would be another method of helping to save the coal pile. The railway companies employ superintendents of power plants for the same reason, and presumably it is a paying venture or it would not be continued. It is human nature to do one's work a little better, if one knows that the work will come under inspection.

In the beginning of this article it was stated that fuel conservation was the duty of every patriotic man and woman.

The engineer may do all that science can teach, to utilize the fuel to best advantage, and with the highest efficiency but, if the products of the fuel are not used efficiently then the engineer's efforts go for naught. For example in heating, say public buildings, the usual temperature required has been 70° F, 68° F at the lowest. Quite often the writer has seen temperatures above this figure, and no attempt made by the occupants of the rooms to regulate the temperature, or if any attempt were made it would be by opening windows wide, and still leaving full steam on the radiators. Further, rooms unoccupied for hours daily, that is bedrooms, left with steam full on the radiators, window and transom wide open, and a strong wind blowing in winter, under the plea of ventilating the rooms. Leaving windows open is bad enough, but to have window and transom open and having a strong current of air blowing clear through the building is infinitely worse, and under present conditions nothing short of criminal.

So here is one way in which everyone can conserve coal; have the temperature of the rooms kept at 55° and get accustomed to it. Wear heavier clothing and get the air moister as it has been proved repeatedly that moist air gives a feeling of greater warmth, besides being healthier.

The Fuel Conservation Board recommends amongst other things having fewer stops in the street car service. Anyone who has investigated the subject, or made any tests on the starting and running currents of motors will readily see a method of saving considerable power by this method. For example, the writer in making tests on some motors found that one 10 h.p. elevator motor took nearly 30 h.p. to start, and only 3 h.p. when at full speed, and in street railway work the results are similar so that reducing the number of stops will result in saving fuel.

In public buildings and office buildings there is generally a waste of water both cold and hot, unless self-closing faucets are used and even these are not always satisfactory. Right here is another chance to economize, make sure the water is shut off properly. Water takes coal, both to pump and to heat it.

The U. S. Fuel Administration proposes to carry out its conservation plans, through the co-operation of the following:

1. A force of engineers organized and stationed with the Fuel Administration at Washington.

2. The Engineering Department of the U. S. Geological Survey.

3. The Power Division of the Council of National Defence.

4. A State Fuel Engineer attached to the office of the State Fuel Administration, to supervise the activities of his State.

5. The Public Service Commissioner and State Regulatory Bodies.

6. The Chambers of Commerce and similar representative business bodies.

7. Volunteer engineers located throughout the country.

The writer's opinion of the fuel question as formed by the lectures attended at the N. A. S. E. Convention were: That the question of fuel production and conservation is a vital one and one that every man and woman in the country is or should be interested in, and secondly that the leaders of the U. S. people realized its magnitude and seriousness and were bending every effort to cope with it, and also that the leaders realized that without the co-operation of all the engineers and firemen, the work of the Administration would go for naught. Also that the desired co-operation would not be wanting if the feeling of the above meeting were to be taken as a criterion.

If the U. S. can get co-operation between its Fuel Controller and fuel consumers, why cannot Canada? If Canada has a Fuel Administration it is nearly time that it got very busy.

BENDING CAST IRON PIPES

By M. E.

A successful bending of large straight cast iron pipes was recently effected in making the line of cast iron pipe which it had been decided to lay to convey water from the Guayabo River to the town of Present, Cuba. By mistake no sleeves or curves had been ordered. The canyon through which the pipe passes for a distance of about two miles from the dam is crooked, making impossible such easy curves as would be made in the pipe joints. As it might have taken several months to secure additional special pipes, the local engineer decided to bend some of the straight cast iron pipes. The Cuban workers had frequently bent steel or wrought iron pipes at their sugar mills, and they followed the same course of procedure with the cast pipes, with entire success, as they did not break or spoil a single pipe. The pipes were bent to various radii, the shortest being 50 feet. A cradle of old rails was first constructed with the desired amount of curvature, and a fire of hardwood was built under and around the pipes. Six or eight pipes were bent at a time. In one and a half or two hours after starting the fires, the pipes were hot enough to bend and settle under their own weight on to the cradle prepared for them. The pipes were 10 in. in diameter with 9-16 in. thickness of shell, their weight being about 760 lb per 12 feet length.

The United States Fuel Administration announces that manufacturers of incandescent electric light bulbs, by agreeing to limit the production of lights having carbon filaments and substituting them with the more efficient metallic filament types, have made possible a saving of one million tons of coal annually.

KEEPING BOILER TUBES FREE FROM SOOT

By W. Saller

SINCE the tubes of a boiler are the medium through which the heat units generated at the expense of burning fuel are delivered to the water, and converted into steam, it would seem logical and desirable to have these tubes and heating surfaces render as little opposition to the passage of the heat as possible, i.e., they should be kept clean and free of accumulation. The greater resistance offered to the heat transfer the greater the amount of fuel required to produce the desired results.

The ideal state of affairs is to have both sides of these tubes or heating surfaces perfectly clean. The uneconomical and expensive condition is to have these surfaces coated with unnecessary and undesirable barriers to the heat transfer—the collection of soot and fine ashes on one side, and mud and scale on the other side—the former deposited from the smoke and other products of combustion passing to the stack, the latter deposited from the feed water due to evaporation of the steam.

When it is considered that the dense accumulation of soot or scale constitutes one of the most effective insulating materials known, some idea can be had of the hinderance they present to the passage of heat. The mud and scale on the tubes comes from the feed water entirely, and therefore a remedy against this trouble must be secured by so treating the feed water that the scale forming substances are driven off before being fed to the boiler, as by chemical treatment, or by means of blowing down, skimming devices, etc.,

The loss of efficiency due to the collection of soot is just as important a feature of operation, to which special attention should also be given, and an outline of the causes and remedies will therefore be presented below.

Soot as generally spoken of includes not only the fine particles of unburned carbon, black in color, but also the fine ash, gray, white or black in color which is given off during the process of combustion of the fuel. These fine particles are gradually deposited on the surface of the boiler exposed to the combustion chamber of the boiler, where it lodges and hinders efficient transfer of heat.

Some idea of the non-conductivity of this soot can be had when it is remembered that one-fifth (1/5) of an inch of soot will stop as much heat as a layer of asbestos one inch thick—in other words soot is a more efficient insulating material than asbestos which is so widely used for this very purpose.

Not only does the soot act as a positive handicap to heat transmission, but it also serves to reduce capacity when present in aggravated form because of the effect it has in throttling or choking the draft passages, and cutting down the draft pressure.

The surface of the soot is also such that it absorbs to a greater degree than is ordinarily appreciated the hot gases of combustion, and as a result a layer of stagnant gas is formed about the section of the tube covered with the soot. This stagnant gas film offers a further impediment to efficient heat transmission.

The amount of soot deposit which can be expected will depend on a number of conditions, such as the load carried, whether the fires are greatly forced, whether complete combustion is being obtained, etc. The more complete and efficient the combustion the less will be the soot deposit. The grade of coal burned also has a considerable effect on the soot deposit.

Anthracite coal contains a very small amount of volatile carbon matter and therefore results in the production of but a very small amount of black carbon-like soot formation. The amount of fine ash contained in an anthracite coal, however, results in the presence of a large quantity of very fine flaky light colored ash which clings to the boiler surfaces. This ash-like soot while not offering in itself quite as positive a bar to the heat transmission, is nevertheless quite effective in reducing the heat transfer, especially when it is considered that the presence of the pure black soot will help to bind and hold the ash-like deposit in a semi-solid mass. The ash-like soot also has a tendency to cling to the surface in layers which after alternate baking and re-baking causes a hard accumulation necessitating scraping or hammering in order to loosen and remove it.

Soft, or bituminous coal, is very high in volatile matter, which is given off in great volume during combustion, and hence the soot accumulataion where this kind of coal is used is of a black dense carbon-like form, though with it will be mixed the fine ash and residue which is particularly noticeable with anthracite coal.

Because of its deleterious effect on boiler efficiency, soot formation should in the first place be maintained at the minimum point by careful attention to the methods of firing, draft, air supply, etc., to see that complete combustion is obtained. Then the next step is to see that the soot is removed as promptly as it forms.

Soot can be removed very readily by means of blowing with air or steam, if this is done frequently and before the accumulation becomes too great. If the collection of soot is allowed to become thick, the intense heat present in the furnace will tend to bake and solidify it and in this condition it is difficult to remove, it being necessary to use a scraper of some kind, and in some cases even a hammer and chisel would be necessary to dislodge it.

Obviously the most desirable way is to provide some arrangement for blowing off the soot at regular and frequent intervals before the deposit becomes too thick and heavy to interfere seriously with heat transmission and before it bakes hard. This is advantageous because it will not only eliminate the unnecessary expense of hand cleaning and scraping, with consequent shutting down of the unit, but it also means that the heating surfaces will be kept clean or comparatively clean at all times, and thus a better efficiency obtained.

The soot can be blown off the tubes either by hand or mechanical means, the latter being preferable in every way since it is more reliable, thorough and efficient.

Hand-blowing of the tubes is accomplished by means of a hollow tube or lance through which the steam is directed against the various parts of the heating surface, the lance usually being inserted through the hand-hole or man-hole openings. While hand-blowing, of course, removes the soot at those parts which it reaches, there is always the possibility of overlooking or missing certain parts of the tubes. Hand-blowing at best is a dirty, hot and disagreeable job, and it is therefore to be expected that the operators will endeavor to dodge it as often as possible, and when it is done the chances are that it will be rushed through as quickly as possible to the detriment of the best of results.

The logical thing to do is to install a system of fixed or mechanical blowers so arranged that the steam can be turned on and the tubes blown whenever it is desired with no inconvenience or loss of time. These soot blowing systems convey the steam by means of fixed pipes to various parts of the tubes, where it is distributed by means of movable nozzles, jets, etc. Hence with the mechanical system a better distribution, a more certain distribution, of the steam can be obtained in even the most remote and inaccessible sections, and as a result the cleaning is more thorough. When the mechanical cleaners are installed the hand-hole and manhole openings can also be tightly and permanently sealed so that the possibility of air leaks from that source is also eliminated. The mere fact that the mechanical system can be used without undue annoyance and inconvenience will result in the operators using the cleaner at frequent intervals and hence the maximum efficiency will be maintained. The danger to the men from burns and dust attendant on hand blowing is also eliminated. The cost for steam is also reduced because the mechanical blower can clean thoroughly and in less time a boiler with the expenditure of considerably less steam than the wasteful and more inefficient hand type.

Causes of Failure in Boiler Plates

Effect of Grain Growth—Alteration of Crystalline Structure by Mechanical Deformation—Some Remedies

By WALTER ROSENHAIN and D. HANSEN.

THE occasional cases of failures in boiler plates met with in practice have formed the subject of several papers and discussions before the Iron and Steel Institute in recent years. A number of such cases have been investigated by the authors, and an account of one which offers features of particular importance which do not appear to have been previously noticed was read before the Iron and Steel Institutes in May. These are of special importance because it may be found that they afford a clue to the cause of failure in other cases, particularly in boiler plates of the largest dimensions.

The failure occurred in the last stage of the manufacture of the plate. The size and dimensions of the plate are illustrated in Fig. 1. The plate has a thickness of 1¾ in. and measures 4 ft. 4 in. in width by 11 ft. in length. It was manufactured under a stringent specification, but cracked during the straightening of the edges after the bending operations had been completed. Inquiry showed that the bending operations had been carried out in stages in the cold, the plate being subjected to intermediate annealings between the various stages. The position of the crack which formed in the plate is indicated in the diagram.

The material of the plate was first submitted to chemical analysis, mechanical tests, and general microscopic examination. The results obtained were as follows:

CHEMICAL ANALYSIS

	Per Cent.		Per Cent.
Carbon	0.16	Manganese	0.623
Silicon	0.079	Nickel	0.10
Sulphur	0.030	Chromium	nil
Phosphorous	0.048		

There is nothing abnormal in this composition, which represents a mild steel of high quality.

Tensile tests were taken from the outside and inside of the plate as received, with the results in Table 1, columns 1 and 2:

Here again there is nothing abnormal, except perhaps a slight indication of an unusual condition of the steel in the comparatively large difference between elastic limit and yield stress. It was thought that possibly this peculiarity might arise from the existence of internal stresses in the material, and in order to remove these as far as possible without changing the structural condition of the steel, a portion of the plate was annealed at 550° C. for 30 minutes. The results of tensile tests of a plate in this condition are given in the third column of Table 1. It will be seen that the difference between elastic limit and yield stress is still comparatively large.

In order, further, to test this point, and also to ascertain how far the tensile tests obtained on the material, as received and after annealing at 550° C., correspond to the best properties which the material is capable of attaining, a sample of the plate was normalized by

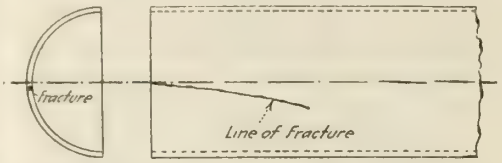

FIG. 1—WHERE THE FRACTURE OCCURRED.

heating to 900° C. followed by cooling in air. The results of tensile tests made on the sample thus treated are given in column 4 of Table 1. Here it will be seen that the elastic limit has come very much closer to the yield stress, while the yield stress itself has been raised. The ultimate stress has only been slightly affected, but, on the other hand the elongation has been markedly improved.

Since the tensile tests showed little or no departure from the normal in the material of this plate it became desirable to apply other tests in order to ascertain whether the properties of the steel were really as satisfactory as the tensile tests would indicate. For this purpose an impact test has been used, for although it is recogized that the conditions under which failure occurs in boiler plate possess no apparent resemblance to those of an impact test, yet experience has repeatedly shown that materials which give a low figure under an impact test are liable to fail under apparently static conditions.

The form of impact test employed is that known as the international notched bar impact test, made with a modification of the Charpy impact testing machine, and on specimens measuring 10 mm. by 10 mm. in section by 53.3 mm. in length, having in the middle a rounded notch with a radius of two-thirds of a millimeter. On the material as received this test gave a mean figure of 0.75 kgm. per sq. cm., the actual values obtained being: 0.84, 0.88, 0.66, 1.08, 0.86, 1.20. These figures are of course very abnormally low, a reasonable value for a boiler plate of this kind being from 8 to 11 kgm. per sq. cm. It was thought that possibly this low value might be

TABLE 1—PHYSICAL TESTS OF THE FAILED PLATE

Particulars.	Plate as Received		Plate Annealed 550° C.	Plate Normalized 900° C.

veur, who made the well-known experiment of straining by compression a conical piece of nearly pure iron, and subsequently annealing the piece thus treated at a temperature below the lowest critical point. On cutting a section and etching it, a band of very large ferrite crystals was found at one point, and this

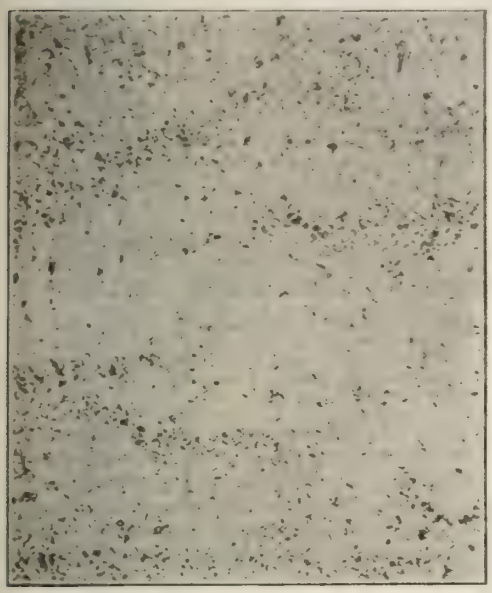

FIG. 10—MICROSTRUCTURE OF PLATE NO. 2 USED EXPERIMENTALLY. VERY LITTLE BANDING PRESENT, THE PLATE BEING ONLY ½-INCH THICK

led to the view that there is a critical amount of plastic deformation which, for a given annealing temperature, below the critical range produces very rapid grain growth.

The subject has been more fully investigated by Chappell,[4] and has also been dealt with in America by Sherry.[5] The latter author has shown that grain growth occurs, not only in comparatively pure iron, but in any region existing in a mass of mild steel from which pearlite is absent or nearly absent—in the carbonless bands such as those met with in boiler plates, provided, of course, that the necessary treatment, consisting of plastic deformation of the right intensity followed by annealing at a correspondingly low temperature, has been applied.

In view of the results obtained by the authors just referred to, the observations made on the boiler plate which forms the subject of this paper at once suggested that the development of coarse ferrite crystals in the carbonless bands of the plate was the result of grain growth following upon deformation in the cold and subsequent low temperature annealing. When it is borne in mind that this plate was bent cold and then annealed several times in succession, it will be seen that the conditions likely to produce grain growth in carbon-free areas had been present.

The authors, however, were not satisfied with a general inference of this kind, but endeavored experimentally to reproduce the conditions under which the steel had developed the coarse and relatively brittle structure which it possessed when received. For this purpose two series of experiments were undertaken. In both series the material was first normalized in order to destroy the previously existing coarse crystals and to bring the material into the condition in which it gives a satisfactorily high impact figure. Deformation was then applied to the material in two ways; in one case, in the cold (by hammering), and in the second case at a temperature between 600° and 700° C., or below the critical range. Specimens treated in both ways were then annealed at 650° C. for 30 min. The microstructure was examined both before and after this last annealing, and impact tests were taken on the material at each stage.

The resulting structure in one of the carbonless areas of the specimen which has been hammered in the cold and subsequently annealed at 650° C. is shown in Fig. 6 under a magnification of 150 diameters. Comparison with Fig. 5 shows at once that considerable grain growth has taken place, although the resulting grains are not quite so large or well developed as those in Fig. 4. The sample which has been hammered between 600° and 700° C. gives a very similar structure, and the impact figure in this case is brought down to 1.56 kgm. per sq. cm.

In order to test the matter further another series of experiments was undertaken in which varying amounts of mechanical deformation were applied in the cold followed by annealing at 650° C. In order, however, to prove that it was not the annealing process alone which resulted in the reduction of the impact figure, the normalized sample was also annealed at 650° C. without previous mechanical deformation. The results obtained by impact tests on specimens thus treated are given in Table 2:

TABLE 2—TESTS ON BOILER PLATE NO. 1

Treatment	Resistance to Impact. Kilogrammeter per Square Centimeter
Normalized at 900 deg. C.	10.46
Normalized at 900 deg. C.	8.92
Normalized; annealed at 650 deg. C.	9.04
Normalized; severely deformed; annealed, 650 deg. C.	11.7
Normalized; reduced 12.4 per cent.; annealed, 650 deg. C.	10.66
Normalized; reduced 7.1 per cent.; annealed, 650 deg. C.	8.44
Normalized; reduced 6.9 per cent.; annealed, 650 deg. C.	10.04
Normalized; reduced 4.9 per cent.; annealed, 650 deg. C.	8.14
Normalized; reduced 3 per cent.; annealed, 650 deg. C.	6.34

In this table the amount of mechanical deformation is measured by percentage reduction of thickness produced by pressing in the cold in a powerful press.

The results given in Table 2 are instructive. It will be seen that large amounts of reduction actually improve the impact strength slightly, but with decreasing amounts of mechanical deformation followed by low temperature annealing the impact strength is very much reduced, although the lowest value obtained in this way, 6.34 kgm. per sq. cm., is still very much better than that

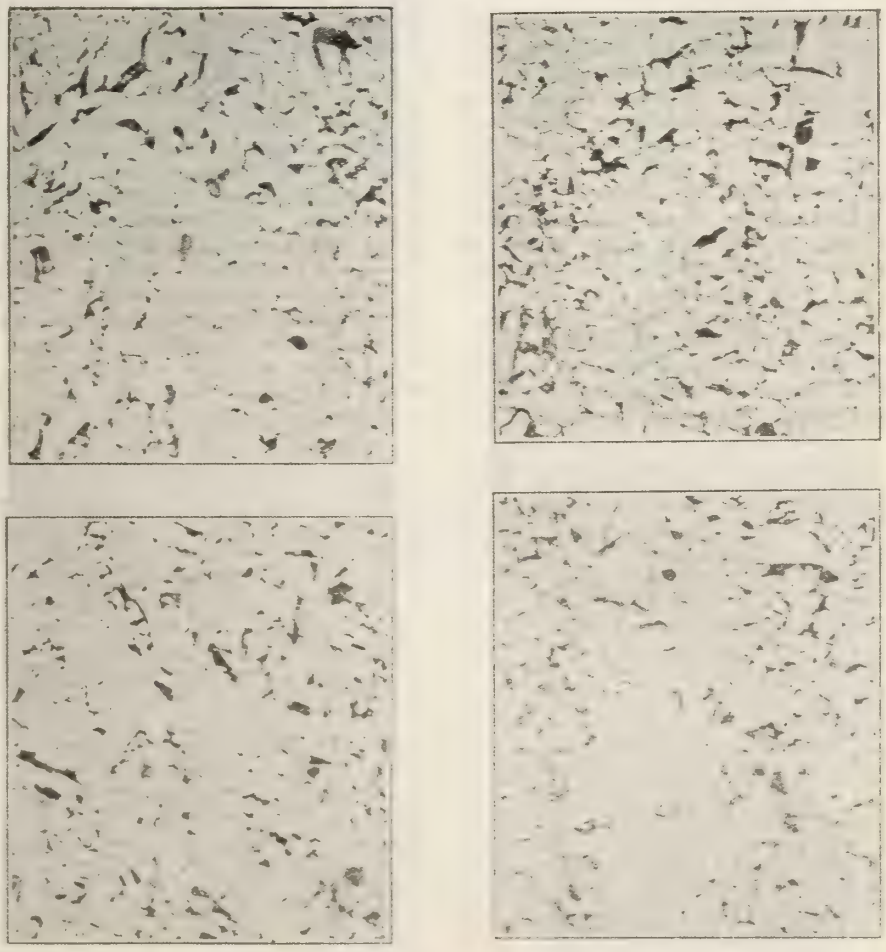

FIG. 11, 12 (UPPER), 13 AND 14 (LOWER), MICROSTRUCTURE OF PLATE NO. 2 AFTER TREATMENT REFERRED TO IN TABLE 2.

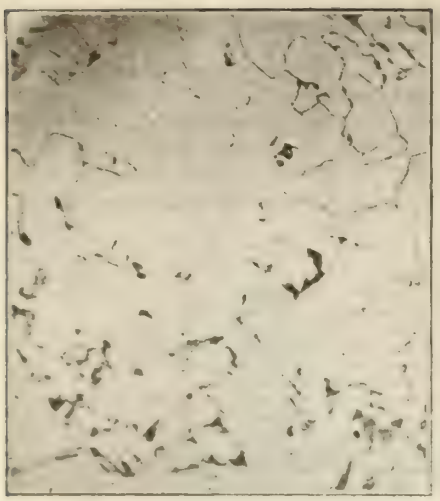

FIG. 4 (LEFT) LARGE FERRITE CRYSTALS IN THE CARBONLESS BENDS OF THE STRUCTURE AFTER FURTHER ETCHING: MAGNIFICATION IS 150 DIAM.

FIG. 5 (CENTRE)—SAME MATERIAL AFTER NORMALIZING; MAG. 150 DIAM.

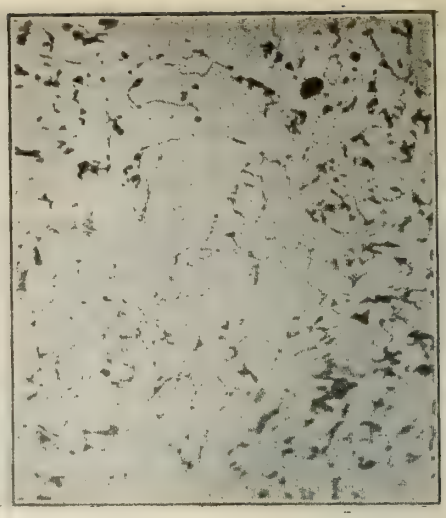

FIG. 6 (RIGHT)—STRUCTURE OF ONE OF CARBONLESS AREAS OF THE SPECIMEN WHICH HAS BEEN HAMMERED IN THE COLD AND THEN ANNEALED AT 650° C. MAG. 150.

due to cold work which the plate had received, leaving it in a work-hardened and, possibly, internally strained condition. The impact tests were therefore repeated on specimens of the plate which had been annealed for thirty minutes at 550° C., in the same way as had been done with the tensile test pieces. The mean result of six impact tests made on the steel in this condition gives a value of 2.90 kgm. per sq. cm., the actual figures obtained being as follows: 2.10, 3.86, 2.64, 3.36, 3.52, 1.92.

It will be seen that this very low temperature annealing, by removing cold work and internal stress has improved the impact behaviour of the material quite appreciably, but that, even when thus treated, it is still very far below the normal value for steel of this grade. This is indicated by the impact figures given on samples of the plate after normalizing at 900° C., when values of 10.78 and 11.72—mean, 11.25 kgm. per sq. cm. were obtained.

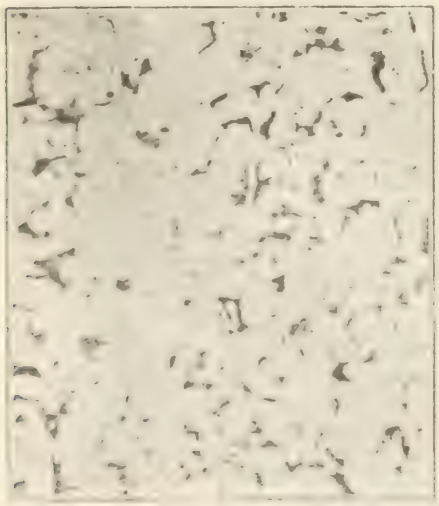
It is evident from these figures that the steel of the fractured plate is in an abnormally bad condition, presumably as the result of some treatment—thermal or mechanical, or both—which it has received during manufacture, and it became necessary to discover, if possible, the cause of this abnormality.

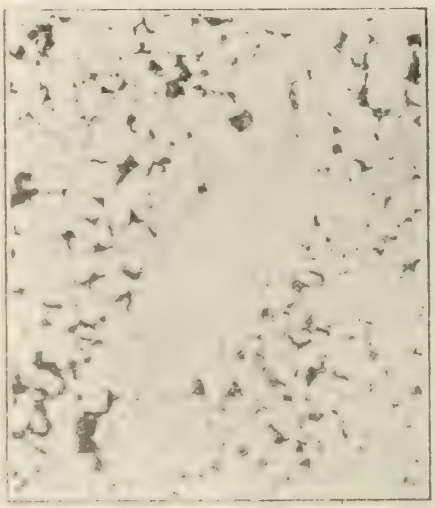
The general microscopic examination of the steel showed at first sight nothing abnormal. The structure in general transverse and longitudinal section is shown under a magnification of 50 diameters in photomicrographs Figs. 2 and 3. It will be seen that the scale of the structure, so far as ferrite-pearlite distribution is concerned, appears to be satisfactory, but there is a considerable amount of banding present, although this amount is not in itself abnormal for a plate of such large size.

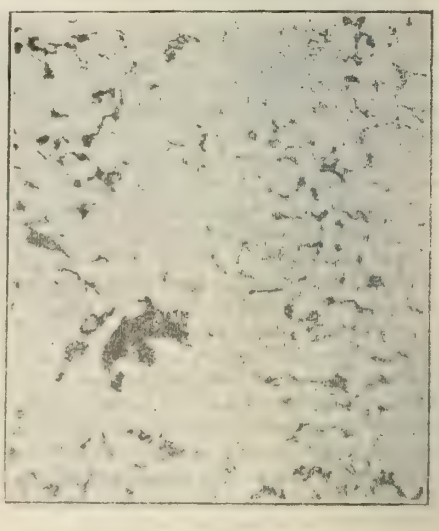
More careful examination of the structure, however, particularly after it had been etched in such a way as to develop the ferrite boundaries, revealed a striking pecularity. This takes the form of relatively very large ferrite crystals in the carbonless bands of the structure. These are illustrated, under a magnification of 150 diameters, in Fig. 4. The corresponding grain size of the same material, after normalizing, is shown in Fig. 5 under the same magnification. It should be noted, however, that the normalized structure shown in Fig. 5 has been obtained not by treating a small laboratory sample but from a comparatively large piece of the plate about a foot square which had been subjected to the heat treatment described. The most careful study of the steel in both conditions revealed no other difference between the "as received" and normalized conditions. The inference is thus indicated that the abnormal impact behaviour of the steel as received may be due to the development of coarse crystals in the carbonless bands which occur in this material, and the possibility is suggested that the failure of this plate may be connected with the phenomenon of grain growth which has in recent years been discovered in the case of iron and very low carbon steel.

The subject of grain growth is of fundamental importance in connection with the further investigation of this plate, and it is referred to it in greater detail at this point.

Phenomena which are now recognized as coming under the general title of grain growth were discovered and described by Stead[1] and Charpy[2]. A considerable advance in our knowledge of the subject was, however, made by Sau-







FIGS. 2, 3 & 5. MICROSTRUCTURES AT 150 DIAMETERS OF THE STEEL, CORRESPONDING TO THE VARIOUS FORMS OF HEAT TREATMENT OUTLINED IN TABLE 3.

found in the plate in its condition as received, or that described in the hammered sample given above. There is nothing to suggest, however, that hammering, as distinct from such deformation as occurs in cold bending, has any specific effect. It should further be borne in mind that when a thick plate is bent in the cold, a considerable range of plastic deformation is produced, ranging from a maximum at the surface of the plate to zero at the neutral axis. Somewhere within this range the critical deformation, corresponding to the annealing temperature employed, is likely to occur.

The microstructure corresponding to the various forms of treatment referred to in Table 2 are illustrated in Figs. 7, 8 and 9, at a magnification of 150 diameters. Fig. 7 refers to the last specimen mentioned in the table having the lowest impact figure and correspondingly showing the largest development of grain growth in the carbonless bands. Fig. 8 refers to the material as normalized and annealed at 650° C. without intermediate deformation. It will be seen that here there is no appreciable difference in grain size between the carbonless band and the adjacent steel. Finally, Fig. 9 refers to the material which has been severely deformed and subsequently annealed at 650° C., giving a high impact figure. Here it will be seen that the grain has been very much refined even in the carbonless areas, and this corresponds in a striking manner with the very high impact figure, 11.7.

When the evidence above described is carefully considered it will be seen to afford a considerable degree of proof of the view that the brittleness, as evidenced by the very low impact figures and actual failure in manufacture which has been found in the plate under discussion, arises from the existence of coarse ferrite crystals due to grain growth in the carbonless bands of the steel, and that this grain-growth is the result of a moderate amount of deformation in the cold, followed by low temperature annealing. It is further evident that normalizing the material, or indeed merely heating it to a temperature above the critical range, is sufficient entirely to obliterate this grain growth and all its evil effects.

It will be seen that this conclusion indicates that the presence of carbonless bands, which is regarded as a normal feature and has not hitherto been considered a serious source of danger or weakness in a boiler plate, may become the cause of failure if associated with a suitable combination of mechanical deformation and low temperature annealing. If carbonless bands are to be regarded as a normal feature in boiler plates—and in existing practice this is probably inevitable—and if deformation in the cold, such as bending, etc., is otherwise a desirable practice, it seems that subsequent normalizing is necessary, or certainly desirable, as a safeguard against dangers of the kind described here.

In order further to test the view which has been advanced above, the authors have endeavored to carry out similar experiments and tests on other samples of boiler plate, but the other samples at their disposal came in every case from plates of much smaller size and thickness, with the result that the banding, where it existed to a marked extent, was on a much smaller scale. Experiments on these plates were, however, made in order that the results might be regarded as a check on the observations already described. In the case of a plate half an inch thick, which may be referred to as No. 2, the chemical analysis was as follows:

	Per Cent.		Per Cent.
Carbon	0.123	Phosphorous	0.057
Silicon	0.014	Manganese	0.49
Sulphur	0.03		

which again indicates a steel of satisfactory composition. The general microstructure of this plate in the condition as received is shown in Fig. 10. A certain amount of banding is present, but not on the scale found in the first plate described. A piece of this plate was

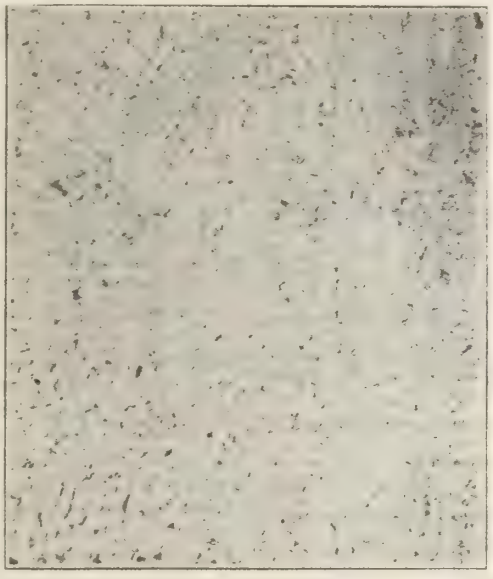


FIG. 15—MICROSTRUCTURE OF ANOTHER ½-INCH PLATE. THERE IS AN ABSENCE OF MARKED BANDING.

normalized at 950° C., and portions were subsequently treated as follows:

Hammered cold and annealed at 650 deg. C.
Hammered between 600 and 700 deg. C., and annealed at 650 deg. C.
Annealed at 650 deg. C. without previous mechanical treatment.

Impact tests have subsequently been carried out on the samples thus treated, with the results given in Table 3:

TABLE 3—TESTS OF BOILER PLATE NO. 2

Treatment	Energy to Fracture. Kilogrammeters
As normalized at 950 deg. C.	11.06
Normalized at 950 deg. C.; hammered cold and annealed at 650 deg. C.	5.52
Normalized, 950 deg. C.; hammered between 600 deg. C. and 700 deg. C., and annealed at 650 deg. C.	7.18
Normalized at 950 deg. C., annealed at 650 deg. C., without mechanical treatment	10.44

It will be seen that the normalized material again gives a high value, and that this value is not appreciably diminished by a further anealing at 650° C. On the other hand, cold hammering followed by annealing at 650° C. lowers the impact figure to one half of the normal value, while hammering between 600 and 700° C. reduces it considerably but to a lesser extent. The corresponding microstructures are illustrated in Figs. 11, 12, 13 and 14. Fig. 11 shows the material as normalized, Fig. 12 shows it after normalizing and reannealed at 650° C. without mechanical treatment, Fig. 13 shows the effects of cold hammering followed by annealing at 650° C., and Fig. 14 shows the effect of hammering between 600° and 700° C., followed by annealing at 650° C.

It will be seen that, in general terms, the results obtained with this material are of the same kind as those found in the first plate but, probably owing to the smaller scale of the banding originally existing in this steel the results are not quite so intense in character. It may be mentioned that this plate also had failed in practice, but not during manufacture, and in a manner which is not necessarily related to the phenomenon of grain growth. The experiments on this plate serve to confirm the observations made with the first example, but they indicate that in plates of a smaller thickness the effects are not likely to be so serious as in the larger plates.

The results obtained with plates Nos. 2 and 3 thus confirm the view that the low impact figures found in the first plate, and to a lesser extent in plate No. 2, are associated with the coarse crystal structure in the carbonless bands, and that these are the result of grain growth produced by slight deformation and subsequent low temperature annealing; also that normalizing in every case completely removes this source of weakness.

New Patents Out.—The following is a list of Canadian patents recently issued through the agency of Messrs. Ridout & Maybee, 59 Yonge street, Toronto, from whom further particulars may be obtained: Samuel R. Kitchen, spring mattresses and the like; Harvey M. Russ, dump wagons; Albert E. Salway, multicylinder internal combustion engine; Joseph H. Price, sights for rifles, pistols and the like; William Wilkie, machines for opening and pressing the seams of wearing apparel in the process of manufacture; John G. Robinson, steam superheater; Robert Blakoe, tires of motor cars and other vehicles; Carl F. Doerschuk, self-locking device; Thomas Mitchell, shim boring and cutting machine; Frank D. Parmenter, attaching means for electric fixtures.

Copper ranks next to steel as the most important war metal. Of a world's production of approximately 3,100,000,000 pounds in 1917, the refineries of the United States produced 2,362,000,000 pounds, or a trifle less than 80 per cent.

TIME FOR REAL ACTION IS HERE

THE time has gone past when it is much use to discuss the saving of fuel in an academic way. The matter has been talked of until it is threadbare, and yet there are plants all over the country which waste fuel every day they operate. The more power they make the more fuel they waste.

The element of compulsion will have to enter into the whole plan before there is going to be much action taken that will be worthy of the name.

It's mighty little use for the government to send out lists of do and don't ideas for the power plants of this country unless they are prepared to go out and follow up these suggestions and see that they are put into operation.

The non-efficiency of the power plants of the Dominion is the cause of the coal waste, and just as long as many of these plants are allowed to run they will run and waste fuel.

There is not enough of the iron fist in the methods adopted by the fuel controller and his assistants. The owners of power plants follow the directions of the fuel controller if they feel so disposed and they refuse to follow these directions or suggestions if such a course meets their fancy. And generally it is the latter case that comes to the top.

If the production of power by a central system is the cheapest and most efficient, then the individual plant should be closed down. If the individual plant is the better way, then the central station should be restricted and disciplined accordingly. There are engineers in Toronto, and reputable ones, too, who are willing to state positively that they can put, by co-operation, anything from 250 to 1,000 h.p. on the power lines during the months when they need a large amount of exhaust steam for heating purposes. The power companies need this power at the same time that the plants need the steam for heating purposes. If this situation is as presented to us, then there should be no option in the matter. It should be made compulsory for that power to be turned into the power line of the large operating companies of this city.

The officials should not be concerned over the fuel that the power plants of the country actually burn, though the tonnage be large. Their chief concern should be over the fuel that passes up the chimney in the shape of gases that have been allowed to escape with only part of their power-producing value taken out, owing to improper combustion.

There is all sorts of advice and assistance to be had for the asking in this matter. In fact the Toronto branch of the C. A. S. E. has expressed its willingness to solve any power house problem that a manufacturer has before him, and these services are offered especially in reference to shortage of fuel at the present moment.

In short, there is one solution that should be aimed at. It might cause some ruffled feelings for a time, but such things are not to be considered seriously now. Insist on a power plant coming up to a reasonable standard of efficiency, or else cut off the supply of fuel until such a standard is arrived at. When the power plant owners find that they are standing up alongside a yard stick instead of measuring themselves with a foot rule, the chances are that there will be some improvement. Until such time we do not look for much progress.

Coal Situation East and West

THE miners in Pictou county, N.S., are out on strike, and have been since early in September. In district 18 of the U.M.W. of A., which takes in Alberta and British Columbia, a strike is likely in a large section of that country, as there is a dispute which has not been settled between the miners and operators.

This, with winter only a few weeks away, and with tremendous demands being made for coal for war industries and other purposes, presents a mighty poor lookout.

The mining of coal in Canada is a poor index of the coal that could be mined in Canada.

Western Canada has a coal wealth that should make her prosperous the year around. The southern part of British Columbia should be busy and developing all the time. It is not. About half the time it is tied up with strikes. On operation and tie-up it looks like a fifty-fifty proposition.

There is a foreign element in Western Canada that is making trouble. That element is feeling its power to-day as it has never had a chance to do before. It is bluffing the whole Dominion, and especially the West. It is playing fast and loose with the big question of supplying Western Canada with coal this year.

Association and Personal

Arthur Crumpton, formerly assistant valuation engineer for the Grand Trunk, has been promoted to the head of this department.

Word was received of the death in Ottawa of Lieut.-Col. W. Mahlon Davis. Lieut.-Col. Davis was for several years the efficient City Engineer of Woodstock, Ont. He was born at Aylmer, and was a graduate of the Royal Military College, Kingston. From there he went to Kitchener, then to Prince Rupert, and later settled in Vancouver. While in Woodstock he was a prominent member of the 22nd Regiment of which he was Adjutant. After going to Kitchener he was appointed Lieut.-Colonel and raised the "Grey Horse" Cavalry, of the Oxford company of which the present Brig.-Gen. John Ross was Major.

When war broke out he recruited a battalion in British Columbia. Later Sir Sam Hughes asked him to raise a pioneer battalion in the east, and in less than six weeks he raised what was known as the 2nd Pioneer Regiment, and went overseas with it some two years ago.

The Hydro Situation.—Speaking at Hamilton recently, Mr. Sifton, engineer to the Hydro Electric department, impressed on his hearers the necessity of conserving the available power. Although by November 1st the Hydro should be receiving 20 per cent. more power than at present, all this extra power will be needed, as the Dominion Foundries and Steel Co. would shortly be putting their electric furnaces into operation, and these alone would consume 2,000 H.P.

Power Is Needed.—At a meeting of the Hamilton Board of Control a letter from the Dominion Forgings and Steel company was read, in which it asked that the Beach road, near its premises, be repaired to facilitate its war business, and that a sewer contractor, at present doing city work under a time penalty, be released for a short time to do important work for it. The company stated that its pay-roll amounts to $250,000 a month, and its work is largely in munitions, and for this reason should be given consideration. The board referred that part of the letter to the works department. The letter also contained this statement: "A few days ago we were refused consideration on a very large contract because power was not available in Hamilton; in other words, Hamilton's industrial growth its stunted because we are at the limit of power." Controller Wright asked about the investigation ordered by the board in regard to Industrial Commissioner Kirkpatrick's charges that the Ontario power committee is discriminating against Hamilton in the matter of allotting power, and the mayor stated that the local Hydro commission was still seeking information to bring before the board.

Epidemic Stops Meetings.—Owing to the growing seriousness of the Spanish influenza in the city of Montreal and the surrounding district, the Board of Health has issued orders for the closing of all schools, theatres and other places of amusements where large numbers of people are accustomed to congregate. These regulations have been extended to include all meetings of societies, clubs and such places where periodical meetings may be held. These conditions will likely continue until the epidemic has been got under control. The current meetings of the Canadian Railway Club and the meeting of the Engineering Institute have been posponed until further notice.

Will Scrap the Road.—The London & Lake Erie Railway & Transportation Company will cease to operate at a very early date and the work of scrapping the road will commence immediately, it was announced by general manager Warburton. There is no likelihood of the city purchasing the whole road and the chance of purchasing even part of it is very small. The idea suggested by Sir Adam Beck some time ago of the municipalities along the line purchasing the part of the road that runs through their district and operating it in connection with the London & Port Stanley Railway was not carried out through lack of co-operation on the part of St. Thomas and other municipalities. A suggestion is now before the city to purchase eight miles of the road that runs between Lambeth and London and connect it with the London Street Railway.

Using Straw for Gas.—Progress has been made in the research conducted by Dr. R. D. MacLaurin, Professor of Chemistry in the University of Saskatchewan, which has as its object the utilization of the waste straw in Western Canada by converting it into gas by the process of carbonization. Dr. MacLaurin has been investigating this project with a view to making the process practicable so that the individual farmer could use his own straw fuel in the form of gas for heating, lighting and power. An experiment was conducted recently by Prof. MacLaurin which proved that it was possible to use the straw gas as motor fuel. A bag containing 300 cubic feet of gas produced from straw was fastened to the top of the car, and this was produced from 50 pounds of straw. This fuel was equivalent to one gallon of gasoline. A ton of straw is capable of producing about 11,000 feet of gas, and is equivalent in power to 35 or 40 gallons of gasoline.

Markham.—The Markham Township Council, at its session in Unionville, gave the Hydro-electric by-law adopted by the Village of Unionville a month ago, its third and final reading, and application will at once be made to the Ontario Hydro Power Commission for the construction of a light and power line from Agincourt. Markham will at once take steps to have the system extended to that point two and a half miles further on.

Chatham.—The city council contemplates drastic action as a result of the alleged failure of the American Well Works Co. to live up to the agreement with the city, when the company purchased the Defiance plant. As an instance, they charge only three men are employed. The city solicitor will be consulted with a view of cancelling all concessions, and instructing assessors to value the property and machinery with a view of compelling the company to pay taxes on the true value.

The Buffalo Forge Co., Buffalo, have issued an attractive catalogue of some 112 pages, pocket size. The pages are made in such a way that they can be replaced—loose leaf style—by others. In its introduction the company says: "In order to simplify the catalogue and also to keep up with improvements which are made from time to time it has been decided to replace the bulky catalogue with sections which are easily and quickly replaced without affecting the rest of the catalogue. Another innovation and one which will be found very convenient, is the renumbering of forges. This numbering is based on the well known Dewey Decimal System of numbering. All forges are numbered according to their blower number. The first figure, therefore, classifies the various forges according to blower, the second figure according to hearth and the third figure according to side of hearth. The letters indicate the style of hood.

The Operators' Point of View

SAVING COAL BY THE ELIMINATION OF AIR LEAKAGE

By W. F. SCHAPHORST.

ON account of the temperature variations in boiler settings it is not always easy to keep it in a leakless condition. Brick settings are perhaps the worst offenders of all in permitting leaks, because they usually crack in time and an enormous volume of air finds its way through to dilute the gases. Some makes of boilers require settings that are prone to cause more serious troubles along this line than others. The greater the surface surrounding the furnace, generally, the greater the danger of loss through air leaks. A low horizontal boiler, therefore, has its own particular advantages, but it must not be forgotten, at the same time, that a large combustion chamber is a prerequisite to thorough and complete combustion.

If there is a leak into the burned gases after they have left the heating surfaces of the boiler no particular harm can result aside from the fact that such leaks will reduce the intensity of draft. It is, therefore, useless to take samples of gases from the chimney itself, especially if there are leaks through the base of the chimney or through the breeching. The proper place from which to draw samples is from the point of departure of the heating surface; in other words, from the place where the heating surface and gases "part company." The samples referred to are those taken for purpose of analysis. For example, if the leaks are of the nature described above the gases would have a smaller CO_2 content in the chimney than at the "leaving point."

Even where boilers are cased in steel or cast iron, air leakage is not uncommon. It is possible for the steel to warp, as every engineer knows. The warp causes a crack or space to form, and "there you are again." A good way in which to detect air leakage is to build a smoky fire and start it a-going nicely. Then, suddenly and completely, close the damper in the breeching and find the fissures through which the puffs of smoke are emitted. Close as many of the fissures or cracks as possible with plastic fire brick or other good material, and then try it again. In a short time a smokeless setting will be the reward. Some engineers have found it profitable to cover the entire setting with a special paint, sheeting, or tarry preparation, for it is claimed, evidently with some truth, that air "seeps" through ordinary brick and its mortar joints.

It is possible to repair the inside as well as the outside of brick settings while in operation if it is found desirable to do so, as it often is. The fallen brick or crack openings may be filled with plastic fire brick applied from the end of the poker or slice bar. The patched job may not look very neat, but it will do temporarily. There are sound arguments in favor of using monolithic structure or lining from this plastic material, thus reducing the leak factor to the minimum. Durability and strength are other advantages of this kind of lining.

One of the prime essentials of efficient firing is the keeping of the furnace doors shut. The fireman should be taught to become skilled in the quick opening of the door, quick though careful discharging of the scoopful of coal, and the quick closing of the door. During every second that the furnace door is open a copious and costly quantity of air is admitted.

GREATER COAL PROFITS

By N. G. NEAR.

Retail coal dealers can do much toward lessening the price of coal if they will just get together and purchase from the mines at a uniform rate and not wait until a certain season of the year as is now so commonly done. They could then make a greater all-the-year-round profit and sell coal at a lower price at the same time. There is no good reasons why mines should not be operated to the same extent during the summer months as during winter months.

The way things are now running mine operators are at a disadvantage. They are not backed by the dealers.

It is therefore evident that if retail dealers will either increase their own storage capacity and buy during summer months as well as during winter months, and advise the consumers to also buy during summer months, the lowest possible average cost per ton will soon be attained.

As for the profits of the retail dealer he must not forget that by building a good up-to-date plant, when increasing size, in order to facilitate handling, he will easily do better than the one who sticks to the old fashioned coal yard.

Power, now-a-days, is cheap. Harness the coal which you are handling to do your mechanical work—all handling. The man with the shovel is decidedly expensive in places where he is not absolutely needed. This has been proved over and over again in hundreds of various fields. There is hardly a detail in the retail business that should be looked after more cautiously than the method of handling.

I would therefore advise retail dealers to investigate the power methods of handling with diligence, if you have not already done so. You will discover many surprises. You will find that hand labor is indeed a luxury.

Thus, by pulling together in two ways —with the mine operator and with power operation—the ultimate consumer will get better service, better coal, and a truly reasonable price. And incidentally you will make more money.

HOW MUCH HEAT IS LOST?

By W. F. SCHAPHORST.

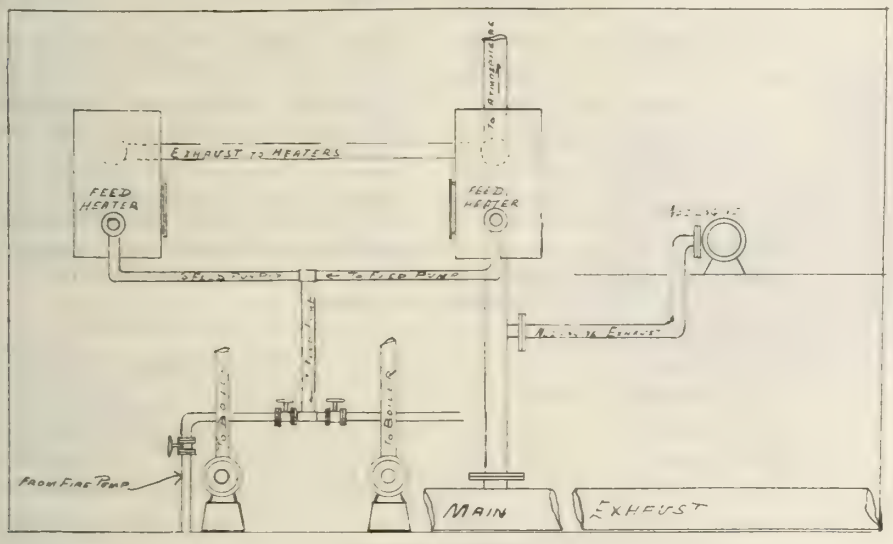
How much heat is lost in allowing a boiler to cool off for cleaning and in starting it up again? There is a question that will cause many an engineer to stumble. It is much like the time-worn conundrum, "Which came first, the egg or the hen?" When a boiler cools off the heat is being dissipated into the air, true enough. And when the boiler and setting are being reheated, the heat out of the coal is all being apparently wasted. None of it is converted into work. The amount of heat lost on cooling is equal to the amount required to heat it all equally again, but the actual loss is "only one of them." Don't add them together. Or, add them and divide by two.

Winnipeg, Man.—The final barrier in the tunnel connecting the east and west sides of the Red River has been broken. The tunnel is to bring the Shoal Lake water to Winnipeg, and all that now remains to be done is to place the cast iron lining and fill the space between pipe and rock with concrete.

A DAY OF REST? IN THE POWER PLANT

By T. H. FENNER

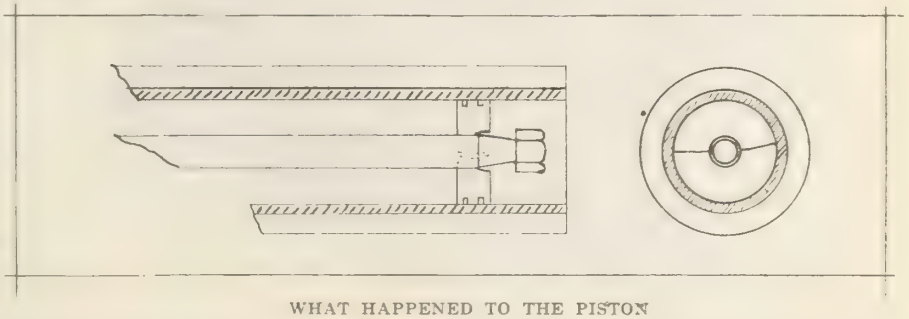
A SERIOUS and expensive breakdown occured to an 11"×9"×14" high speed tandem compound engine under my charge in a peculiar manner. The accident occurred on a Sunday, when the regular engine room attendant was not on duty. As a matter of fact, no one was in the engine room at the time, the fireman on duty in the boiler room being under orders to come up and look at the oiling arrangements from time to time. To understand what happened we must have a glance at the boiler room, where the cause of the accident originated.



PIPING LAYOUT

The feed pumps took their water from overhead open heaters, of the Webster type, discharging through economiser to boilers. There was also a direct discharge to main feed leader direct, by passing the economiser, and also a direct discharge to an auxiliary header, as shown. The suction pipe from heaters to pump came down to a T between the two pumps, and branched off to each pump. There were also two independent suctions on each pump connected to hot and cold wells. On one of these suctions a connection had been made from the discharge of the fire pump for washing out boilers, and an emergency boiler feed. A branch was tapped off the auxiliary header at each boiler to connect the valve of the turbine hose for washing out. When washing out the fire pump was used, discharging through the feed pump suction, through the pump, and auxiliary header. The boiler room staff had stringent orders never to touch this fire pump valve, the engineer on duty in the power house being the only one authorised to make the connection. The reason for this care was apparent, as if the valve from the fire pump was opened and the suction from the open heater left open at the same time, the discharge from the fire pump would have clear access to the heater and from this to the whole exhaust system.

The day that the accident happened being a Sunday, in the ordinary course of events nothing would have been running. However a 50 h.p. armature had burned out on the Saturday morning, and the millwrights and electricians had been working Saturday afternoon and Sunday morning and were ready to try the motor after dinner Sunday. This would mean, if the repairs were O.K., about ten minutes running. Being anxious to know if everything would be alright for Monday morning, I decided to go down to the factory myself. The regular day engineer had been instructed to come in after dinner to run the engine as required, but as he had not shown up I started up myself, made the switchboard connections, and saw that the forced lubrication was alright. I told the fireman where I was going, and warned him to come up at intervals of not more than ten minutes, and look at the engine. I expected to be all through before he came up twice. However, some minor troubles developed in connection with the motor and shafting. A man was sent over to the engine room to see how things were and he reported everything alright. We got ready to start the motor again, and it started up this time perfectly, but after running about five minutes the motor started to slow down and the lights to dim. I started for the engine room on the run, but about half way there was met by the fireman, who informed me in quite a disinterested way that No. 1 engine had "gone to h—." He also volunteered the information that there was a lot of water in the basement. Arriving in the engine room, I saw a tangle of oil pipes, and the broken crank case lying on the floor, and at the same moment an ominous cracking broke on my ears. Coupling this with the fireman's statement of the leak in the basement, I made a rush for the feed pump, finding what I expected, the valve from the fire pump open, and the heaters and exhaust system flooded. The leak in the basement was the excessive overflow from the heaters backing up the water seal from the sewer. The next thing was to look at the water gauge to find the water just bibbing in the bottom nuts of the glasses on the two boilers that were working. I began to reconstruct things a bit in my mind, and then proceeded to catechise that picture of injured innocence, the fireman. The evidence being so complete, he could not deny opening the valves, but hedged a bit about the reason. However, I had a good idea of that, too, and on putting it up to him, he admitted the soft impeachment. He began the course of events by neglecting to watch his gauge glass, and when he did look, found the glass full, but how much more he knew not. However, he promptly stopped the feed pump, neglecting to shut the checks on the boilers. He then resumed his paper, being anxious to see how Foch was making out. Presumably he found the news to his liking, for when he next looked the water was about half glass. He congratulated himself on his excellent judgment in stopping the pump, and thought it would be all right now to start it up again. Here he struck a snag. The boiler checks not being dead tight, when the pump stopped some leakage occurred from boiler to pumps, resulting after a while in the pumps and heaters getting good and hot, too hot to handle water. Deciding that here again was a case for a good man to use his own judgment, he decided to pump some water through from the fire pumps, achieving the double purpose of feeding the boilers and cooling off the lines and pumps. He started up the fire pump, opened the discharge through the feed pumps, and left the main suction open. The water in the boilers did not rise, but it did somewhere



WHAT HAPPENED TO THE PISTON

else, and his ears were soon assailed by numerous strange noises. At the same time his gauge glass lamps started to lose their brilliancy, and it crept into his mind that something was wrong. He went up to the engine room just in time to hear a crash, and had then decided to go and get advice. His view of the matter was that it was decidedly unjust to spoil any poor man's Sunday by involving him in a series of untoward happenings that kept him in a state of nervous tension. Not having time to discuss the matter fully I went to ascertain the damage. I found both the crank pin and crosshead gib straps sheared off, the brasses themselves broken in several pieces, and all the oil piping twisted and broken. The cast iron crank case was also broken, though this was a detail. This was the outer damage. Next thing was to look for the internal troubles. The H. P. cover was removed and an attempt was made to move the piston ahead.. It was apparent at once that something was jammed, and jammed hard, as the hammer rebounded as though from an anvil. It was decided to take the nut off the end of the rod, and a spanner was brought for the purpose, but at the first application the end of the rod and the nut came away together, and it was evident that the rod had been ready to break. We then found that the piston came off the taper surprisingly easy, and after removing the piston from the rod a tentative tap with a hammer was tried on the end of the rod with the same result as before. The next step was to open up the L. P., and this achieved, the trouble was at once evident. The L. P. piston was cracked across, the crack being open from ⅛ in. to 3-16 in., and the piston had been forced over the taper into the parallel part of the rod, jamming on the walls of the cylinder. The only way it could be removed was to drill holes all round the boss and break a piece out, letting the piston come down on the rod, and relieving the pressure. The piston was then taken out in halves. The repairs necessary were new piston rod, new low pressure piston, new connecting rod end brasses, gibs, straps, cotters, and bolts complete, and oil piping, guards, etc., all of which was done at the factory.

Cause of the Trouble

What had happened was as follows: The water from feed pump had backed up through open heaters till they filled up to overflow level. The overflow took care of some of the water, but the level still rose till it came to the exhaust steam opening. Entering this it dropped down to the main heating exhaust and travelled along to the building. Presumably about this time the engineering genius in the boiler room, finding he was getting no water in the boilers, speeded the pump up a bit. There was some back pressure on the engine by now but the water had not yet reached the level of the cylinder. However, shortly after it did, with the results as named. When the final smash occurred the engine was just coming to the back centre. She must have been considerably slowed down from her normal 260 P. P. M., and was probably running about half that. The L. P. piston met a solid wall of water, and the energy of the fly wheel was enough to force the rod through the piston, splitting the piston and jamming everything hard and fast. The fly wheel still possessed considerable energy, the whole of which was applied to move the crank ahead, against the resistance of the immovable L. P. piston. The weakest parts were evidently the straps in crankpin and crosshead, and these parted. The fly wheel evidently made a few revolutions after this, as the connecting rod was thrown back near the front cover, and pieces of the bearing boxes were in the crankpit and on the floor, while the oil piping gave mute testimony of what it had gone through. The shock of the sudden stop on the H. P. end of the rod had to be absorbed by the piston nut, and this had evidently been too much for it. The metal had given, and the piston had loosened in the taper and was ready to let go at the first movement. This shows what can happen through one man's carelessness, and the guilty one should be susceptible to a more drastic punishment than being discharged as in these days being discharged holds no terror for the average fireman.

BURNING LIGNITE WITH THE MECHANICAL STOKER

Considerable difficulty has been experienced at various times in the burning of lignite slack. It is well known that lignite is very friable and although it contains 17 per cent. moisture, burns very quickly and is very difficult to fire by hand if results are to be satisfactory.

Competent engineers in Western Canada have long held the opinion that the most satisfactory way of burning lignite is to feed the lignite slack in a continuous slight stream. For this reason the est recently made at the Government of Alberta power station on the Galt Sprinkler Stoker is of particular interest and shows the excellent results obtained with these stokers in connection with the 200 h.p. B. and W. boiler there installed.

EVAPORATION TEST MADE AT THE GOVERNMENT OF ALBERTA POWER STATION, EDMONTON, WITH LIGNITE SLACK COAL.

Summary of Test.

1.	Date of test	Sept. 19, 1918
2.	Duration of test	7 hours
3.	Type of boiler	Babcock & Wilcox
4.	Heating surface of boiler	2,000 sq. feet
5.	Builder's rating	200 horse power
6.	Method of firing	Galt Sprinkler Stoker
7.	Grate surface	38 sq. feet
8.	Ratio of heating to grate surface	43 to 1

Fuel.

9.	Kind of fuel used on test	Pembina Lignite Slack
10.	Cost of coal per ton at bunker	$2.50
11.	Calorific value of fuel as fired	8,500 B.T.U.
12.	Percentage of moisture	17%
13.	Average thickness of fire	3 inches
14.	Total coal fired (wet)	7350 lbs.
15.	Total coal fired (dry)	6100 "
16.	Coal consumed per hour	1050 "
17.	Coal consumed per sq. ft. of Grate per hour	27.6 "
18.	Ash clinker and refuse	1199 "
19.	Total combustible	5106 "

Average Pressures and Temperatures.

20.	Steam pressure by guage	150 lbs.
21.	Temperature of water fed to boiler	180°
22.	Draft over the fire in inches of water	0.2
23.	Temperature of flue gases	420°
24.	CO^2	9%

Water

25.	Total water evaporated at 180° coal as fired	43,000 lbs.
26.	Water evaporated per hour at 180° coal as fired	6,143 "
27.	Total equivalent evaporation from and at 212°	46,526 "
28.	Hourly equivalent evaporation from and at 212°	6,646 "

Economic Results

29.	Water evaporated per lb. of coal, acutla conditions	5.85 lbs.
30.	Equivalent evaporation per lb. of coal from and at 212°	6.33 "
31.	Water evaporated per lb. of dry coal. Feed water at 180°	7.05 "
32.	Equivalent evaporation per lb. of dry coal and at 212°	7.62 "
33.	Evaporation per lb. of combustible feed water at 180°	8.42 "
34.	Equivalent evaporation per lb. of combustible from and at 212°	9.1 "
35.	Cost to evaporate 1000 lbs. of water into steam from and at 212°	19.8c
36.	Factor of evaporation	1.082¾

Efficiency.

37.	Efficiency of boiler, furnace and grate	72%

100 x item 30 x 970.4
item 11.

Boiler Rating.

38.	Horse power developed per hour	192 h.p.
39.	Percentage of builders rating developed	96%

TEST CONDUCTED BY:
MR. CHARLES A. DEFIEUX,
CHIEF ENGINEER OF GOVERNMENT POWER STATION.

FUNDAMENTALS OF INDUSTRIAL PROGRESS

I have just read Mr. S. R. Parsons' address (under the above heading), at the annual general meeting of the Canadian Manufacturers' Association at Montreal in June last. I beg to be permitted, through the medium of the POWER HOUSE, to express my views on this subject as a timely warning to my brother workmen, especially engineers.

I am certainly in sympathy with all the points in Mr. Parsons' address, especially with reference to the tariff. Personally, I have some experience of free trade and, plainly speaking, I have found it to be the enemy of the working class. Previous to the introduction of free trade in the British Isles there were numerous small concerns, such as grist mills, blacksmith shops, sugar beet factories, and shoemakers, etc., wherein a person could start for himself on very small capital and make a comfortable living.

Those concerns remained in existence for some time after the introduction of free trade, but gradually got swallowed up by the large monopolies.

Free trade created those monopolies which starved out the honest, industrious small manufacturer, because nothing but monopoly could stand against the inrush of imported finished articles. We ought to fight against monopoly and give everybody a chance.

It is also a fact that there were few industries harder hit by free trade than the farmer. He had to stop growing wheat altogether, and there were thousands of bushels of oats imported annually; also hay and cattle, which cut down his profits to a minimum. I am of opinion that if the Western grain growers had five years of reciprocity they would be clamoring for tariff reform.

We are a young country and we have a vast Dominion with abundance of mineral wealth of all kinds. Under the national policy we can develop that wealth and gradually become more and more independent. While under reciprocity our mineral wealth will be allowed to lie dormant and we will gradually become more and more dependent on others. Under reciprocity our hopes of one day becoming a great manufacturing centre are shattered.

Some people are inclined to look at this question only from a selfish point of view, viz., a cheaper cost of living; but they fail to realize that a cheaper cost of living means cheaper labor, or less wages; and if the cost of living was reduced 50 per cent. the farmers' product would also be reduced by that amount. I say, what is the use of a loaf of bread to me if it only costs 5c if I have not the money to buy it?

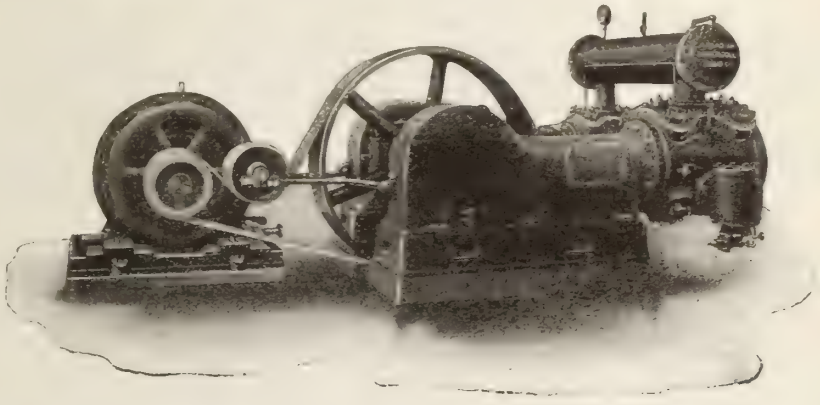
Trusting that my brother engineers will stand shoulder to shoulder with the manufacturers in support of the national policy. Thanking you in anticipation,

R. S. WRIGHT.

THE SHORT BELT DRIVE FOR AIR COMPRESSORS

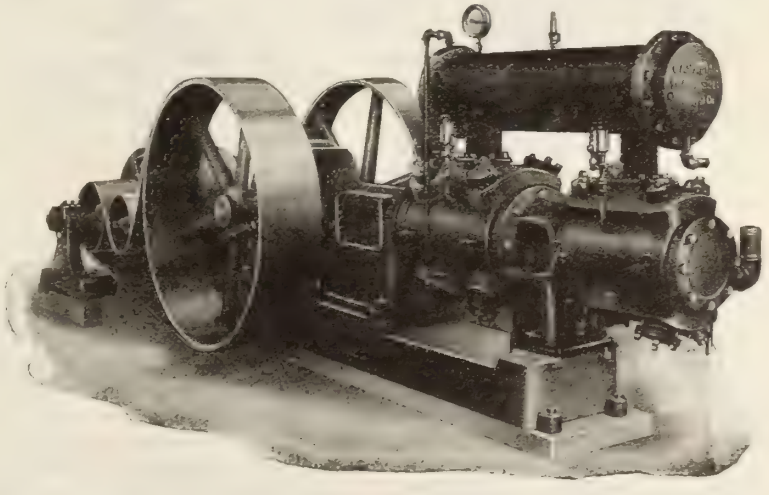
COMPRESSED air is a necessity in most plants. In the machine shop the air chuck is becoming more and more common, air hoists are used for heavy work in the machine shop and the foundry, and in the yard. In the majority of plants that use compressed air the installation of the compressor is usually a problem. In many plants the air compressor has to be squeezed somehow into an existing power-house where space is at a premium, and the question of the compact air compressor becomes very acute.

The steam-driven compressor by the very nature of its construction takes up very little room, but the steam driven type is not so common nowadays, and is usually found where steam is already generated for some other purpose. Now the ordinary belt drive for any type of machine takes up quite a floor space, and the compressor 8 feet long needs almost three times its own length for the ordinary belt drive. For the larger sizes the drive by direct-connected motor solves the space problem, but this form of drive is best suited to compressors large enough to require a motor of 100 H. P. or more, so that the direct driven compressor is not much help to the man who wants to get a small compressor into a corner "two by twice."



The short-belt drive solves the problem for him. The principle of the short-belt drive is best explained by a reference to the illustration; it consists simply of a light idler pulley riding on the belt between the compressor and the motor. But there is an important difference between the idler pulley of the short-belt drive and the ordinary idler; in the short-belt drive the idler is carried on arms mounted on the compressor frame, these arms are free to move up and down to a limited extent. Now the objection which at once leaps to the mind is that this idler pulley will increase friction to such an extent that other benefits will be of little use. However this objection is not so formidable as it looks. If the idler were rigidly fixed the friction would be objectionable, but it is not fixed, and the very slight added friction does not weigh against the advantages of the drive. So much is this the case that at least one large American company makes a specialty of short-belt drive for large mill power transmission of all descriptions.

As to the advantages:—in the first place the short-belt drive saves space; a 10 x 8 inch Canadian Ingersoll-Rand EL-1 air compressor with short-belt drive takes up only 11 ft., 0 in x 3 ft., 0 in.—belt, motor, and all. The outlay on belting is reduced, and the increased contact angle on belt wheel and pulley



adds a good deal more to the efficiency of the drive than is lost in idler friction. Lastly the belt needs no extra initial tension—many a good belt has been stretched too much for its first run;—and the idler automatically looks after tension.

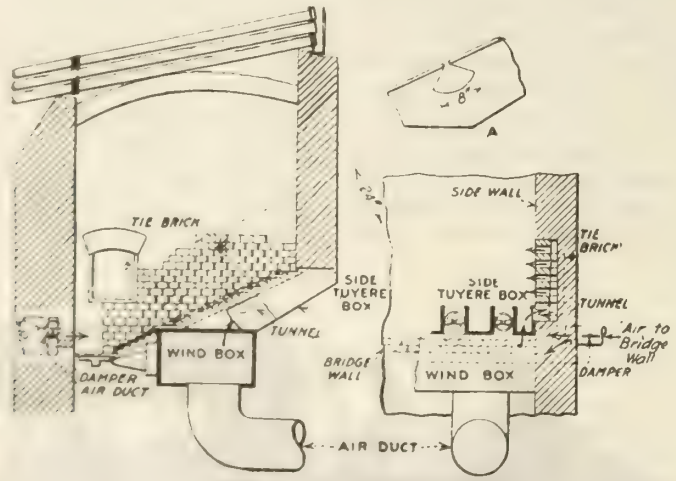
Where compressors are concerned both chain and gear drive are not only very expensive, but they are too rigid, and consequently wear quickly, so that they are not very serious competitors of the short-belt drive—and the short-belt drive is noiseless.

In the installation care should be taken to follow carefully the maker's instructions regarding alignment. The correct location for the idler is just where it would be in the sag of the belt if there were no arm to restrain it. The belt should be slack enough so that it will wrap around the small pulley at least 180 degrees and preferably more usually made up endless by the manufacturer and given a special treatment to make it pliable for this service. With this type of drive it is considered advisable to use belt dressing very sparingly.

THE BERNITZ METHOD OF FURNACE INSTALLATION

Efficiency in power plants at the present time is of the utmost importance and anything making for efficiency in furnace construction, fuel consumption and conservation, constant and uniform service, lessening of labor, and increased economy is specially commendable.

The source of all power derived from coal is the furnace, and a pound of coal saved or more effectively transferred into heat units, results in an increase along the entire line of the power installation Therefore, any improvement in the initial steps in the generation of power is of the greatest value, and it is to this beginning in power plant engineering that Mr. Ernest Bernitz devoted his efforts, resulting in his present invention.



DETAIL OF CONSTRUCTION

The invention has passed through all experimental stages, and exhaustive tests under the most varied and exacting conditions have now fully demonstrated it to be fundamentally sound, mechanically excellent, and commercially successful

Furnaces are constructed largely of firebrick, and whether ordinary grates or automatic stoker grates are used, it is a constant problem to keep the fire burning clear and to secure a maximum of combustion.

The proper combustion of coal is not an altogether simple matter. Coal naturally slags down into clinkers, especially where an intense fire is maintained. Clinkers readily adhere to the sides of the furnace walls, and fuse with the brick and build into masses, preventing a clear combustion of the coal adjacent to such clinkers. The clinker mass extends into and against the grates, obstructing and preventing their being shaken or oscillated, and diminishing the capacity of the fuel bed. The removal of such clinkers presents a task requiring exhausting labor with sledges, hammers, slice bars and the like and is frequently of daily occurrence and one most objectionable to the operators in charge. In order to operate the slice bars and to clear the sides of clinkers it is often necessary to partially or completely dump the fire and subsequent rebuilding in order to work the slice bars and keep the sides clear. The loss of efficiency while fires are down or drawn to remove said wall clinkers, and the even greater loss resulting from the dumping of the fires and rebuilding, cannot be readily determined but is recognized to be large.

The manual labor of running a furnace is another serious phase in the matter of securing boiler room efficiency, the men employed often shirking and half do the job, and frequently leave because of the hard, exhausting tasks. The common and natural result of working the slice bars and hammers is to break off the fire brick so that the entire walls have to be torn down and rebuilt every four or five weeks of use.

Numerous attempts have been made to keep the furnace wall free of clinkers by the use of iron furnace sides and pipes and other devices all of which have proven to be impractical and unsuccessful. This difficulty with clinkers on the furnace walls has been even greater at times in automatic stokers of the under feed type preventing the working and operation of the stokers by choking, etc., and consequently causing uneven and inefficient operation of the entire plant.

The Bernitz method consists in an arrangement of the fire brick in a furnace wall whereby air is admitted into the fuel bed through or between the bricks at the side or at the bridge walls. By supplying forced draft through these air passages, the face brick in the furnace wall is kept sufficiently cooled and consequently free from surface adhesion of clinkers. The consumption of fuel at these points is stimulated and increased.

The formation of clinkers is almost eliminated, the fires are kept uniformly going, and the intense labor, delays and losses incident thereto is reduced to a negligible quantity.

Where forced draft is applied to the furnace fires, a branch conduit to the air passage back of the spaced setting of brick is made, and the same forced draft applied through these narrow brick spaces in the side walls, thus requiring no undue expense. It has been demonstrated that the setting, while largely preventing the formation of clinkers, maintains the fire brick surface in a better resistance condition, so that even when clinkers are formed thereon, they are readily removed by the slice bars without tearing away part of the brick itself, and the furnace wall of fire brick will last indefinitely, from six months to a year, without rebuilding, in comparison with the former conditions at the same plant where entire rebuilding of the furnace wall was required every four or six weeks.

The circulation of air passing directly into the fire from the furnace wall, supplies a mass of fresh oxygen carrying air directly into the furnace fires at a point where it seems to be most needed, where it keeps the fire brick cool and prevents the same from becoming soft or "clinker-adhering." A damper or valve operated from outside instantly controls the amount of air thus supplied. No more forced draft is used than that supplied to the fires under the grates. In installations employing forced draft the desired amount is obtained by simply deflecting a part into the furnace walls provided.

The Bernitz setting as installed by the Bernitz Method Company, Boston, Mass., is usually applied to the side walls and may be applied to the bridge walls with excellent result. A few days watching will quickly determine the proper amount of opening of the damper for the supply of air therethrough.

Safety Code for the Operation of Electric Cranes

Association of Iron and Steel Electrical Engineers Formulates Complete Set of Rules For Operators—Adoption of Rules Will Lead to Fewer Accidents and Less Loss

A COMPLETE set of rules for the safe operation of electric cranes which may be the means of avoiding heavy losses through damage claims and which were prepared after an exhaustive study of the situation with respect to the rights of employers and employees and the law was presented to the Association of Iron and Steel Electrical Engineers by its safety committee at the association's twelfth annual convention in Baltimore, Sept. 11-14.

The committee in its report emphasized the necessity of the employer placing in the hands of his employees printed rules that should be complied with for prevention of accidents, stating that only by so doing may the employer remove the possibility of an injured workman obtaining excessive damages on the grounds that he had not been properly warned. Verbal instruction may be denied and a doubt created which would be favorable to the contestant. The law implies and in some cases demands that hazards of every situation employees are brought in contact with shall be made known to them before they begin work; also that they be instructed how to do their work so that no injury befall themselves or fellow workmen.

The committee declares that the rules should be understood by employers as well as employees and that they should be carried out even at the cost of delays. The rules provide for their own enforcement, each rule being followed by explanatory paragraphs stating the authority and duty of the employee. The rules follow:

1. While the operators of cranes usually are subject to orders of operating foremen, in the departments where they are employed, they should not start a motor even when ordered to do so, if so doing is likely to cause an accident.

(a) A signal to stop the travel of a crane or the movement of any of its parts, by whoever given, should be obeyed.

(b) A motor should not be started, to make a lift, if the operator knows that an improper hitch has been made with chains or slings, or if hooks permanently attached to the crane fixtures are not properly adjusted.

(c) In any case of doubt as to making a lift with safety the crane operator should call the attention of the foreman in charge to the condition that created the doubt.

2. The crane operator should be held responsible for the safe condition of his crane insomuch as he should know by observation from his cab and from inspections of the entire crane.

(a) He should see that all bearings are properly oiled; that all cables are traveling properly on their drums; that brakes, limited devices, controllers, switches, hooks, yokes, blocks and other attachments are in good and proper condition.

3. Operation of cranes while doing construction or repair work should be governed by a code of signals prescribed by the management. They should be given by some one person known by the operator to have authority. On occasions when it obviously is necessary to deviate from this rule the operator should act with exceeding caution.

(a) Cranes engaged in their regular routine work should follow such practices as is the custom in the mills they are operated in and as has been agreed on by the operating management.

(b) Changing rolls, removing and replacing parts of machinery, working two cranes to lift one load, and all unusual operations are classified with repair work and operators should be governed by signals when cranes are so employed.

4. When more than one crane is operating on a runway, an audible signal should be sounded, to avoid collisions when moving. Signals should be sounded when cranes are moving while carrying suspended loads in the vicinity of where men are working.

5. Cranes carrying material should be so manipulated as to avoid carrying suspended loads, or magnets with or without loads, over men working below. In cases where men working below cannot or do not from any cause whatever move away the crane should stop if the line of travel of the load or magnet is over the workmen.

6. Operators on leaving their crane cabs to inspect, oil or repair parts, or to get off the crane, should open the main switch and lock it open with a safety seal lock.

(a) Switches controlling the current to magnets should be kept constantly open and locked open while the magnets are detached, or while they are not in use.

(b) On notification from workmen that they want to disconnect the magnet, the operator should open the main switch and lock it open, before the wires are disconnected.

7. When handling ladles filled with molten metal, the brakes for controlling ladle hoists should be tried to see if they are in good working order before the ladle is moved from over its support. To make this trial the ladle should be lifted a slight distance, then apply the brake to see if it will hold the load.

(a) Ladle cranes with but single motors and outfits for the ladle hoists should not be used to handle a ladle containing metal when the brakes will not hold.

8. Operators should not leave the crane cab for any purpose whatever while a heat of metal is suspended from the crane. In case any adjustment of parts of the crane is required help should be called on to make it.

9. Operators should be responsible for preventing men from riding on their cranes who are not required to do so for some purpose. They also should be responsible for preventing men from riding on any attachment to the cranes as hooks, magnets, etc.

(a) At all times, whether carrying loads or not, hooks and chains should be kept high enough to clear men or apparatus below the crane.

(b) Blocks should not be lowered below a point where less than one and one-half turns of cable will remain on the drum.

10. It is not good practice to make side pulls. If they are permitted they never should be made by use of ladle hoist.

11. Prompt action is required to stop the descent of a load when the brake will not hold. If it should be necessary to apply power to a motor in order to stop the travel of a crane or the descent of a load the contact point of the controller lever should be moved for lifting or reversing as the case may require, one point only beyond the off position. If this does not give enough power then try the second point, continuing the movement one point at a time as necessity requires, but no more power should be applied than is actually required to bring the crane or load to a stop.

12. Two or more safety seal locks for locking switches open should be carried in crane cabs along with the tool equipment. These locks should not be used for any other purpose than to keep a circuit open when the closing of it might cause an accident.

(a) The crane operator should use a safety lock for locking the main switch open every time he leaves the cab to go on the crane runway, or out on the crane for inspection or to make adjustment of parts.

(b) The inspector should, in addition to notifying the crane operator of his intentions, use a safety lock for locking the main switch open, every time he goes out on the crane.

(c) Repairmen should in addition to notifying the crane operator of their intentions, use a safety lock for locking the main switch open every time they go on the crane. The foreman in charge of repairs should be responsible for locking open the main switch and all individual switches, while repairs are going on and for removing the locks when the repairs are finished and the men are off the crane.

How they Cheer for Alexander!

Again he wins in under 40 minutes—

UP stepped Alexander to the start! A rival cleaner was rounding the track at four to six hours to the lap.

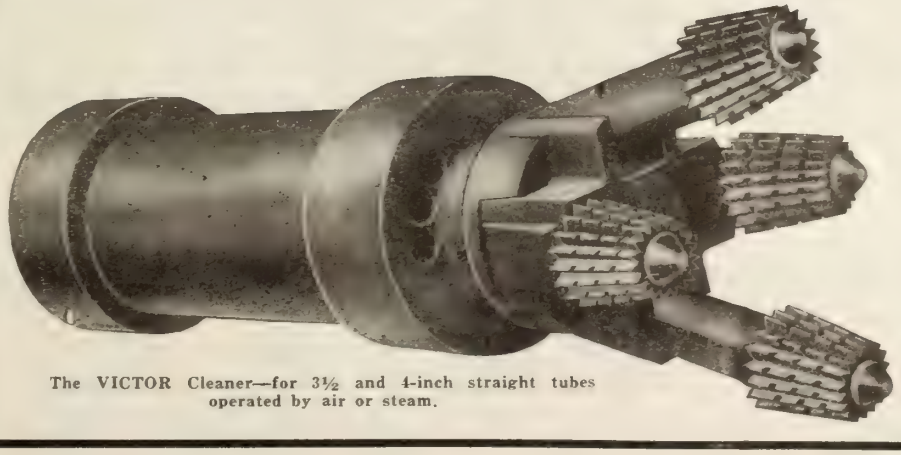
Bang! went the gun. Off shot Alexander, his spurs flashing behind him. Forty minutes was his time on the first tube. Then thirty-four—then a tube in thirty minutes!

Thirty minutes against four to six hours!

Count on Alexander, the Victor Tube Cleaner, for speed and good performance. Ask more about him. Write for Catalog H.

Liberty Manufacturing Company

443 Diamond Street, Pittsburgh, Pennsylvania



The VICTOR Cleaner—for 3½ and 4-inch straight tubes operated by air or steam.

TRADE GOSSIP

London, Ont.—A new heating plant is to be installed in the County Court building, for which tenders will shortly be called.

Summerland, B.C.—The Town Council of Summerland are considering the laying of a pipe line, according to Councillor Johnson.

Rosthern, Sask.—The Town Council of Rosthern have in mind the construction of a plant for sewage disposal, the estimated cost being $15,000. Mr. R. S. Fleury is the mayor.

Preston, Ont.—Tenders for the construction of an 8-inch sewer will be shortly called for by the Board of Works. Mr. Wismer is the deputy reeve.

Toronto.—The Hydro Electric Commission has granted an extension of time on the tenders for the four 52,500 h.p. turbines for the Chippawa-Queenston development. The new date is November 1st.

Change of Name.—The Lauzon Engineering Co., Ltd., of Levis, P.Q., has changed its name to Lauzon Engineering, Ltd. There is no change of directors or staff. Mr. Henry Paquette is the managing director.

London, Ont.—City Engineer Bazur of London is considering alternative schemes for raising the sewage from the low level districts to the level of the city sewers. There are two plans, one being to raise the sewage by direct pumping into the King street sewer, and the other to pipe the sewage over to West London and have it pumped from there when the proposed pumping plant is installed. The objection to the latter plan is the delay that might ensue in handling the sewage from Penman's, Ltd., while waiting to make the connection.

McAvity Plant Growing.—The McAvity machine plant, Marsh road, St. John, N.B., is rapidly developing into one of the largest enterprises of the kind in eastern Canada. The 400-foot unit, which was completed in such record time in 1916, has recently had a unit of similar dimensions added to it and this is being quickly filled up with machinery. But even with this enlargement the firm are not satisfied, for within a few weeks the erection of another large foundry building has been begun on the southern end of the company's lot near Westmorland road. Grant & Horne, who constructed the original unit have the contract for the later additions.

To Save Metal.—Discussing the matter of pig and scrap supplies, a representative of the White Mfg. Co., Guelph, makers of the White Sewing Machine Co., stated that their stock was not being replenished at a very rapid rate. As a matter of fact not more than 25 per cent. of the usual pig iron supply was coming in. The fact that a fairly large stock was kept on hand was helping the plant out now. A change is being introduced by which wooden legs or frames will be used in place of iron, and in this way a considerable quantity of metal will be saved, and the machine frames will lose neither strength nor rigidity.

New Boiler Plant.—The Tidewater Shipbuilders, Ltd., of Three Rivers, Que., are going in for the building of marine engines and boilers at their shipyards. They are installing buildings and plant for this purpose at an estimated cost of half a million dollars.

C.G.E. in Enlarged Quarters.—The sales and supplies departments of the Canadian General Electric Company, Toronto, are moving into their new quarters in the new building which has been erected on the property adjoining the company's head office building at the corner of Simcoe and King streets. The executive, engineering and foundry purchasing department's offices will remain in the main building on the corner.

Start Night School.—The Montreal Technical School is starting a night class for instruction in oxy-acetylene and electric welding, this course will constitute a series of 20 lessons and will be in session every Friday evening during the winter months, commencing on the 4th of October. Mr. C. Royer, manager of the Welding and Supplies, Limited, will be the instructor of the class.

New Boiler Shop.—The Waterous Engine Works are making a $16,000 addition to their boiler house.

Contract Awarded.—The Nova Scotia Construction Company has been awarded the general contract for the Sacred Heart Convent power house and coal cellar to cost $13,000.

The H. W. Johns-Manville Co. have issued a booklet dealing with the waste of fuel in power plants. The pamphlet lists certain common but preventable fuel losses which can be corrected by using proper remedies. Air leakage is dealt with and a method is given of finding leakages. Leaking baffle walls, heat radiation, and heat losses from pipes are dealt with, as well as preventable losses in the engine room.

New Motor Plant.—At a special meeting of the Chatham City Council an agreement was signed between the city and the Denby Motor Trucks Company calling for the erection of a $20,000 plant here, to be ready for occupancy by March 1, next. The plant is to employ at least thirty hands and to pay at least $20,000 a year in wages. The company is newly incorporated in Canada, with a capital stock of $200,000. The city will vote on giving the company three acres of land now, and an additional acreage will be made available if the company needs it within four years.

SOME LARGE TURBINES

The largest turbine in the world is owned by the J. P. Norris Company at Shawinigan, on the St. Maurice River, eighty-four miles from Montreal. The wheel is 30 ft. in diameter, with a horizontal shaft, and is designed to give 10,500 h.p. The runner weighs five tons, and is made of bronze. The shaft weighs ten tons, being 52 ft. 3½ in. long, 22 in. in diameter at the centre, and tapering to 16 in. on the end which is coupled to the generator, and to 10 in. on the other end. The water at the rate of 400,000 gallons per minute flows under 140 ft. head into the casing, which is of the well-known spiral volute form which is seen on centrifugal pumps. The inlet pipe is 10¼ ft. in diameter, and the water enters the wheel all round its circumference, being guided to the wheel vanes in the casing. These guide vanes are pivoted on pins, so that they can be given a small angular movement for regulating the speed. The water, after flowing radially inwards through the wheel, is discharged to right and left through two draft tubes. The direct coupled generator gives alternating current at 2,200 volts 3 phase for transmission to Montreal.

Though the turbines already described are for very high falls of water, it must not be assumed that more modest and less spectacular natural supplies of water power cannot be used. Messrs. Moorhead have a very satisfactory installation for electric lighting and power on the Newry River, the fall being only 5 ft. 6 in. on an old weir formerly used to divert the Newry River to a mill a quarter of a mile away. The turbine was supplied by Escher Weiss, and Co., of Zurich, and is of the radial inward flow type. The wheel consumes 6,200 cubic feet of water per minute, and gives 40 h.p. at 76 per cent. efficiency.

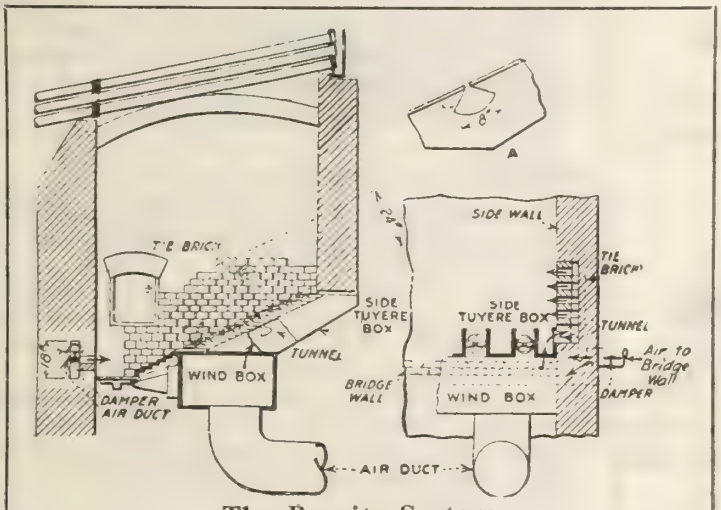
It is suspended from a collar bearing placed above the level to which the water may rise when in flood. The turbine spindle drives a horizontal shaft through level gearing in the ratio of 3 to 1. An overhead shaft is driven at 300 revolutions per minute by belting from the first shaft, and itself drives through belting a compound-wound four-pole direct current generator at 650 revolutions per minute. The dynamo gives 130 amperes at 230 volts. The loss in the transmission is only 7.2 per cent. over all, and the installation proves that in this country, where low heads only are available, the natural reserve of energy available in our rivers may be usefully and efficiently tapped.

At the present time the most remarkable development of water power is taking place in Sweden, where it is estimated that 4,000,000 to 6,000,000 h.p. is available, the power is for tramways and lighting for a hydro-electric railway, and for carbide, steel, zinc, and nitrate factories. Of 100 towns in Sweden, sixty-nine have hydraulically generated electric power stations finished or in course of construction. Three hydro-electric installations have been built for the State of Trollhatten, Elfkarleby and the Porjus of 60,000 h.p., 45,000 h.p., and 50,000 h.p respectively.

Add Power to Your Furnace

by eliminating the fuel-waste resulting from the "freezing" of clinkers to the side walls. The Bernitz Method of constructing side walls with interior air passages through which cooling air currents are passed to keep the bricks below the fusing point will

Positively Prevent the Accumulation of Clinker Mass



The Bernitz System
as applied to a Taylor Stoker Installation

The Bernitz Method

1. Saves coal by insuring more perfect combustion of the fuel used.
2. Increases boiler efficiency by shortening time spent in cleaning walls.
3. Increases efficiency by burning coal which formerly clinkered.
4. By shortening time spent in cleaning walls reduces influx of air through doors.
5. Saves B.t.u.'s usually lost by radiation through side walls.
6. Permits increased forcing of fires by eliminating danger of clinker "freezing."
7. Makes it possible to remove such clinkers as are formed without dumping fire.
8. By reducing manual labor in boiler room keeps laborers more contented.
9. By keeping fires clean insures greater uniformity in heat applied.
10. Is equally applicable to old or new constructions.

The Bernitz Method is licensed, not sold. It has received full patent protection in Canada and the United States and in foreign countries, and licenses under these patents are being granted on the basis of the H.P. rating of the boilers under which the Method is to be installed.

FOR SALE

FOR SALE CHEAP—ONE 30 K.W. GENERATOR Set 220 Volt D.C. Ideal Engine—Westinghouse Generator on sub-base—Switchboard; one 20 K.W. Generator Set on sub-base, same as above. These two sets are in perfect condition and we offer decided bargain for quick sale. Winnipeg Machinery Exchange, Sutherland and Gladstone Sts., Winnipeg.

FOR SALE—ONE 42-INCH, DOUBLE PLY, Viking brand, waterproof, leather belt, seventy-five feet long, in perfect condition, being operated only four thousand hours under normal load. Apply Public Utilities Commission, London, Ont. p10h

POSITION WANTED

STATIONARY ENGINEER WANTS A POSITION. Can handle all makes of engines or boilers. First-class man. Holder of certificate. Apply to Chas. Mismer, 920 Concession Street, Mt. Hamilton. (p11h)

WANTED.

REFRIGERATING ENGINEER REQUIRED TO take charge of plant in Montreal. Apply stating experience. Box 621, Power House. (p10h)

WANTED—STEAM OPERATING ENGINEER, to act as erector for steam specialty. Should be good steamfitter. Excellent opportunity. Write, stating age, experience, salary expected to start and give references. Address Box 619, Power House. p10h

BOOK REVIEWS

The Austin Book of Buildings (No. 5), just off the press, is a 64-page volume completely covering the length and breadth of the service as performed today by the Austin Company, Cleveland.

A perusal of the index shows the following well defined departments of this new catalogue. Starting with a definition of "The Austin Methods," its chapters cover the ten Austin Standards Building Units, Railway Standard Units, ters cover the ten Austin Standards, Specifications, the Austin Industrial Building Service, its equipment service, and export service. It also includes a long list of owners of Austin-built buildings, and a full explanation of the way to use Austin service to save time.

More than a half a hundred illustrations of interiors and exteriors, made from photographs are to be found on its 64 pages. Some are illustrations of the Austin Standards without special architectural features, others show how it is possible to adapt a standard proposition like the Austin Company's to special requirements. Different architectural details are shown to be easily met, whether for one building as in the case of the Dayton (Ohio) Metal Product Company or a large group of buildings as in the case of beautiful Nela Park (The National Mazda Lamp Works at Cleveland) where the architect's specifications were fully and satisfactorily met.

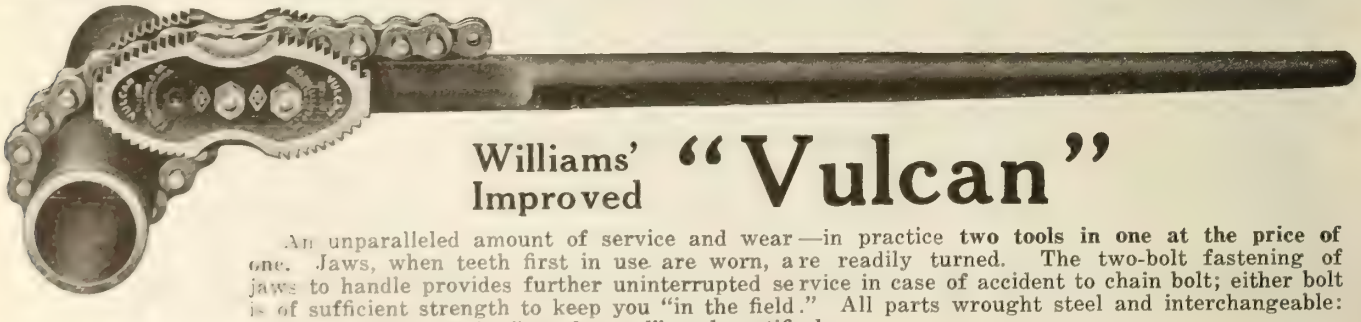
The Nela Park group is worthy of particular mention, for it includes an engineering building, sales building, administration building, research laboratory, working building, power house, garage, purchasing and service buildings.

Detailed drawings of all cross-sections, floor plans, side elevations, front elevations, etc., are given. Also full specifications for each standard, the exact uses for each type of building, as well as their adaptability to crane service of attractive Austin interiors and exteriors.

"Condensers, Pumps, Cooling Towers, Etc.," is the name of Bulletin 112-A just published by the Wheeler Condenser & Engineering Co., Carteret, New Jersey.

Readers contemplating the installation of a condenser will be interested in a discussion in this bulletin entitled "Choice of Kind of Condenser" and in the remainder of the bulletin which illustrates and describes other Wheeler condensing machinery in detail. The bulletin embraces large and small surface condensers showing typical complete installations, rectangular and cylindrical types, jet condensers, barometric condensers, Wheeler Edwards air pumps, Wheeler rotative dry vacuum pumps, the Wheeler turbo air pump; centrifugal pumps for circulating water, neutral and forced draft cooling towers. In addition a page is devoted to the Wheeler feed water heater and two pages to Wheeler multiple effect evaporators and dryers.

Peterborough.—The Town Council of Lakefield are looking for quotations on 6, 8 and 12-inch water mains. They are also considering the purchase of a double cylinder chemical fire engine.



Williams' Improved **"Vulcan"**

An unparalleled amount of service and wear—in practice **two tools in one at the price of one.** Jaws, when teeth first in use are worn, are readily turned. The two-bolt fastening of jaws to handle provides further uninterrupted service in case of accident to chain bolt; either bolt is of sufficient strength to keep you "in the field." All parts wrought steel and interchangeable: **each and every chain "proof-tested" and certified.**

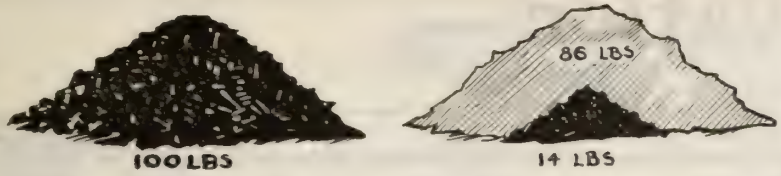
Study The Piles



Seven Times the Power for the Same Coal

The first pile represents coal used making steam to feed boiler using direct steam pump.

The black part of the second pile shows the relative amount of coal necessary to do the work with a Cole Return Trap.

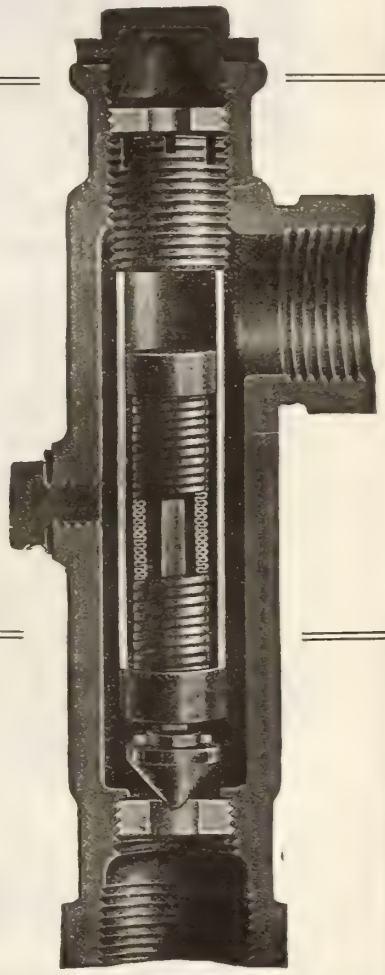
In other words, you get seven times the power for the same coal—or 86% of the fuel saved.

If you want further proof get our latest folder on boiler feeding—No. 9.

GEO. W. COLE, Ltd. 2002 Dundas St. W. TORONTO

STEAM TRAP SARCO

Is Hydraulically Operated
Automatic—Positive—Sure



The employment of the hydraulic principle as used in the Steam Trap Sarco gives this trap unique advantages and insures absolutely positive action.

Saving of fuel is an "essential industry" and the saving of steam means a saving of fuel.

The Sarco is small, compact, 100 per cent. automatic and small in cost. It can be used as an elbow or bend in any steam line. Its small cost makes it practical and profitable to trap steam lines at many advantageous locations (instead of one point).

When you plan to use a big, heavy, expensive trap, you cannot trap where you ought to, but where the trap fits. The Sarco fits everywhere and you can buy six for the price of a bucket or float trap. It is supplied for any pressure from 0 to 200 lbs.

Free 30-day trial will conclusively prove the value and need of the Sarco. Write for Circular No. J-6.

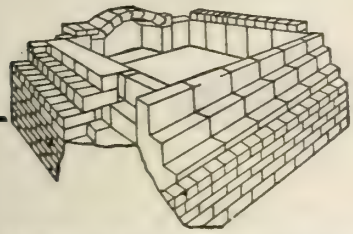
NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.



Gates Boiler Furnace
Patented 1916

Will last three times as long as ordinary good grade Fire Brick. These blocks are inter-locking, and made so that any handy man or fireman can renew them without disturbing any of the other brick work.

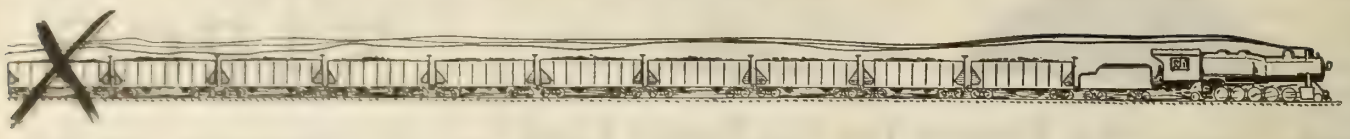
Real Conservation—



GREEN'S ECONOMISERS

save one or more cars out of ten.

THE use of Economisers is more important now than ever before and all new plants should be equipped with them, also all old plants that are engaged in essential work.

The others will have to wait until after the war.

Some of the reasons for the importance of Economisers now are:

FIRST—They save 10 to 15 per cent. of the coal that would be needed if the boilers were operated without them.

SECOND—They can be used to increase the present boiler capacity or to get greater capacity out of new boiler equipment.

THIRD—The coal saving releases cars and railroad facilities which are very important under present conditions.

FOURTH—This saving also helps in overcoming the shortage of miners caused by enlistment or drafting.

FIFTH—If used to increase the boiler capacity this releases boilermakers and steel that can be used to make boilers for marine service and other important uses.

The complete list of reasons is too long to be given in detail. Our Engineers will be glad to give you others and also explain the application of Economisers to your plant.

A new Economiser Catalog will be ready soon. May we put your name on our mailing list now? Just fill in and send the coupon.

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction*. Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs*. Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

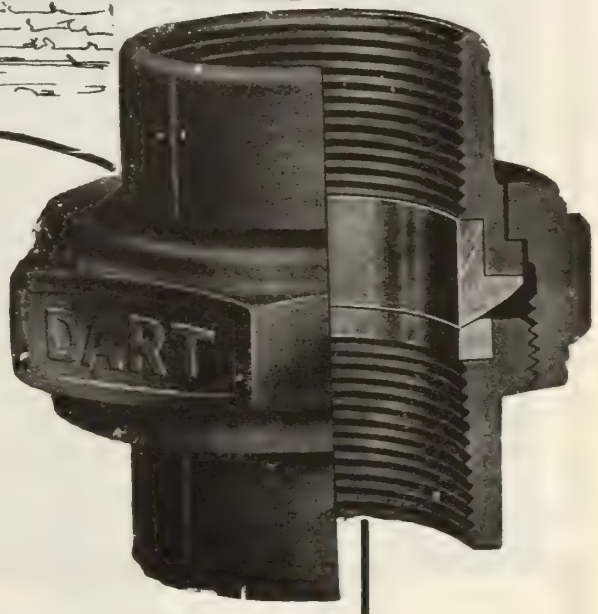
Permanence



Dart Unions

are as the Pyramids in the Pipe Coupling World

Bronze to Bronze at the joint

They stay perfectly tight for years and years.

Require no attention when in service—never have to be replaced—and they can be disconnected and connected as often as desired without affecting their efficiency.

THE SECRET OF THE DART'S PERMANENCE lies in the facts (1st) that both faces of the joint are BRONZE (a non-deteriorating metal); (2nd) that the HEAVY IRON PARTS will not stretch or pull apart; and (3rd) that they are made in a factory whose only product is Dart Unions.

Pipe coupling trouble and their upkeep expense do not exist where Dart Unions are used.

DART Unions Never Leak

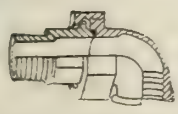
The Union for Power Plant Service—JEFFERSON

Whether hidden in a dark corner, hundreds of feet below the surface, or located within easy reach, you can depend upon JEFFERSON UNIONS to give perfect service wherever they are put to work. Rid yourself of power losses, leaks and pipe line troubles of all kinds by using JEFFERSONS.

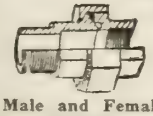
Why take chances with "Just-as-good" unions? The efficiency of the entire pipe line depends upon the quality of the unions installed. By selecting JEFFERSON UNIONS you are assured of perfect service under the severest test that can arise.

The Patented Brass Seat Ring, the Ground Ball Joint, the extra weight and high grade, air-refined malleable iron, etc., are all features to the success of JEFFERSON UNIONS.

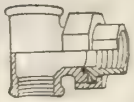
Your jobber has JEFFERSONS in stock. Get his opinion of them and you'll have no doubts as to the right union for your job. Write for our catalog, "UNIONS," which shows all types and sizes.



Union Elbow, an economizer of the most pronounced type. Also made all female.



Male and Female Union. Takes the place of an all-female union and a nipple. Makes a short connection.



Union Tee, with union on the outlet. Made also with male end on outlet.

Reducing and Regulating Valves

Before you install your valve, be absolutely sure on these three points.

1. **The right kind** of valve is the one that is adapted to your particular service. No one type will answer all purposes. Different service and at times different conditions in the same kind of service necessitates different types of valves.

2. **The right size** of valve is the size that will make the proper reduction and regulation and has a wide enough seat opening to prevent obstruction and cutting out of the seat. *A general fault is using a valve that is too large.* Ordinarily they should be smaller than the pipe to which they are attached.

3. **Proper assembling** means that valves should have working parts suitable to service, and diaphragms and springs suitable to pressure range.

Don't guess. Consult us. When valves are installed under MUELLER supervision, we fully warrant them to perform the service for which we recommend them.

We make valves for water, steam, gas, air, oil and ammonia. There is a stock valve in our catalog that will meet your needs. If you have a specially intricate problem to solve, our experts are at your command.

METLSKIN does prevent scale

Send for this illustrated booklet. It explains the dose, the method of action, and other important details

Some of Canada's and the United States' biggest and most representative plants have learned the truth of the above statement from first-hand experience.

So many "compounds" and "cure-alls" have been foisted upon unwary power-plant owners that the feeling, common to many of them, is one of doubt, of skepticism. And small wonder!

METLSKIN is not a "compound," nor does it work on the same principle. It is a boiler metal treatment, a boiler preservative that gradually removes scale by a safe process.

When the scale has been entirely removed METLSKIN forms a minute, grayish-white skin or covering over the bare metal.

So long as the daily dose is continued the scale-forming particles in the feed-water cannot adhere to the metal. Nor will METLSKIN work injury to any part of the boiler or system. That is one of the strongest features of the GUARANTEE BOND.

METLSKIN cannot contaminate the steam. It may be used safely in any plant where live steam comes in contact with the manufactured product.

If you are a skeptic, a doubter, ask for the booklet, GUARANTEE BOND, prices, etc. You will be interested, we know.

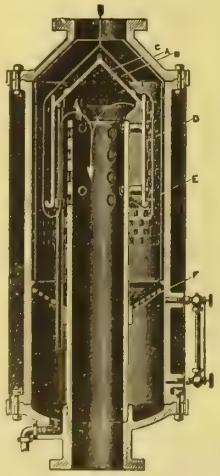
III IMPORTANT THINGS

TO CONSIDER ABOUT A SEPARATOR.



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

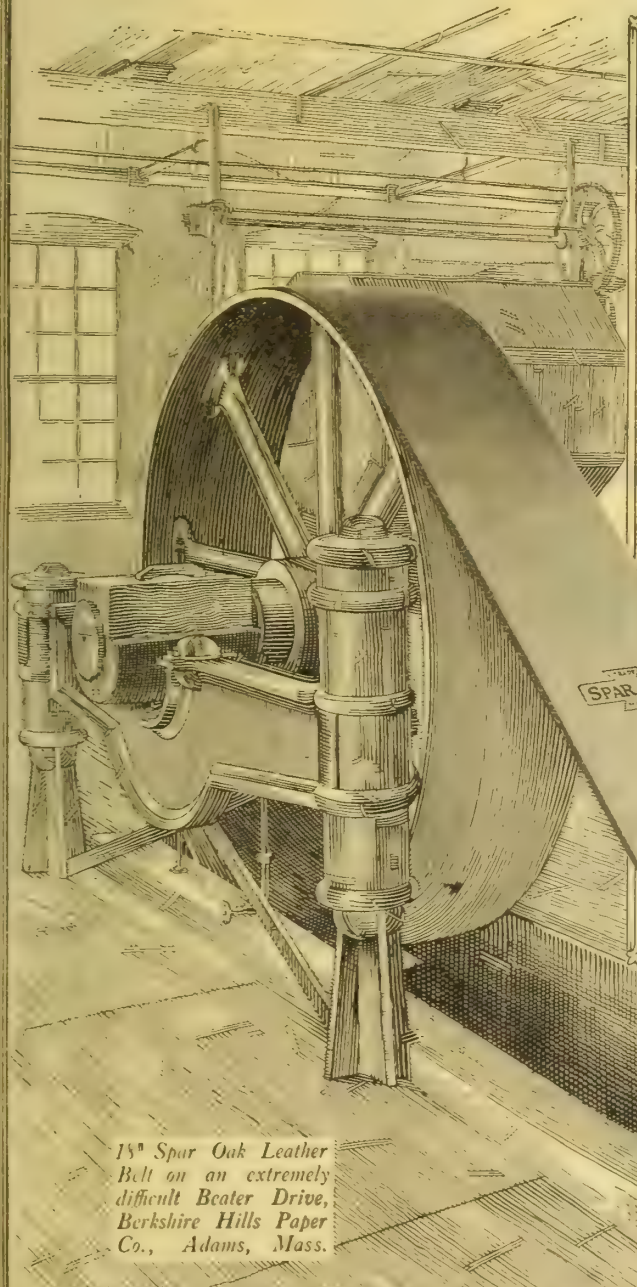
Standardized Series

LEATHER BELTING

Tanned by us for belting use



15" Spar Oak Leather Belt on an extremely difficult Beater Drive, Berkshire Hills Paper Co., Adams, Mass.

BRUISING DRIVES

Constant trouble-maker drives become highly efficient when equipped with SparOak—that double service belt.

The pulley surface of SparOak Belting is Graton & Knight Spartan Leather—the highest frictional value ever attained in belting. The outside is finest quality of heavy Oak-tanned center stock. The combination gives a belt that not only grips the pulley at high speed with fluctuating loads, but stands the mauling of hard service conditions.

If you have a troublesome, bruising drive, don't delay in learning about SparOak. For a whole class of belting dilemmas it is the answer.

Send for our new book—"Standardized Leather Belting," which describes the character and application of SparOak and others of our Standardized Series.

CANADA'S DEPARTMENTAL HOUSE FOR MECHANICAL GOODS

We like the way General Manager B——— mentioned the

Alberger MULTI-HEAD Heater

He had acknowledged the absence of all trouble common to most water heaters. Not a tube had clogged (the corrugations prevent clogging). Not a tube had buckled or split. (On the one hand the "floating" heads eliminate the danger from contraction or expansion strains; on the other hand, Alberger pure copper tubes, unlike brass tubes, do not split when subjected to temperature changes.) "And as your heater provides hot water as fast as it can be drawn, it is quite satisfactory," he told us.

The Alberger Heater transmits 50% more heat than plain tube heaters of corresponding size. **Bulletin 201 explains fully.**

TOOL COMPANY.

COLBURN MACHINE TOOL CO.

About a year ago, when we decided to build an addition to our plant, the matter of furnishing power became a serious problem on account of the fact that our power plant was already overloaded and we did not at that time want to install any more power units.

After compiling considerable data we decided to equip our new addition with S.K.F. ball bearing line and countershaft hangers. The self aligning feature of S.K.F. bearings appealed to us as being superior to other makes. We were greatly pleased with the results obtained from this installation, and immediately put in hangers on one of our old line shafts; also countershafts for large grinders and automatic screw machines, with the result that after adding considerable new, heavy machinery, we are experiencing no more trouble with our power plant, having ample capacity to run our shop 21-3/4 hours per day.

The actual saving on a large Landis grinder countershaft is 50%, others running from 20 to 40%, and line shaft from 15 to 25%. These savings were all proven by actual motor tests.

We estimate that the saving in cost of maintenance and shut downs due to hot and worn out bearings alone, will pay for the installations in a few years time. Had we not adapted this method of saving power, it would have meant the purchase of an entire new power unit, costing several thousand dollars.

We are replacing all line and countershafts with S.K.F. hangers throughout our plant as rapidly as we can arrange to put them in.

Yours very truly,

COLBURN MACHINE TOOL CO.

W. M. Breckenridge
Treasurer.

The Story of War Under the Earth

THE German sappers had discovered and broken into a Canadian tunnel. They had planted a machine gun at their end and sent a shower of bullets down the dark, narrow passage whenever the Canadians made any effort to enter their underground galleries. The story of how two Canadians nailed steel snipers' shields to the front of a push cart and shoved it ahead of them up to the very teeth of the gun, and how they dropped a can of deadly explosive, hopped on to the cart, and let it coast back down the tunnel, while bullets rattled on the shield like hail and, finally, how the explosive blew up the machine gun and its crew and blocked the passage again—this remarkable story is told by Lieut. C. W. Tilbrook (who was one of the two) in the course of an article, "An Underground Tank," in October MACLEAN'S.

Recently a Toronto newspaper declared editorially that the public was tiring of war books and war stories because of the sameness of them. The newspaper was right. But the public literally devours any story of the war that is new. The series of articles that Lieut. Tilbrook has done for MACLEAN'S have been read with an astonishing amount of interest *because they are different from anything that the public has yet read.*

Warfare in the tunnels is a terrible business—grim, silent, cruel. It is a strangely technical phase of warfare and the "sappers" go about their business with queer instruments that might have figured in a Jules Verne phantasy. To read of underground fighting, as Lieut. Tilbrook tells of it, is to get a vision of a new kind of war altogether—something gripping, fearsome and mystifying.

"An Underground Tank," is the best of his series. But, after all, it is only one feature in a long array that makes the October issue of MACLEAN'S one of unparalleled interest.

A STRANGE CHANGE IN WOMAN'S WORLD. By Agnes C. Laut.
The new status of women, arising out of the war, is treated in the powerful style of this famous writer, who came from the Canadian West. It introduces a new thought.

CONSCRIPTION AFTER THE WAR. By Brigadier-General A. C. Critchley.
A young Canadian who rose from Lieutenant to General in three years and originated the "Critchley Method" of military training, tells what he thinks about the need for compulsory service after the war.

THE LIFE OF MARY PICKFORD. By Arthur Stringer.
The second of a series of articles on Canada's most famous woman. No expense has been spared to produce the beautiful illustrations specially posed for the photographs.

THE FOUR FACTIONS AT OTTAWA. By J. K. Munro.
That the House will split into four, more or less, distinct groups is the guess of the author, a trained political observer. He outlines the reasons humorously, pungently and impartially. It is a political article on new lines and will be found refreshing.

BONEHEAD BILL—Another Service Poem.
Robert W. Service, most popular of poets, sends all his war verse to MACLEAN'S. In "Bonehead Bill" he depicts the grief of a soldier for his fallen foe.

THE EVENTS OF A MAD WORLD.
are summed up in the "Review of Reviews" which gives reprints of the best articles from the magazines of the world. All the best and most important articles are selected—five dollars' worth for twenty cents!

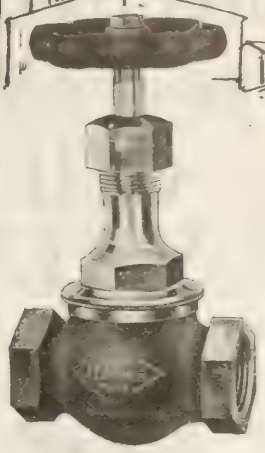
Jenkins Bros. Valves



EVEN an apparently insignificant hiss of steam past a poorly seating valve will cause a material fuel loss per year. Multiply this figure by the number of valves in the average plant and the loss becomes appalling.

Dependable valve service is essential—more so now than ever before in view of the great scarcity of fuel.

No matter what the type of building or plant, the best valve service is necessary. Installing good valves at the start saves repair and replacement charges and the labor costs of re-installations later.

Whether you require valves for industrial plants, public or private buildings, **Jenkins Bros.' Valves** should be your choice. You can rely upon them under conditions where other valves would fail.

They will hold absolutely tight under steam, water, air and gas pressure for very long periods of service without attention. The design is heavier than the usual commercial standard pattern of other makes, enabling us to guarantee them for 175-lb. steam or 250-lb. water-working pressure. All are fitted with renewable Jenkins discs made of a softer composition than the metal and which will seat perfectly tight in spite of inequalities or rough spots in the metal surfaces. When worn the discs may be replaced at trifling cost and the valves will become as tight as when new. The composition of the discs is varied to suit the particular requirements of each class of service.

Furnished in brass or iron body, in globe, angle, cross, check, Y or blow-off, hose whistle and other patterns.

The MacLean Business & Class Publications in Canada

TO SELL or buy from Canada such lines as machinery, hardware, food products, dry goods, books and stationery, paper, printing machinery and supplies and general merchandise of almost every description, raw or manufactured, use or consult the MacLean Business and Class Publications, as per list below. For special information, write the publishers. Concerning the quality of the MacLean publications, let this copy of POWER HOUSE which you hold in your hands speak for all. The MacLean list of 14 publications is as follows:—

The Canadian Grocer (Est. 1886)
Serving the Grocery, Provision and Foodstuffs Trades. Published weekly.

Hardware nad Metal (Est. 1889)
Serving the Hardware, Stove and Metal-working Trades. Published weekly.

Dry Goods Review (Est. 1889)
Serving the Dry Goods Trade generally; Wholesale, Retail, Manufacturing and Department Stores. Published monthly.

Men's Wear Review (Est. 1898)
Serving the Manufacturers of Clothing, Underwear, Shirts, Collars, Neckwear, Footwear, Hats and Caps and Allied Sundries, and their Retail Distributors. Published monthly.

Canadian Machinery (Est. 1905)
Serving the Machinery, Metal-working, Iron and Steel, Foundry and Allied Trades. Published weekly.

The Power House (Est. 1907)
Serving the Operating and Consulting Engineers and Power Superintendents. Devoted to the Generation, Transmission and Application of Steam, Gas, Electric, Air and Water Power; and to the operation of Refrigerating Machinery. Published monthly.

Bookseller and Stationer (Est. 1884)
Serving the Book, Stationery, Fancy Goods and Associated Trades. Published monthly.

The Sanitary Engineer (Est. 1907)
Serving the Manufacturers of Sanitary, Heating and Ventilating Machinery, Systems and Equipments, and those installing them. Published semi-monthly.

Marine Engineering of Canada (Est. 1910)
Serving the Marine Engineering, Merchant and Shipbuilding Trades. Published monthly.

Canadian Foundryman (Est. 1909)
Serving Foundries and the Pattern-making, Plating and Polishing Trades. Published monthly.

Printer and Publisher (Est. 1892)
Serving the Publishing, Printing, Paper-making and Allied Trades. Published monthly.

The Financial Post (Est. 1907)
Serving the Business, Investment and Financial Interests of Canada. Published weekly.

MacLean's Magazine (Est. 1896)
A popular family and literary magazine; the most important in its field in Canada. Published monthly.

The Farmers' Magazine (Est. 1910)
Serving the agricultural and rural communities of Canada. The only farm and country life publication in Canada having extensive national circulation. Published semi-monthly.

This fact may interest you: namely, the MacLean organization is the largest concern of its kind in the British Empire. The output of its mechanical department every working day is the equivalent of a 125-page publication of the size and type of this copy of *Power House*.

Our London Office, 88 Fleet Street, E.C.

Also at New York Boston Chicago Montreal Winnipeg

For over 20 years the MacLean Publishing Company has maintained a fully-staffed London office, and has rendered British and Continental manufacturers, shippers, and traders an invaluable service in many directions.

Showing machine in filling position.

Showing machine in discharging position.

Use Your Condensation

Feed it to your boilers

MUCH HOTTER THAN PUMPS WILL HANDLE IT

Morehead Back to Boiler SYSTEM

Saves coal—stops sluggish circulation—and works steam heated equipment at top capacity

What are you doing with your condensation? Are you letting it cool down to accommodate a pump, and thereby wasting valuable heat units?

If you are the Morehead Back to Boiler System will more than pay for itself the first year.

Automatically the Morehead System picks up every bit of the condensation which is now allowed to clog in your steam lines—and rushes it right back to the boilers while it is hot, for use over again in the production of steam.

Every heat unit saved means a saving in fuel.

The Morehead System will enable you to produce more steam from less coal—and boosts production by keeping the steam lines constantly drained of all condensation.

MOREHEAD TRAPS are being used everywhere on heating, drying and cooking propositions of every kind from straight pipe work to fan stacks and under vacuum conditions, without regard to the difference in pressures between the apparatus drained and that carried on to the boiler and **without regard to location of the apparatus drained, whether above or below the water line in the boiler.**

Write us your conditions, and we will have our engineers study the situation in your plant, and give you some very valuable advice absolutely free.

Machines specially built for either high or low pressures and absolutely guaranteed.

Ask for catalog.

There's no guesswork about the Johns-Manville Underground System of Insulation

IT is the most definite system of underground distribution there is. Definite because its efficiency is known to be 90% or more based on the saving over bare pipe. Definite, too, because every detail in underground transmission practice has been met in the structural details of its design and in the materials employed.

We do not argue that there are no other systems that will transmit steam or other fluids underground but we can prove to anyone interested that for mechanical durability, maintenance and thermal efficiency and from an investment viewpoint it is the system where a dollar spent goes furthest in ultimate economy. Write for the booklet that gives all the facts.

The Canadian H. W. Johns-Manville Co. Limited

Montreal Toronto Vancouver Winnipeg
Hamilton London Ottawa

Different from all other steam traps

THE Johns-Manville Steam Trap has just three parts —body, discharge bushing, and ball; only one moving part, the ball. No complicated mechanism to adjust or repair—no air binding, no steam leakage. Controlled not by levers and counterweights but by unchanging physical laws, this trap is sure and continuous in operation and practically foolproof.

The details are interesting—just write for the steam trap bulletin. Or better yet, test a trap out for yourself—it is the best way we know of selling them.

Becoming a Bigger Man

WHAT is the difference between some men you know and others known to you? Why are some men earning $3,000 a year and some $30,000? You can't put it down to heredity or better early opp ortunities, or even better education. What, then, is the explanation of the stagnation of some men and the elevation and progress of others?

We are reminded of a story. A railroad man, born in Canada, was revisiting his home town on the St. Lawrence River. He wandered up to a group of old-timers who sat in the sun basking in blissful idleness. "Charlie," said one of the old men, "they tell me you are getting $20,000 a year," "Something like that," said Charlie. "Well, all I've got to say, Charlie, is that you're not worth it."

A salary of $20,000 a year to these do-nothing men was incredible. Not one of the group had ever made as much as $2,000 a year, and each man in the company felt that he was a mighty good man.

Charlie had left the old home town when he was a lad. He had got into the mill of bigger things. He developed to be a good man, a better man, the best man for certain work. His specialized education, joined to his own energy and labor sent him up, up, up. To put it in another way: Charlie had always more to sell, and the world wanted his merchandise—brain, skill and ability. Having more to sell all the time, he got more pay all the time.

Charlie could have stayed in the old home town; could have stagnated like others; could have been content with common wages. In short, Charlie could have stayed with the common crowd at the foot of the ladder. But Charlie improved himself and pushed himself, and this type of man the Goddess of Fortune likes to take by the hand and lead onward and upward. Almost any man can climb higher if he really wants to try. None but himself will hold him back. As a matter of fact, the world applauds and helps those who try to climb the ladder that reaches towards the stars.

The bank manager in an obscure branch in a village can get out of that bank surely and swiftly, if he makes it clear to his superiors that he is ready for larger service and a larger sphere. The humble retailer can burst the walls of his small store, just as Timothy Eaton did, if he gets the right idea and follows it. It is not a matter of brain or education so much as of purpose joined to energy and labor. The salesman or manager or bookkeeper or secretary can lift himself to a higher plane of service and rewards if he prepares himself diligently for larger work and pay. The small manufacturer, the company director, the broker—all can become enlarged in the nature of their enterprise and in the amount of their income—by resolutely setting themselves about the task of growing to be bigger-minded men.

Specialized information is the great idea. This is what the world pays handsomely for. And to acquire specialized information is really a simple matter, calling for the purposeful and faithful use of time. This chiefly.

One does not have to stop his ordinary work, or go to a university, or to any school. One can acquire the specialized information in the margin of time which is his own—in the after-hours of business. Which means: If a man will read the right kind of books or publications, and make himself a serious student at home, in his hours—the evening hours or the early morning hours—he can climb to heights of position and pay that will dazzle the inert comrades of his youth or day's work.

IF business—BUSINESS—is your chosen field of work, we counsel you to read each week THE FINANCIAL POST. It will stimulate you mentally. It will challenge you to further studious effort. It will give you glimpses into the world of endeavor occupied by the captains of industry and finance. With the guidance of the POST, and with its wealth of specialized information, you, a purposeful man, aiming to go higher in life and pay, will find yourself becoming enlarged in knowledge and ambition, and will be acquiring the bases and facts of knowledge which become the rungs of the ladder you climb by.

It is the first step which costs. But this cost is trivial—a single dollar. We offer you the POST for four months for a dollar. Surely it is worth a dollar to discover how right we are in our argument. If yoou have the will to go higher in position and pay, sign the coupon below.

THE MACLEAN PUBLISHING COMPANY, LIMITED,
—143-153 University Avenue, Toronto.

Send me THE FINANCIAL POST for four months for one dollar.

Money to be enclosed remitted

Team Work

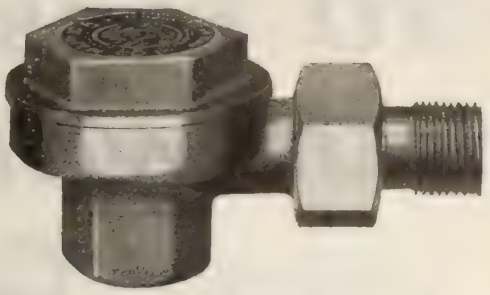
The boiler room and the office must work together to save coal. Proper firing, soot-free boilers, leak-proof packings—all these help. But this good work is offset when the heating system is clogged up with air and water. Then, a hotter fire only makes the system pound and knock—and lowers the coal pile instead of raising the temperature. Suggest to your employer that Dunham Radiator Traps be used.

The DUNHAM HEATING SERVICE

C. A. DUNHAM CO., LTD., TORONTO, CANADA

Branch Offices:

Halifax Montreal Ottawa Winnipeg Vancouver Calgary



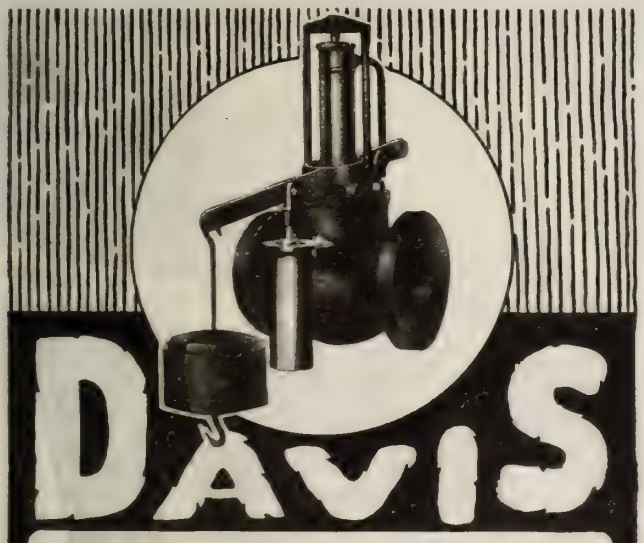
The Dunham Radiator Trap

is furnished with special roughing in measurements to replace imitating devices.

GIVES STEAM A CHANCE TO CIRCULATE

By automatically relieving the radiator of the air and water, the Dunham Radiator Trap removes the back pressure so that the steam can circulate freely through the entire radiator. Less coal is required to put the steam through the system—and all radiators heat up **noiselessly.** The simplicity of the Dunham Radiator Trap makes it possible to change over existing installations without extensive alterations.

Send for all the details now!



DAVIS

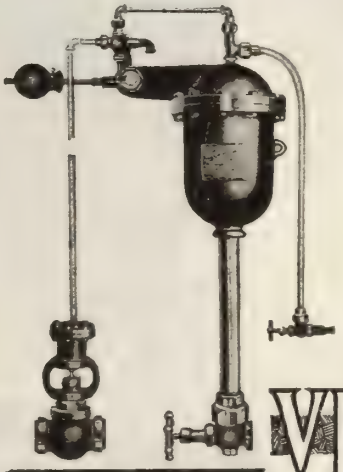
Pressure Regulators

are trouble-savers as well as steam-savers. They automatically reduce any pressure—steam, air or water—to any desired lower pressure. No springs, no diaphragm, no delicate parts—just a steady, sturdy reducing valve that can be relied on at all times and under all conditions.

Write for the new Davis booklet showing the pressure regulator and all the other Davis Steam Savers. Address the G. M. Davis Regulator Co., 434 Milwaukee Ave., Chicago. Branches in principal cities.

DAVIS VALVE SPECIALTIES

STEAM SAVERS SINCE 1875



Keeps the Water Within ¼" of Middle Gauge

This VIGILANT

Automatic Feed-Water Regulator

It does precisely **that,** automatically, perfectly, regardless of the load or firing. Therefore it is a positive protection from all high and low water accidents.

Incidentally—and this we can also prove—the Vigilant Feed-water Regulator saves 3 to 17 per cent. on fuel costs.

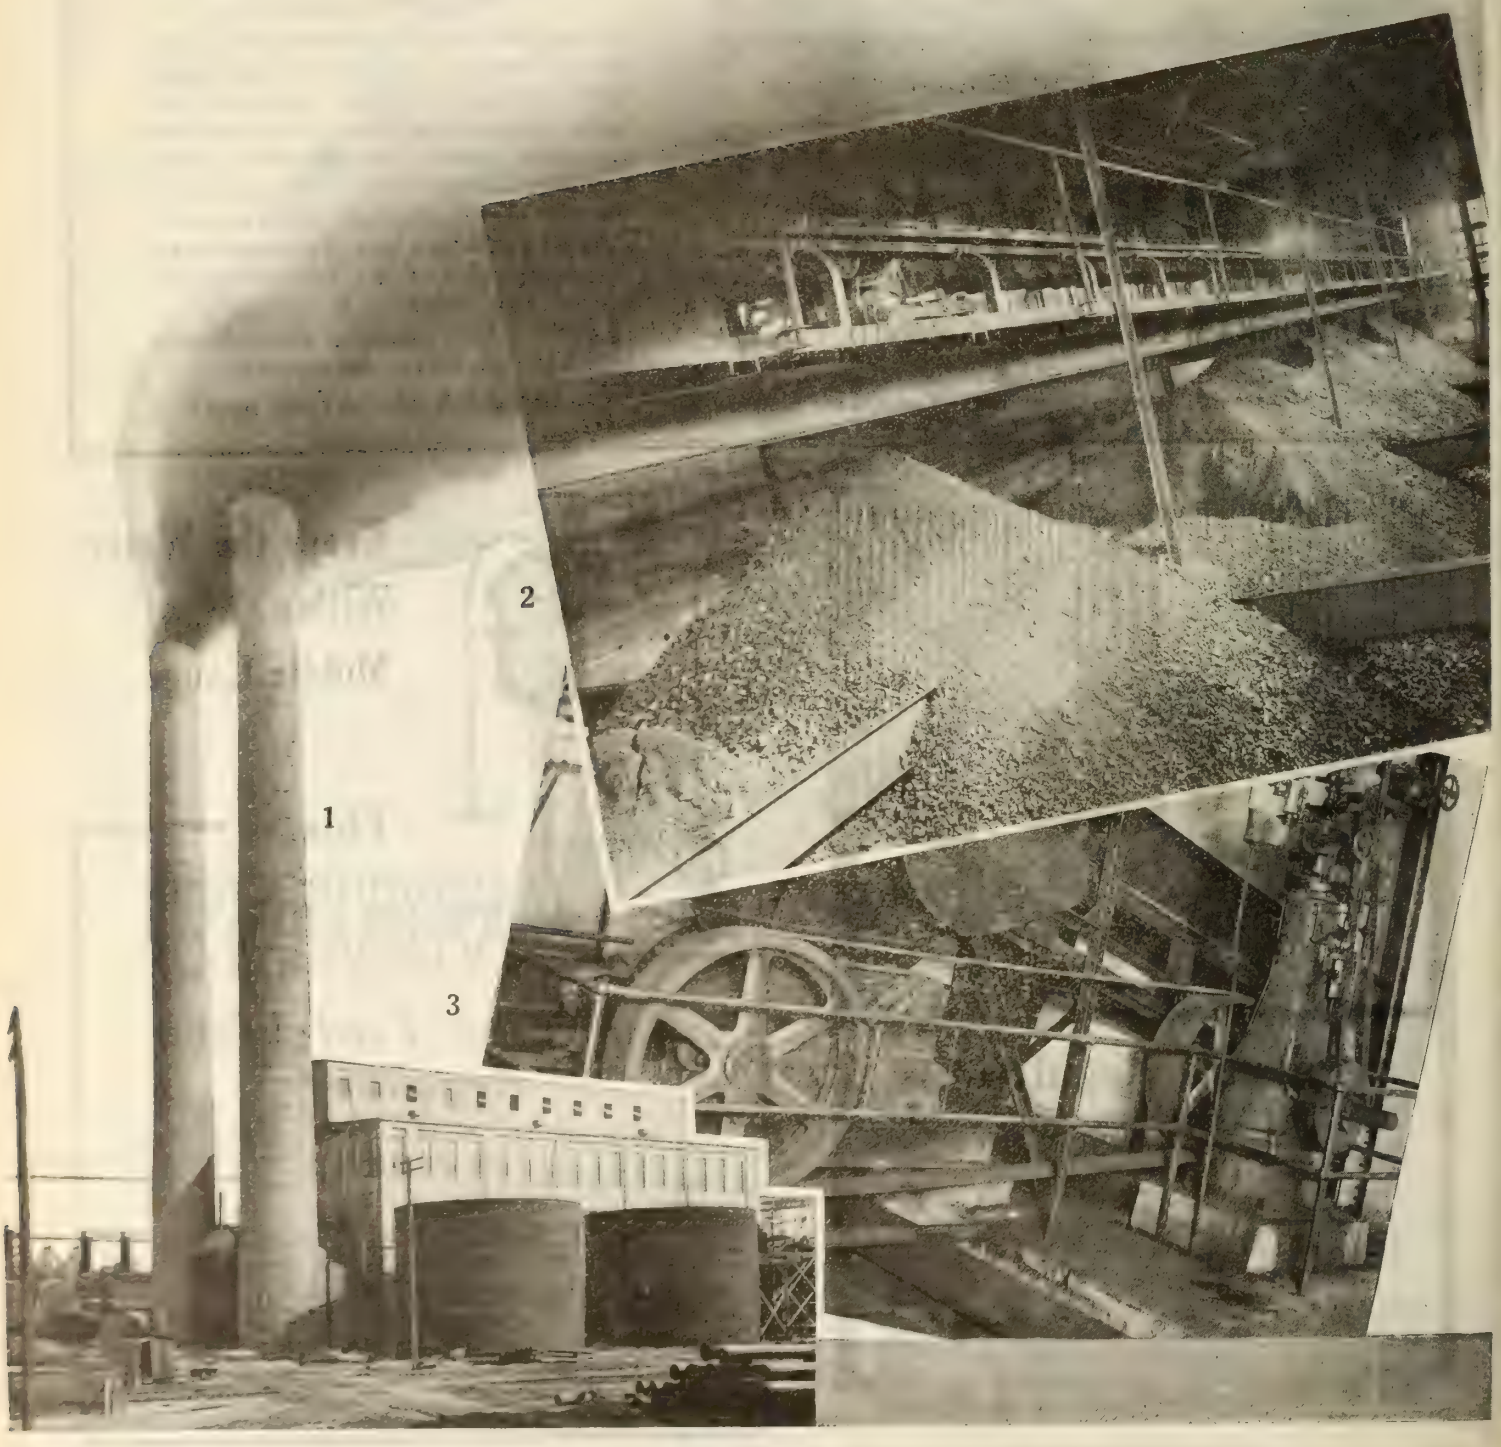
70 Tons of Coal Per Hour with the Jeffrey Carrier



"The Jeffrey System will Solve Your Coal and Ash Handling Problems"

1

The new power plant of the Solar Refining Company, Lima, Ohio, where a Jeffrey 24-in. x 24-in. Carrier is handling about 70 tons of crushed coal per hour. The vertical lift is 66 ft. while the horizontal run is 107 ft. Only 8 to 10 horsepower required for full capacity of carrier.

2 Showing the upper run of the Carrier at the Solar Plant. Note the readily adjusted Traveling Tripper. The bucket design gives greatest capacity for complete discharge of material with minimum wear and shock.

3 The lower run of the Carrier showing a Jeffrey 30-in. x 30-in. Single Roll Crusher which delivers a uniform product to the Carrier for the stokers.

The New Jeffrey Carrier will solve your Coal and Ash Handling problem and save money at the same time. War-time wages and labor scarcity make the present time especially appropriate for labor conservation. Let us convince you of the merits of the Jeffrey Carrier.

Bulletin No. 237 will give you complete data on the New Jeffrey Carrier. It gives detail views that prove Simplicity and Rugged Construction and shows many important installations.

Write NOW for your copy.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID, Minister of Public Works and Highways
W. A. RIDDELL, M.A. Ph.D., Supt. Trades & Labour Branch

D. M. MEDCALF,
Chief Inspector of Steam Boilers.

There's a Big Waste in Little Leaks

Do you know that a one-tenth inch pipe-joint leak at 150 lbs. pressure will waste steam in a year at a cost to-day of approximately $825? Figure it out for yourself. Leak one-tenth inch; pressure 150 lbs.; 9 lb. steam per lb. coal; coal $5.50 ton; 10 hours per day; 300 days per year.

And it's such an unpatriotic waste in these days of coal conservation—such a needless and careless waste at any time—for the leak can be stopped in a few minutes' time with a YARWAY (formerly Simplex) PIPE JOINT CLAMP.

More than 13,000 leaks have been stopped since this effective clamp was first placed on the market. Millions of dollars have been saved. The saving in coal can only be guessed.

The Yarway (formerly Simplex) can be attached in a few minutes by any workman. The principle can be seen from the illustration shown here.

If there is a pipe-joint leak in any of your lines, tell us the size and we will send you a Yarway for 30 days' trial. Instead of returning it, you will probably be as enthusiastic over its success as the man who said of a Yarway Clamp, "It's worth its weight in gold."

Winnipeg, Man.—Galt Bldg. **Calgary, Alta.—211 Eighth Avenue W.**

That belt must be slipping, George! It's too loose on the pulleys!"
No it isn't, Uncle. If it slipped at all, it wouldn't stay on the pulleys a minute!"

THE new Superintendent was different. For the first few days he just walked through the plant and looked at things. Down in the engine room he took the speed of the engine. Up in the shop he took the speed of the main shaft. Then he did some figuring. These are the figures:

Driving pulley 8 feet diameter.
Speed 80 rev. per minute.
Driven pulley 4 feet diameter.
Speed should be 160 rev. per minute.
Speed actually.. 155 rev. per minute.
Loss ..... 5 rev. per minute.
5 ÷ 160 = 3% approximately.
8 ft. × 3.1416 × 80 rev. per minute = about 2,000 feet per minute the belt travels.
3% of 2,000 feet = 60 feet per minute LOST.
Pulley centres at 20 feet, so belt length approximately 60 feet.

This meant that once every minute his belt was useless, **for the loss in feet per minute due to slipping was more than the length of the belt itself!**

In a ten-hour day this loss would be 36,000 feet, so that every day the engine had to give that belt a free ride of nearly 7 miles! And the firm paid the bills at the coal pile and machines, at the bearings, pulleys and in the belt itself. It didn't look right.

The plant had over one hundred belts. If they all slipped, the firm must be losing hundreds of dollars a year in power, time and equipment which might better be saved

* * * * * *

The new Superintendent never did things on impulse, or merely on someone else's say-so. Back in his experience he had **used** CLING-SURFACE, the treatment which PREVENTS SLIPPING, and allows the usual drive to be run easy or slack under full load. He knew that it makes constant tension unnecessary, preserves and makes the belts thoroughly pliable and waterproof; that it is not sticky, contains no rosin or anything harmful, and is safe, easy and economical to use.

So he had every belt treated, and the effect was seen at once. His slipping stopped, he had more and steadier power, and not a belt has been taken up since that time.

This is fact; we can prove it on your drives to YOUR satisfaction. Just ask for THE PLAN 10,000 firms have found

And remember, use CLING-SURFACE and you won't need belt dressings.

1057 Niagara Street
Buffalo New York

John Crane

Accurately cut rings for large rods, plungers, etc.

How "John Crane" SOFT FLEXIBLE METALLIC PACKING IS MADE

"John Crane," you see, is DIFFERENT, is FAR BETTER, is more SCIENTIFICALLY constructed and is more PRACTICAL than the shredded, braided, twisted, granulated, shot, poured and segmental types of metallic packing.

Engineers all over the country are rapidly adopting, approving and recommending "John Crane" as STANDARD EQUIPMENT.

If your rods are NEW "John Crane" will KEEP them new. If they are GOOD—"John Crane" will KEEP them good. If your rods are BAD it is a sure sign that they are NOT packed with "John Crane."

Write for our demonstration proposition, made entirely at our own risk.

TRADE MARK

MAGNOLIA ANTIFRICTION METAL

TRADE MARK

FOR MOTOR BEARINGS

INTERNATIONAL UNION OF STEAM AND OPERATING ENGINEERS
Local Union No. 20

New York, April 20, 1918.

Magnolia Metal Company, New York, N.Y.

Gentlemen:—I have been chief engineer of the Metropolitan Realty Building, 216-218 William Street and 18-20 Rose Street, New York City, from February, 1898, to May, 1912, during which time I have always used MAGNOLIA METAL. Previous to my using MAGNOLIA METAL I always had trouble with bearings on motors throughout the building. They were continually wearing out with the result that the armature of heavier motors pulling up against the pole piece which necessitates re-babbitting of bearings. I re-babbitted the bearings on all motors with MAGNOLIA METAL—some of these motors are running night and day for practically over fifteen years, and what was especially remarkable on my recent visit to the building was the fact that the 50-horsepower motors which drove line shafts by heavy double belting showed no noticeable wear and bearings were in perfect condition just as they were fifteen years ago.

I also had main and outboard bearings of Fishkill Landing Corliss Engine, which is 300-horsepower, re-babbitted in 1901—said engine has run every day since that time, and find main bearings, quarter boxes, etc., in perfect condition to-day.

I can, therefore, justly testify to the value of MAGNOLIA METAL.

Very respectfully yours,
M. MURPHY,
Business Representative, Engineers Local No. 20

ELECTRICAL SAFETY AND ECONOMY

ECONOMY
Renewable
FUSES

Cut Annual Fuse Maintenance Cost 80%

Economy "Drop Out" Renewal Links are responsible for this saving.
A "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.
A sustained arc is impossible.
It's the work of a moment for even a novice to replace the link and renew the fuse.
First in its field—first in efficiency.
Order from your dealer.
Write for Catalogue 24.

SCANDINAVIA BELTING

For Belt Conveyors

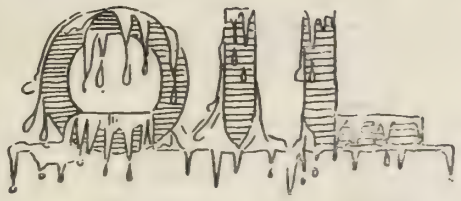
This belt will give good and long service as a conveyor and can be kept continually in service until the whole fabric is worn out. This solid woven belt does not fall down when its work is only partly done by the plies opening up—there are no plies and no joints.

This belt is particularly well adapted for carrying broken stone, ore, coal, quenched coke, etc. We can refer to large plants who have been giving repeat orders for this belting for years, having found this the most satisfactory material.

When you need a new belt for your conveyor please let us have the opportunity of quoting.

Federal Engineering Co., Limited
172 John Street - TORONTO

USED



Made Pure and Clean

Made so clean and so pure that you can use it over and over on the finest bearings, every drop preventing friction—none wasted.
In this way will the

ANDERSON
Pressure Filter

many times return its cost. For actually more than half of all the oil you buy is saved instead of wasted—once you have this Anderson Pressure Filter to cleanse and purify the used oil in the one effective way—the way refineries treat crude oil.

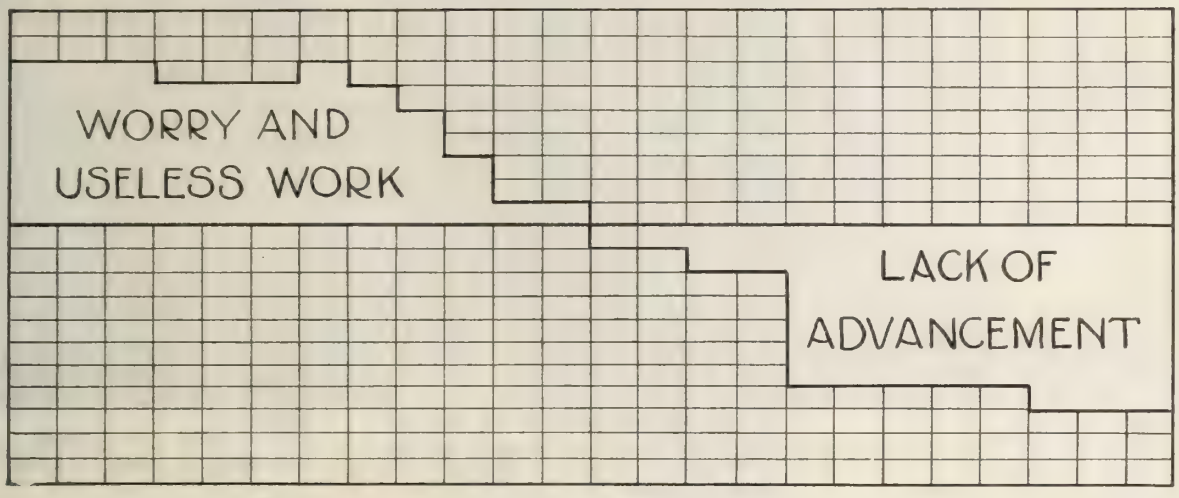
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary,

Canadian Association of Stationary Engineers

230 Caroline Street Hamilton, Ont.

Power Plant Equipment Co., Dominion Bank Building **Toronto, Ont.**

Albany Grease

has just rounded out a half century of usefulness. Its incomparable record of lubrication service during the past 50 years stamps it as a most efficient and economical lubricant. For

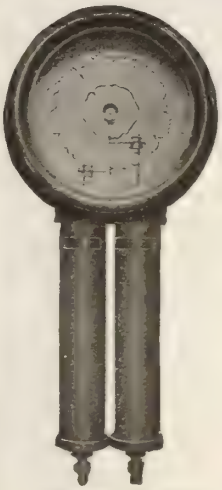
50 YEARS

Albany Grease has been used by engineers on the bearings of engines, motors, pumps, compressors, line shafting and all their other equipment. If you are not using Albany Grease send for samples and try it.

ALBANY LUBRICATING COMPANY
708-10 Washington Street
NEW YORK, U.S.A.
Established 1868

UEHLING WASTE METER

COMBINED
CO_2 AND TEMPERATURE RECORDER



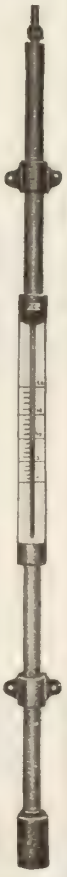
Record of CO_2 and stack temperature on one chart.

Does your fireman know how much fuel he is wasting? Do you know?

The **Uehling CO_2 Recorder** makes a complete 24 hr. record of your combustion efficiency and the **CO_2 indicator at the Boiler Front** holds the fireman responsible.

Get more **Steam** per pound of **Coal** and reduce your annual fuel consumption.

Let us know the number and size of your boilers and coal consumed per year, upon receipt of which information we will be glad to send you full particulars.



CO_2 Indicator for Boiler Front

Let us hear from you. We are pioneers in the manufacture of Indicators and Recorders for Power Plant purposes.

Send for our Bulletin No. 110.

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive **all** offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CAT ALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compre ssors, etc.**

MACGOVERN & COMPANY, Inc.

The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH

Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.

Nut with Nut-Guards

Photo shows Inglis Corliss Engine at Canadian Kodak Company's plant, Mount Dennis (near Toronto), Ont.

This ideal "Corliss" has cylinders 18 in. and 30 in. by 30 in. stroke, running at 150 r.p.m. It is direct connected to a 300 k.w. Canadian Westinghouse 3-wire, 125-250 volt, d.c. compound wound generator.

The Engine operates at a steam pressure of 150 pounds, with 5 pounds back pressure. Valve Gear is operated by double wrist plates set for long range cut-off, the governor controlling both high and low pressure cylinders. Flywheel is 11 ft. in diameter and weighs 22,000 pounds.

Put your engine problems in our hands.

Firms big and small all through Canada are doing so with the best of results. Tell us of your special requiremeents and Inglis experts will go into the details immediately with you.

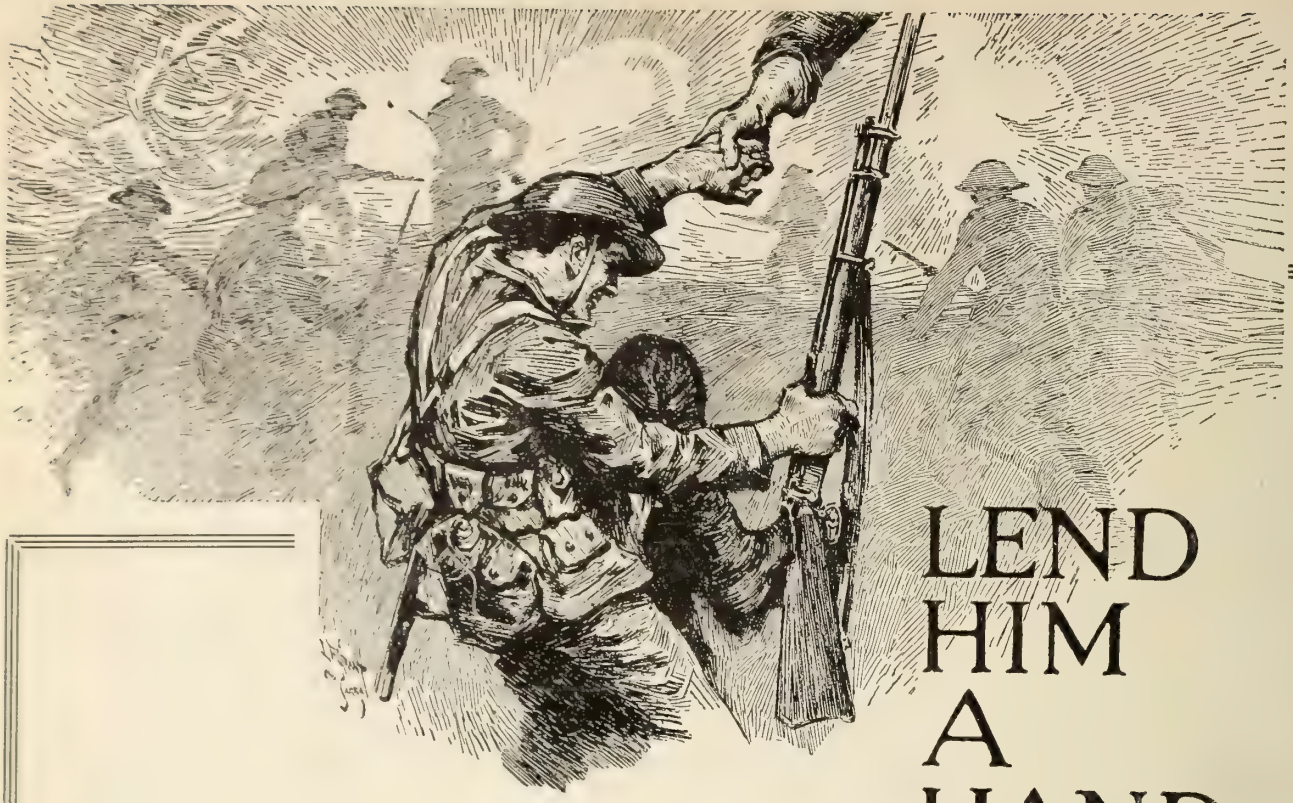
Boilers for all Services

INGLIS BOILERS have been successfully meeting all Canadian Industrial demands for over half a century. Built to last and give efficient and economical service.



LEND HIM A HAND

WE dare not delay the VICTORY now. Canadian lives are at stake, our own safety, the safety of the whole world. If we are not to prolong the slaughter and the suffering, if we are not to risk defeat, or an inconclusive peace, we must act quickly; we must put forth our every effort now.

The army is doing its part. We are going to do our share to maintain an army large enough so that, with our Allies, we can drive the German hordes back across the Rhine—so that we can win the decisive VICTORY that will make Canadian freedom safe, and establish a just and lasting peace.

But the whole nation must take part. Our army in France is looking to us to furnish it, in ever greater abundance, the ordnance, the munitions, the supplies that will make VICTORY possible. We must not fail.

The Victory Loan is our share in the winning of this war. Upon it depends the safety and success of Canadian soldiers in France.

Lend Him a Hand!
Buy! Buy! Buy Till It Hurts

POWER HOUSE

A monthly newspaper devoted to the Generation, Transmission and Application of Steam, Gas, Electric, Air and Water Power; and to the operation of Refrigerating Machinery.

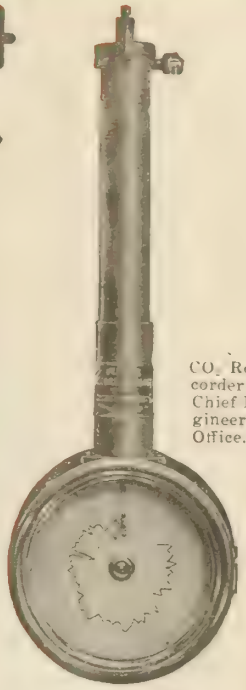
Published by The MacLean Publishing Company, Limited, 143-153 University Ave., Toronto

MONTREAL: Southam Bldg. LONDON, ENG.: 88 Fleet St., E.C. WINNIPEG: 1207 Union Trust Bldg.

Vol. XI—No. 10 Publication Office, Toronto—November, 1918 Published Monthly $1.00 per Year.

Bring Down Your Steam Cost In Spite of High Coal Prices

With coal prices soaring away above the normal and with coal harder to get then ever before, you are facing a critical situation.
Coal must be saved without curbing your steam output. You can do this only by abolishing preventable fuel waste in the boiler room.
Continuous knowledge of the heat wasted up the chimney is the first essential toward establishing better combustion.



CO_2 Recorder for Chief Engineer's Office.

UEHLING CO_2 Recording Equipment

offers a direct and absolutely reliable means for detecting heat waste by indicating and making 24-hour chart records of the percentage of CO in the flue gases.

The operation is positively continuous and not intermittent.

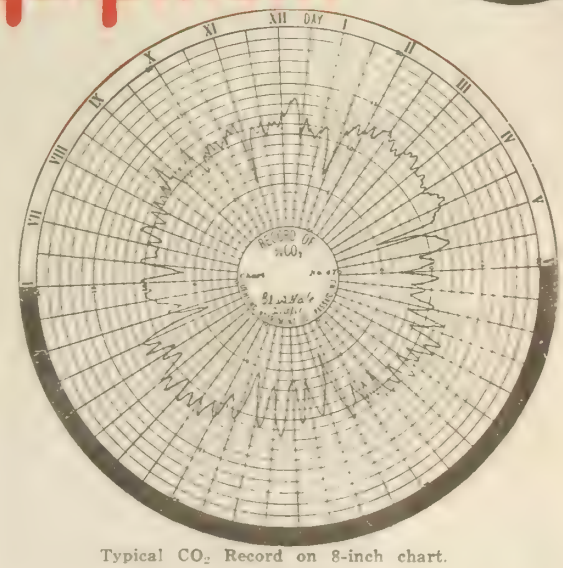
The recording gauge may be mounted in your office or elsewhere at a distance from the machine.

The indicator serves as a guide for the firemen in the boiler room.

The charts also serve to show the time taken for cleaning fires, the number of times and how long the fire doors were left open and how often the men fired.

Do you wonder why Uehling CO_2 Equipment has enabled so many engineers to reduce their steam coal?

Uehling CO_2 Meters and Combined CO_2 and Temperature Machines are made up in various styles and combinations to meet any requirement. Our engineers are ready to take up your combustion problem now. W



Typical CO_2 Record on 8-inch chart.

ENGINEER WILLIAM WILLIAMS

of the Power House Staff of the McCormick Mfg. Co., London, Ont.,

Using The "Dean"

The McCormick Factory is one of the finest of its kind on the continent and the Dean Cleaner has been employed as a factor in the efficiency of this splendid organization.

The Dean Cleaner has proven its ability to take out scale faster and more thoroughly than any other type of tube cleaner, due largely to the absence of all intricate cutting and boring parts, and its sturdy simplicity which make for a long life, a low upkeep cost, and ease of operation.

You can use the "Dean" interchangedly in fire and water-tube boilers and different sizes of tubes.

Every Barrel of BOICO The Quick Remover and Positive Preventive of Boiler Scale

SAVES A PILE OF COAL

It's such a heartless job trying to keep a boiler clean with ordinary compounds that comparatively few are always wholly clean. Consequently a good deal more fuel than need be is turned up on the grates. We claim for Boico that it removes absolutely all scale; that it positively prevents further formation of scale; that it does not carry over in the steam; that it does not cause foaming or priming; that it does not injure packing or valves in the slightest. You do not pay for Boico if it fails.
Write for our trial offer.

Anti-Clinker Shell Bar Grates

save coal. For one thing they prevent clinker formation. Half this total surface is air space—and abundant air commands perfect combustion. Let us tell you more in detail.

A DIRECT CONNECTION

LUBRICATION always has a direct and important relation to production costs. Proper lubrication reduces upkeep as well as operation costs. Proper lubrication means a greater output, less repair bills and more years of service from power plants and other machinery.

Correct lubrication requires not only high quality lubricants but **carefully selected lubricants.** To properly lubricate your plant you must use the right lubricant for each specific purpose. Do not let poor lubricants or improper lubrication destroy expensive machines before their time. Imperial lubricants are always cheaper in the long run. There is indeed a direct connection between lubrication and your cost account book.

Our Lubrication Engineers will gladly advise you on anything relating to lubrication. Write us at 56 Church St., Toronto. All enquiries will receive prompt attention.

Cyclone Grates

Their 60% air space and 90% under-draught insure positively perfect combustion, whether the fuel used is screenings, soft coal or the highest grade hard coal. Their use means that all the energy locked in fuel will be freed and utilized to make steam.

There's no clinker formation, no good fuel lost in the ash pit, no waste whatever where Cyclone Improved Shaking and Dumping Grates are used. Cyclone Grates can be installed without delay or trouble. And we've a 30-day trial offer that you should know about.

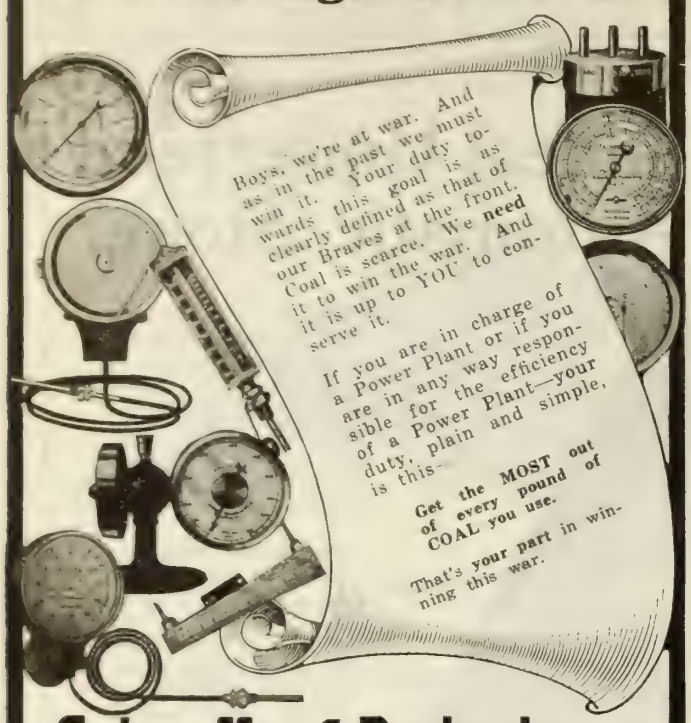
A Message to YOU



Boys, we're at war. And as in the past we must win it. Your duty towards this goal is as clearly defined as that of our Braves at the front. Coal is scarce. We need it to win the war. And it is up to YOU to conserve it.
If you are in charge of a Power Plant or if you are in any way responsible for the efficiency of a Power Plant—your duty, plain and simple, is this—
Get the MOST out of every pound of COAL you use.
That's your part in winning this war.

The Webster Vacuum System of Heating

can be likened unto the Matterhorn. It has an individuality all its own. From its pinnacle of fame it commands everything in sight.

The Webster System cannot be anything but a good system because of its simplicity and excellence of operation.

It is a **Vacuum System,** which means, crudely, that steam leaving the boiler is sucked through the radiation, no matter where placed, and made to perform its functions to the last ounce.

But the real beauty of the thing is this: Your heating, or a large part of it, can be taken care of by the use of **Exhaust Steam from your Boiler. Think of it,** steam that you would otherwise waste can be developed into heating units by the use of the **Webster Vacuum System of Heating.**

Help Solve A National Problem

Coal is scarce. It is an essential war commodity, and patriotism and humanity call for its conservation. There is a need for national effort in this direction and every industrial plant that uses coal should adopt every economic method available for saving this precious fuel.

Coppus Turbo Blowers, Type "C"

places in the reach of every power house and industrial concern that uses coal an opportunity to effectively combat the fuel problem.

You can increase your present steaming capacity to 200 and even 300% of the normal rating of the boilers without injury to the boilers.

Coppus Turbo Blowers give you more power, better p from less and cheaper coal.

You will have all the steam you want all the time. Hundreds of satisfied customers will attest to this. No drop in steam pressure when a heavy load comes on and you can laugh at the weather man as he varies the draft in your chimney.

Conditions favor the adoption of Coppus Turbo Blowers now as never before. They will not only help **you** but will also help **your country** to solve a national problem. **Write for the full story of "Coppus" efficiency without delay—it will pay you.**

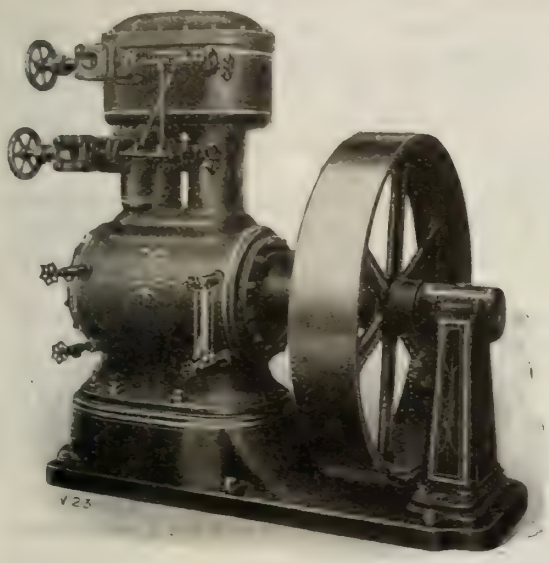
Ice-making and Refrigerating Machinery

Built in any capacity that you desire. HORIZONTAL OR VERTICAL
Our SMALL MACHINES have the same "regularity of Operation," "Reliability" and "Efficiency" as our large ones.
AMMONIA FITTINGS, CONDENSERS, BRINE COOLERS, ETC.

Our Machines are in daily operation in Canada
CORLISS and POPPET VALVE ENGINES

The Vilter Manufacturing Company
242 Beecher St. - - - Milwaukee, Wisconsin

FRICK Machines "Carry On"



It is a fact that FRICK Machines have been "Carrying On" for more than thirty years, meeting all attacks and conditions encountered in every-day operation, especially during the busy season, when overloads and extra duty are of common occurrence.

"We are practically running our cold storage plant just as you installed it eighteen years ago ; we added a twelve ton fish sharp freezer some dozen years ago, and added four rooms for fruit from time to time, and the machinery installed keeps all running in good shape. Our cost for maintenance and repairs during all these years has been very small, and the machinery looks good for another eighteen years."

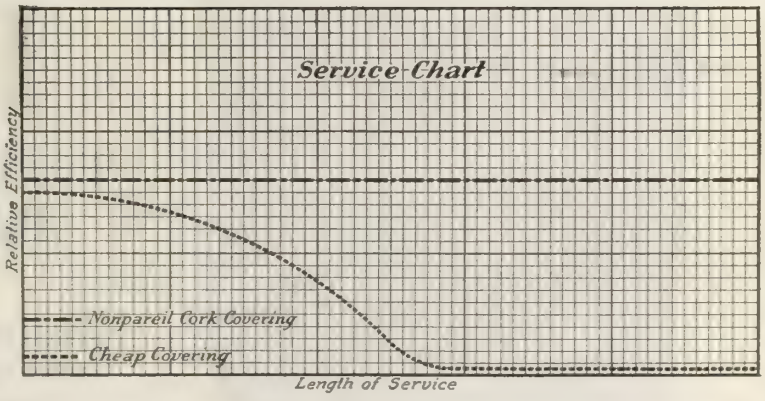
Frick Company
WAYNESBORO, PA. U.S.A.
ICE MACHINERY SUPERIOR SINCE 1882
BRANCHES IN ALL PRINCIPAL CITIES

There is a FRICK Machine for every refrigerating purpose—all types: Vertical — Horizontal — Absorption.

Efficient? Yes. But for How Long?

How long will cold pipe covering last without losing its initial efficiency? This is one of the most essential points to consider when buying cold pipe insulation.

Water vapor is present in the atmosphere at all times. And coverings that are fibrous in structure, even though they may have a waterproof coat, will soon begin to suck in moisture by capillary attraction. Under such conditions they gradually become watersoaked and in a short time their value as insulation is almost nil.



Nonpareil Cork Covering is not only efficient in stopping refrigeration loss to begin with, but it possesses no capillary attraction. Its minute, sealed air-cells are impervious to moisture. Hence the covering keeps dry and retains its original efficiency for many, many years.

Even if the first cost of Nonpareil Covering is a little more, its additional years of efficient service make it by far the cheapest in the long run.

Nonpareil Cork Covering
For All Cold Pipes

Armstrong Cork & Insulation Company
504 McGill Building, Toronto, Ontario, Canada

Also manufacturers of Nonpareil Corkboard Insulation for all cold storage rooms.

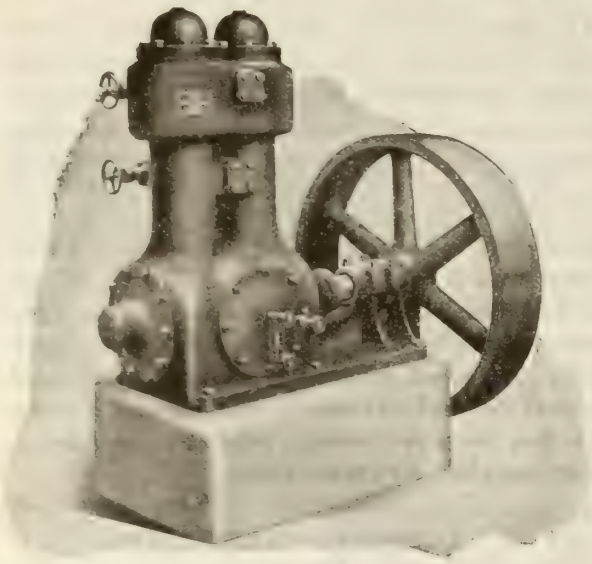
Refrigeration—A National Demand



The nation-wide appeals for the conservation of food products is greatly increasing the demands for mechanical refrigeration. Ice-making and Refrigerating Plants all over the country are overhauling and improving their equipment so that they may supply this demand and reap the increased profits.

Quality in refrigerating machinery, under present conditions, is more to be valued than ever before. An interruption of operation will mean a definite loss.

York Ice-making and Refrigerating Machinery is known universally as the Standard. There's a York Machine to meet every practical condition of mechanical refrigeration, and we are always ready to advise with prospective customers concerning their requirements and then to furnish the plant best suited to meet his conditions.

Let Our Engineers Help You. Write us about your problem.

DOORS

For Cold Storage and Freezer Purposes Either Standard or Fireproof

JAMISON'S "JONES" and "NOEQUAL" doors are SUPERIOR because:

1st—Only the best materials are used in their construction.
2nd—We use heavier materials. Result: Longer life and increased efficiency.

3rd—Our doors are built with double and triple seals of contact—others have but one.

4th—Our Automatic Self-Tightening Fastener is the only truly AUTOMATIC and SELF-TIGHTENING Fastener on the market.

5th—Our ADJUSTABLE SPRING Hinges mean the door is always properly seated in the frame, making sagging impossible.

Write for General Catalog No. 7, illustrating and describing both "Jones" and "Noequal" doors, windows, ice doors and chutes, etc.

Books for the Engineer's Library

Hawkins' New Catechism of Electricity

It contains 550 pages with 300 illustrations of electrical appliances; it is bound in heavy red leather, with full gold edges and is a most attractive handbook for electricians and engineers. One-third of the book is devoted to the explanation and illustrations of the dynamo, with particular directions relating to its care and management—$2.10 post paid.

Engineers' Examinations

By N. Hawkins, M.E.

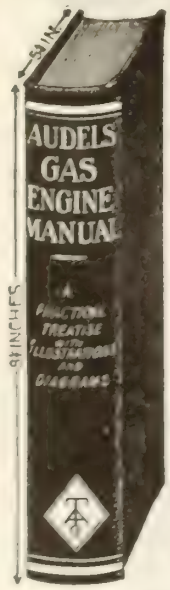
It presents in a condensed form the most approved practice in the care and management of steam boilers, engines, pumps, electrical and refrigerating machines with examples of how to work the problems relating to the safety valve, strength of boilers and horse power of the steam engine and steam boiler.—$2.10 post paid.

Steam Turbines

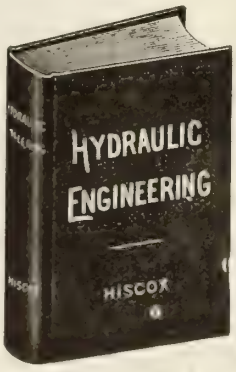
By Leland.

A reference work on the development, advantages and disadvantages of the steam turbine; the design, selection, operation and maintenance of steam turbine plants and turbo-generators. 136 pages. Illustrated.—$1.00.

Audel's Gas Engine Manual



A practical treatise relating to the theory and management of gas, gasoline and oil engines, including chapters on producer gas plants, marine motors and automobile engines.—$2.00.



Hydraulic Engineering

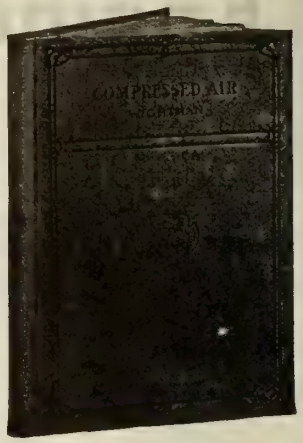
By G. D. Hiscox.

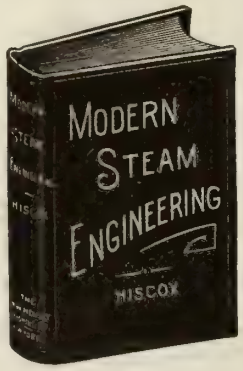
This comprehensive book of Hydraulics written by an experienced engineer, is a practical treatise on the properties, power and resources of water for all purposes, including the measurement of streams, the flow of water in pipes or conduits; the horse-power of falling water; turbine and impact water wheels; wave motors, etc. All who are interested in Water Works Development should have a copy. 320 pages, 305 illustrations. Price $4.15 post paid.

Compressed Air

By L. I. Wightman, E.E.

A reference work on the production, transmission and application of compressed air; the selection, operation and maintenance of compressed air machinery; and the design of air power plants. Illustrated.—$1.10.





Modern Steam Engineering in Theory and Practice

By Hiscox.

This book has been specially prepared for the use of the modern steam engineer, the technical students, and all who desire the latest and most reliable information on steam and steam boilers, the machinery of power, the steam turbine, electric power and lighting plants, etc. 450 pages. 400 detailed engravings.—$3.15 post paid.

Boiler Construction

By Kleinhans.

The only book showing how locomotive boilers are built in modern shops. Shows all types of boilers used; gives details of construction; practical facts, such as line of riveting punches and dies, work done per day, allowance for bending and flanging sheets and other data that means dollars to any railroad man. 421 pages, 324 illustrations, six folding plates.—$3.00.

Compressed Air, Its Production, Uses and Application. *By G. D. Hiscox, M.E.*

Comprising the physical properties of air from a vacuum to its liquid state, its thermodynamics, compression, transmission and uses as a motive power in the operation of stationary and portable machinery, in mining, air tools, air lifts, pumping of water, acids and oils and the numerous applicances in which compressed air is a most convenient and economical transmitter of power.—Price $5.15 post paid.

Boiler Accessories

By Walter S. Leland. S.B.

Assistant Professor of Naval Architecture, Mass. Institute of Technology, American Society Naval Architects and Marine Engineers. 144 pp., 80 illus. Cloth binding. A treatise giving complete descriptions of the various accessories of the boiler room and engine room essential to economical operation, such as evaporators, pumps, feed-water heaters, injectors, mechanical stokers, etc., with practical instruction in their use.—Price $1.10 post paid.

TORONTO NOVEMBER, 1918

What Do You Think About It?

IT is officially announced that Canada is to receive orders for millions of dollars' worth of material and supplies for reconstructing devastated Europe!

Mr. Lloyd Harris, Chairman of the Canadian Munitions Board in Washington, and Mr. Frank P. Jones, Chairman of the War Trade Board, Ottawa, are proceeding to England at once. Lloyd Harris has been instrumental in securing orders for millions of dollars' worth of munitions from Uncle Sam, and he can be counted on to get Canada's share of European reconstruction business. Mr. Jones is a team-mate worthy of his associate, and the pair, together with others who will be associated with them, can be relied upon to solve, in a large measure, some of the anticipated problems of the period of readjustment which was expected to follow the close of the war.

Then, too, the Railways are to have their innings, and their purchases of rolling stock and track equipment will keep our steel mills busy for some months.

The shipbuilding programme of the Government is to be carried out and possibly enlarged, and the industries which have suffered through lack of raw material and supplies will be able to catch up.

The world is forming into a vast bread line, turning with appealing eyes and outstretched hands to America. Our production of foodstuffs must be greatly increased, and there should be no unemployment so long as there is an acre of tillable land that is not producing.

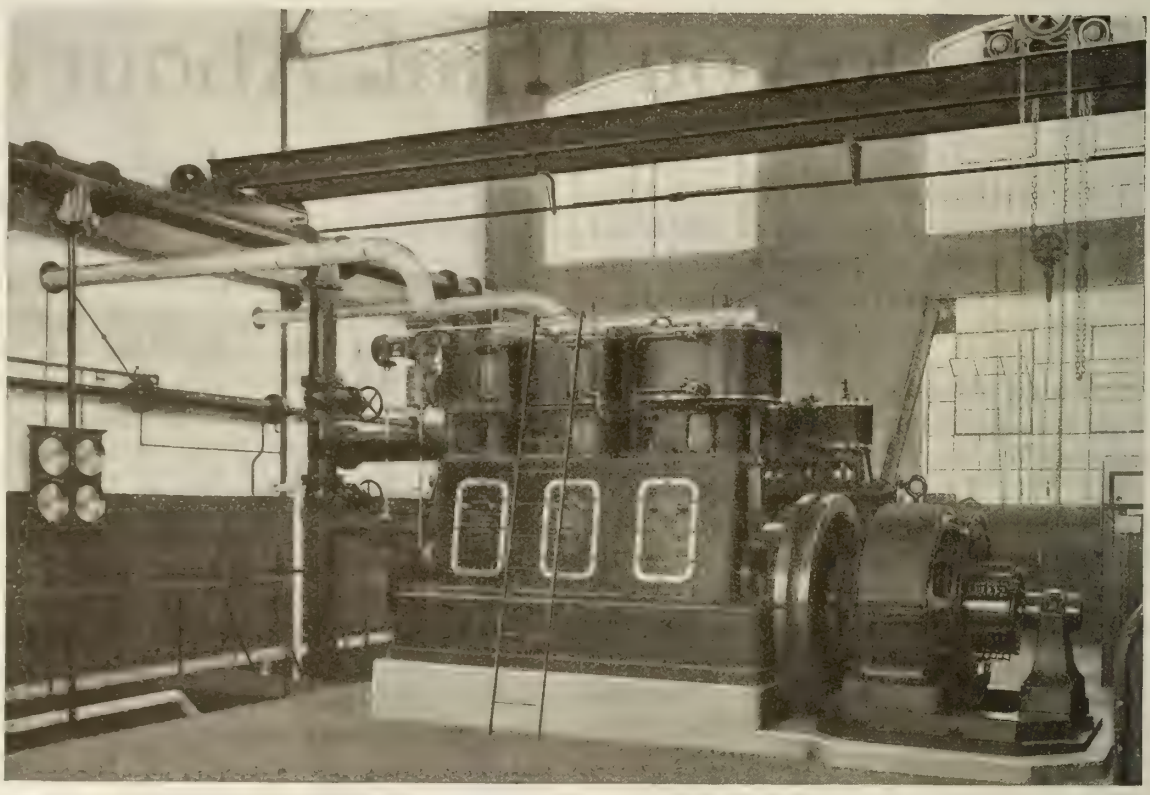
There were those who said that business would go to the dogs when the war broke out, and see what happened! There will be gloom spreaders rampant again, and if we would listen we would become gloomy too.

This is a time for balance, for good judgment and optimism, for clear thinking, initiative and action. It is a time for thanksgiving and not for gloom. For unselfishness, for charity of thought and not for greed and parsimonious profit protecting. It is a time for kicking old policies and old doctrines into the street if they stand in the way of doing the things which better judgment says should be done.

Two shadows never made a ray of light and pessimists didn't win the war. Let us take fresh courage and face the future with faith, hope and confidence. We're living in a better world!

POWER EQUIPMENT

Built to Meet Your Own Requirements



A corner in the Engine Room of our New Power Plant recently erected at our Main South Works. Equipped with G. & McC. Co. Three-Cylinder Compound and Two-Cylinder Compound Vertical Forced Lubrication Steam Engines.

POWER HOUSE

The Historical Development of Steam Turbine I.

The Beginning of a Series Treating of the History of the Turbine From An Engineering Standpoint—Early Progress—Charles A. Parsons—American Development

ROUGHLY speaking, the whole of the development of the steam turbine has occurred within thirty years. This is a very brief period as compared with the development of the reciprocating engine, which occurred over a period of more than ninety years. Many are inclined to attribute this to the high technical skill and scientifical attainment of the present age, but a more true reason than this is the fact that metallurgical and manufacturing arts were available for the turbine manufacturer which were not available for the early builders of steam engines.

Early Progress

A cursory review of the British Patent Office records in the early years, say 1800 to 1850, show them to be rich in turbine inventions, and nearly every modern turbine principle and some others will be found exemplified. It is assumed that these ideas were abandoned because of the then apparently greater promise of the reciprocating engine and the undeveloped stage of machine shop practice which rendered production of efficiently shaped blades practically impossible.

The steam turbine is generally regarded as of European origin, the reduction to useful practice having been carried out by Messrs. Parsons and DeLaval, and it is not generally known that steam turbines were commercially built in Syracuse, New York, as early as 1833. Several of these were sold and employed for driving saw mills, and were of the kind which might be described as of the "Hero" type, steam being admitted through the shaft and issuing tangentially from two radial arms. One user of these, Mr. N. Felt, of Cicero, New York, reported in 1835 that the turbine driving his saw mill used two-thirds the fuel of the reciprocator it replaced.

It is reported that in 1836 one of these was placed upon a locomotive near Newark, New Jersey. The turbine had an arm tip speed of 14.25 miles a minute. Its life was ended in a ditch. It is, however, interesting to record that Parsons built a precisely similar machine about 1890, comprising a single "Hero" element. Its capacity approximated 20 horsepower, and with 100 pounds pressure and 26 inches vacuum, had a steam consumption of 40 pounds per horsepower hour. His attempts to improve performance by compounding were unsuccessful because of the friction of the arms in the more dense fluid.

Charles A. Parsons

No historical review of the development of steam turbines would be complete without tribute to the work of Sir Charles A. Parsons, who, in spite of the many difficulties to be overcome, had the courage of his convictions and expended a large personal fortune in this work. He commenced work in 1884 by determining whether bodies could be operated at eighteen or twenty thousand revolutions per minute, and then proceed to the building of a small turbine. Sir Charles at the outset thoroughly realized that the sphere of the steam turbine was in large sizes rather than small, but he had associated himself with a firm of engineers whose principal business was the equipping of ships with donkey boilers, winches, windlasses, etc., so it was natural that his activities were confined to the building of lighting sets for shipboard use. These sets were of small capacity, running at from fourteen thousand to eighteen thousand revolutions per minute, driving direct-current generators. The generators, while highly unsatisfactory from the standpoint of a modern direct-current machine, were remarkably ingenious in their design. It was not until he dissolved partnership with the above mentioned firm and established his own engineering works that he was enabled to build steam turbines and apply them to what he believed to be their proper sphere, viz., central station work. He applied them to the earliest central stations, viz., Newcastle, Cambridge, and Scarboro, in England, in 1889, a 75-kilowatt machine being furnished to the former city. Of course, early progress was retarded by the small demand for high-speed machinery. Practically their only application was for driving dynamos which were then built only in small sizes.

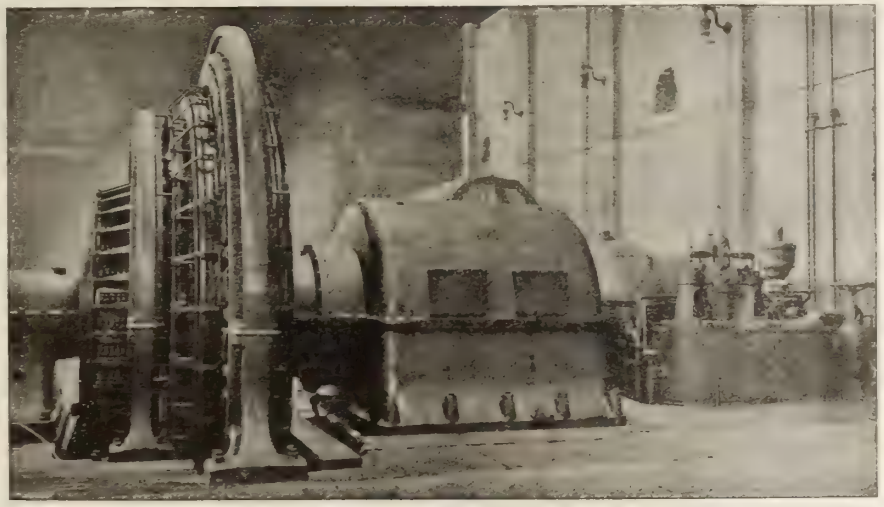

FIG. 1.—GEARED TURBINE DRIVING LARGE D. C. GENERATOR

During the period from 1884 to 1889 about 300 turbines were built ranging up to 75 kilowatts. In 1894 a number of 350 to 500-kilowatt non-condensing turbines were built for driving 50-cycle generators at 3,000 r.p.m. These were furnished to various electric lighting companies in London and displaced both Willans and Westinghouse single-acting engines, as the company operating them had received an injunction on account of the vibration being a nuisance to the

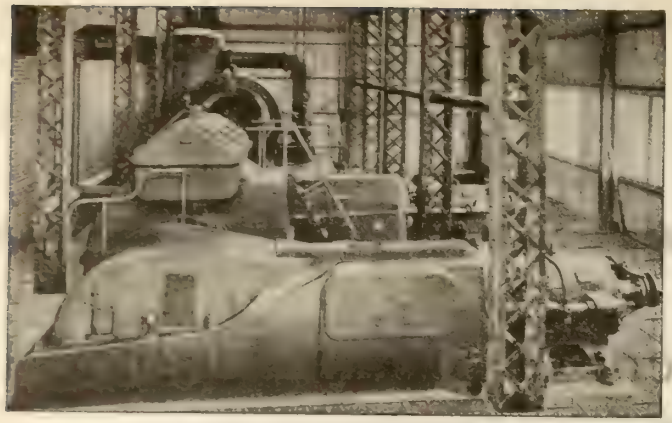

FIG. 2.—ANOTHER GEARED TURBINE APPLICATION

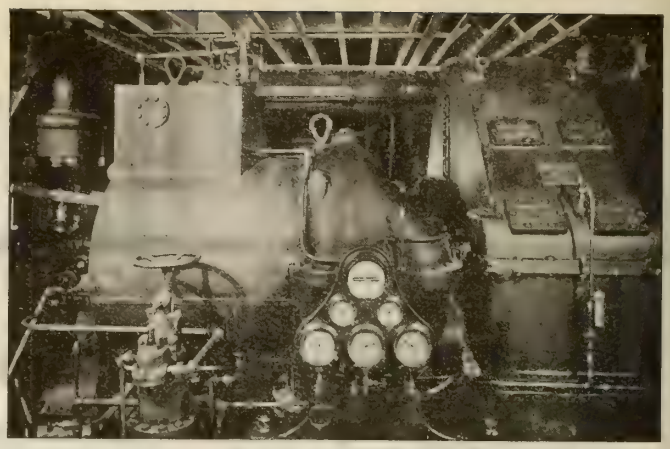

FIG. 3.—GEARED TURBINE

community, which was withdrawn with the installaton of these turbnes.

Sir Charles Parsons has been unrelaxing in his energy in the development of steam turbines, his efforts culminating finally in the construction of enormous turbines for direct connection to the propellers of express steamers, the engineering difficulties to be overcome in their construction being of a far higher order than that required for the most successful high-speed turbine for land service.

American Development

In 1896, the steam turbine as a practical machine was almost unknown in the United States. A foreign built DeLaval turbine of 300-kilowatt capacity had been furnished to the Edison Company of New York. A few Dow turbines of small capacity had been built, and while exceedingly ingenious in their character, they did not have much commercial application except for use in speeding up the flywheels of Howell torpedoes for the United States Navy.

At this time Mr. George Westinghouse, realizing with his characteristic foresight the possibilities of the turbine, secured for the Westinghouse Machine Company the rights to manufacture them under a license from Sir Charles A. Parsons. In 1896 a 120-kilowatt turbine was built in Pittsburgh of condensing design and drove a direct-curren generator at 5,000 r.p.m. This turbine had a water rate of 25.6 pounds per kilowatt-hour operating with 160 pounds steam pressure and 27.1 inches vacuum. The turbine was regarded as entirely satisfactory, but it need hardly be said that the generator did not come up to standards of direct-current apparatus, even of that day. In the succeeding years this company was substantially alone in the turbine field; gas engines and large Corliss engines occupied most of the activities of the company, so that until 1899 turbine development, except for some experimental machines, was practically at a standstill.

During the year 1899, the powerhouse of the Westinghouse Air Brake Company, Wilmerding, Pa., was equipped with three 400-kilowatt turbines, which was the first serious turbine installation carried out in this country. The performance of these machines with 150 pounds steam pressure, 100 degrees F. superheat, and 28 inches of vacuum was as follows:

Brake Horsepower. Load in	Brake Horsepower Hour. Pounds Steam Per
264	14.48
445	12.87
593	12.05
759	12.06

A quite historic turbine installation was made in 1900 at the plant of the Hartford Electric Light Company, Hartford, Conn., which was of 2,000-kilowatt capacity, running at 1200 r.p.m. This turbine was at least twice as large as any turbine that had ever been built, and caused much comment at that time. The whole of the expansion was carried out in a single cylinder. European turbine builders, commenting on this, regarded it as a courageous thing to attempt to build such a large turbine structure in one single cylinder, and here came about a crossing of ideas, which is not infrequent in engineering process; viz., two groups of engineers each abandoning their own line of progress and adopting that of the other.

Tandem Compound Turbine

At this same time, viz., 1900, Sir Charles Parsons constructed the historic Elberfeld machine wherein the expansion of steam was carried out in two separate turbine cylinders coupled to each other tandem fashion. This machine, operating with 144 pounds absolute steam pressure, 26 degrees F. superheat, and 28.2 inches of vacuum, gave a steam consumption of 19.0 pounds per kilowatt-hour at 1250-kilowatt load.

Sir Charles Parsons and also Brown Boveri of Basle, who had by that time become a licensee of Parsons, encouraged by the success of the American Hartford machine, proceeded to build large

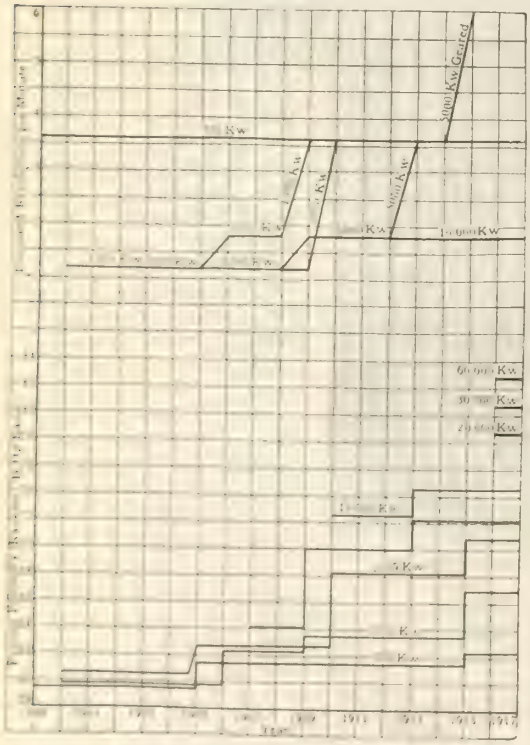

FIG. 4.—PROGRESS IN 25-CYCLE TURBINE DESIGN

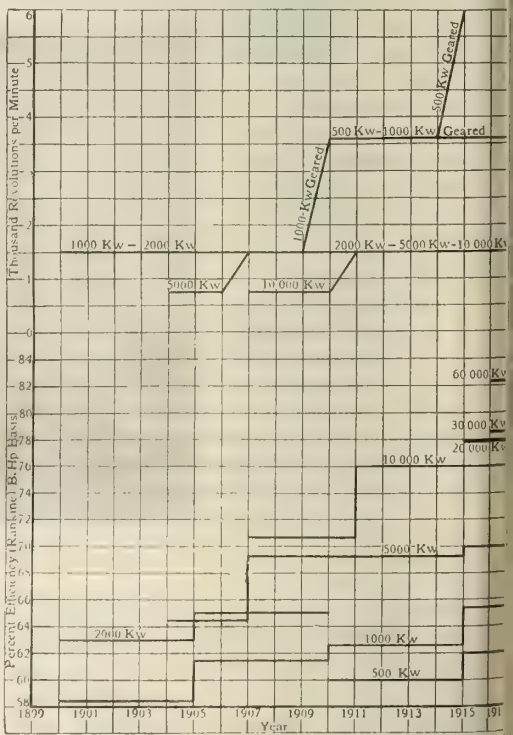

FIG. 5.—PROGRESS IN 60-CYCLE TURBINE DESIGN.

size turbines in single cylinder, while we in America, being impressed by the reliability to be obtained from dividing the steam cycle of the turbine into two separate elements, proceedd to build several machines of from 1,000 to 2,000 kilowatt-capacity in two cylinders; these being constructed in 1903. Plainly two cylinder machines of such small capacities were expensive, but it is interesting to point out a reversion to this type, by the Westinghouse Company, in the last two years. The Hartford machine above referred to caused sufficient interest that the General Electric Company saw their way to enter the turbine field and shortly thereafter commenced the construction of 5 000-kilowatt units for the Commonwealth Edison Company of Chicago.

Referring again to the two-cylinder tandem turbines built in 1903; one advantage of the design was expected to accrue from the use of a reheating receiver between the two cylinders. Tests, however, showed clearly that the gain due to this did not warrant the expense when high pressure steam was used for reheating. But the prophecy is ventured that there will be a reversion to intermediate reheating by means of separately fired superheaters for large machines in the near future.

Growth in Capacity

Th rapid strides made in central station practice in this country have brought about developments of turbines for land purposes in sizes that have gone beyond any Eupropean practice, and very remarkable steam engine performances have been obtained by the principal manufacturers. There is an impression that this development has, in this country, within the era say from 1900, grown from a very poor and uneconomical machine. This, however, is not true of the Westinghouse Company for it is seen from the steam consumption of the earliest machines quoted and in what follows that they do not compare very unfavorably with what can be done to-day with similar speds and capacities. Unquestionably improvements have been made in producing less expensive and more reliable detail design. Improvements in economy, however, have been due to increased speeds for a given capacity rather than to any material change of thought or principle as regards turbine systems. Very material advances have been made in the development of the high-speed alternating current generators which have permitted turbines to be designed more appropriately for the volumes of steam involved. To-day, 5,000-kilowatt 60-cycle machines have been built for operation at 3600 r.p.m., while in the year 1900 electrical engineers looked askance at such speeds even for 500-kilowatt units and regarded 1800 r.p.m. as the more desirable speed for this capacity and frequency. Improvements in condensing apparatus have also contributed to the development of the turbine, bringing ordinary available vacua from 26 inches to 29 inches, this improvement having been brough about by the demands of the turbine builder, which were largely responded to by manufacturers of the more modern systems of condensers apparatus.

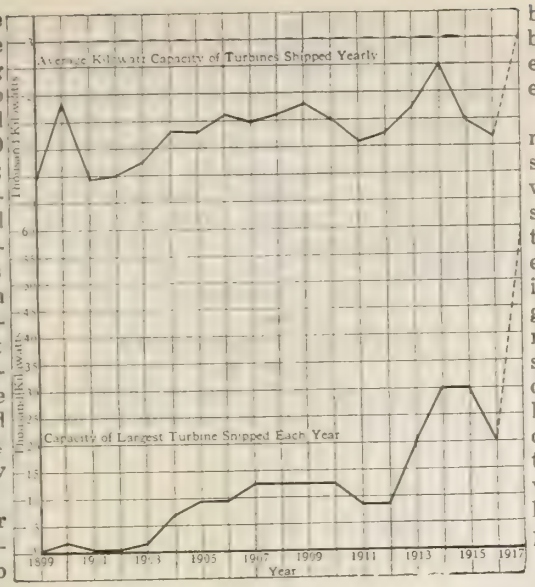

FIG. 6—GROWTH IN SIZE OF INDIVIDUAL UNITS

To-day it may be said that the maximum capacities of generators at given speeds are as great as the capacities for which the turbine can be conveniently designed. In other words, the turbine ceases to be a machine of too high speed for general application. It may be designed for its best speed and direct connected to the generator in the case of alternating-current machinery for all but the smaller sizes below 500 kilowatts. It may be still operated at its most economical speed and by the intervention of toothed gearing be connected to direct-current generators or to other apparatus for any other purpose whatsoever, including direct mill drive, large reciprocating pumps and the propulsion of ships.

Reduction Gears

The principal field for the steam turbine in the past has been driving a-c generators; and as there are, broadly speaking, but two frequences in conventional use in this country, 25 and 60 cycles, the speeds available were limited. Because of the difficulties of electrical transmission there has not been much demand for direct-current generators of large size. Further, because of the difficulty of designing direct-current generators for high speeds, the number of direct-current turbine installations is comparatively small. In the installations of direct-connected turbines and direct-current generators which were made, the speeds selected were too high for successful operation of the generators and too low for the economical operation of the turbines. Within the last eight years, however, reduction gears have been developed which remove this objection; so that to-day first-class designs of direct-current generators may be driven by turbines as successfully as can alternating-current units. A number of such geared outfits have been installed, giving entire satisfaction, the speeds being as follows:

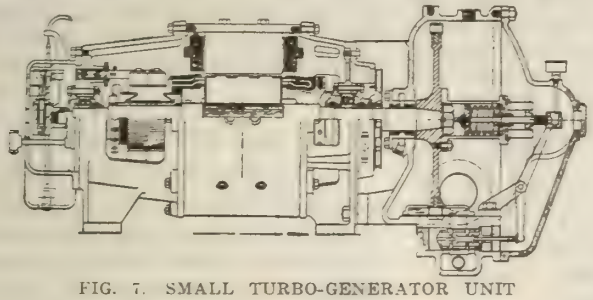

FIG. 7. SMALL TURBO-GENERATOR UNIT

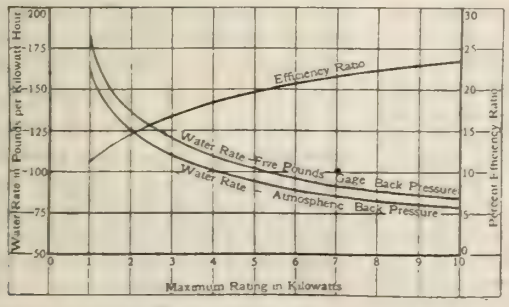

Efficiency Ratio
Water Rate—Five Pounds Gage Back Pressure
Water Rate—Atmospheric Back Pressure
Water Rate in Pounds per Kilowatt Hour
Percent Efficiency Ratio
Maximum Rating in Kilowatts

FIG. 9.—PERFORMANCE OF SMALL TURBINE

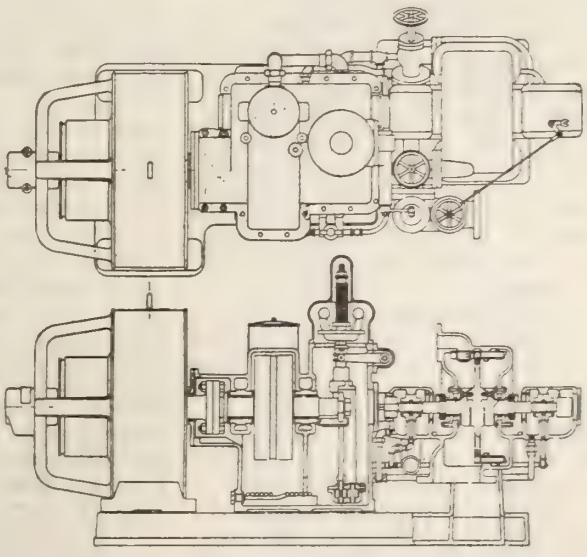

FIG. 8.—SMALL GEARED UNIT

Capacity Kw.	Turbine Speed R.P.M.	Generator Speed R.P.M.
150	6,000	900
300	6,000	900
500	5,000	720
1,000	3,600	514
1,500	3,600	360
3,750	1,800	180

The generator speeds given above are standard for motor-generator sets. Examples of important geared installations for purposes ordinarily considered outside the field of the steam turbine, is given in Figs. 1 to 3.

The improvements which have been made in turbine performance since 1899 are shown by Figs. 4 and 5, for 25 and 60-cycles respectively. These curves show how speeds have been changed with the progress of time, each change of speed having been more productive of improved results and improvements in what are essentially turbine principles. The comparisons have been made on the basis of the efficiency ratio rather than steam consumption, because to make a comparison with the latter the results would have to be reduced to a common operating condition, which would be improper. Should a high operating condition be selected it would not be fair to some of the older machines, which were hardly adapted to operate with high superheats and vacua, and the later machines would be at a disadvantage if their results were reduced to a low operating condition. The effect of the condenser on turbine development has been previously referred to. The improvement of condenser performance is directly attributable to the demands of the turbine. Early turbines had their low pressure elements designed to be suitable for vacua not much over 26 inches. All turbines nowadays are designed to expand steam at their point of best steam consumption to 29 inches vacuum.

Fig. 6 is of passing interest, showing the increase in the capacity of single units as built from year to year. The average capacity of turbines is also shown; it has not, however, been continuously an upgoing scale on account of the growth of business in single wheel impulse turbines of small capacity. In 1909 was commenced the development of small, single disc, non-condensing turbines of the re-entry type, intended primarily for the operation of condenser auxiliaries. Their general performance was so encouraging that in the course of time a line of excellent small machines suitable for electric generator drives, and also adaptable for driving any other kind of machinery have been developed. The smaller ones, up to 15 kilowatts, are direct-connected; above that they are geared. The general schemes of design are shown respectively in Figs. 7 and 8, and their performance in Figs. 9 and 10. The r.p.m. shown on the curves represent the speeds of the turbine shaft; the gear ratio being arranged to suit the driven machine.

FIG. 10—PERFORMANCE OF A GEARED UNIT

UNUSUAL LUBRICANTS

By M. M.

The problem of lubrication is by no means simple and its complexity has been pointed out on many occasions. Lubrication is conditioned by many circumstances.

A spindle from the machine and likewise the bearing in which it is carried have surfaces which consist of circumferential grooves. These are minute, but until the surface more nearly approaches a perfect cylinder, a new bearing requires unusual care until run in, otherwise until the hills have been abraided to the level of the valleys. It is by no means well known that longitudinal drawfiling with a dead smooth file has, before to-day, restored running conditions in a bearing which would not behave. For large spindles such treatment is beneficial before erection and is seriously recommended. Since it will restore a bearing which persistently runs warm to a sense of due behaviour, it is worth more general adoption.

There are instances where a big job must be kept running at all costs with a hot bearing, and playing a hose on the same may dissipate the heat, but does not remove the conditions; leading as it does to very rapid wear.

There are a few simple prescriptions all of them tried and found successful, which have restored a hot bearing to good running conditions, when shutting down was impossible. Heavy doses of castor oil and minute alterations or injections of distilled water, to induce saponification, is one remedy. Graphite and lubricating oil is another. The worst cases are those in which a steel spindle runs in gun-metal, and there is no remedy to compare with flour of sulphur mired with lubricating oil; it acts like a charm in most instances, and is strongly advised.

Cast iron sliding on cast iron gives in time a surface skin whose co-officient of friction is very small, and such skin is not easily broken. When this surface is abraided, the conditions are rather startling, for actual red hot sparks commence to fly in a very short time, and lubricating oil simply burns to a carbon deposit, and has no effect whatever. Putty white lead, mixed with lubricating oil, has been successfully used to cure even these conditions. The most unusual lubricant which came under personal notice and experience was used in the thrust bearing of a steamer, and had been utilized there for many years. As is well known, the type of bearing has a large enclosed volume which can serve as a bath. This was filled to axis of shaft with a solution of soft soap in distilled water, about 1 cwt. of soft soap sufficing for six month's use. The entire contents were occasionally changed, and a daily feed of about ½ pint of strong solution added. The bearing never gave trouble unless a new greaser started to oil it, when its temperature increased in direct ratio to the amount of oil.

When a bearing gets hot, the metals are in intimate contact, and the normal film is broken down. The remedies noticed restore conditions by the interposition of a more durable film between the surfaces. They give an artificial skin to the bruised surfaces, and allow gradual restoration of its condition.

Unlike the nigger doctor, who gave rosin and alum for a broken limb—the last to draw the bones together, and the first to stick them—the remedies, although perhaps not scientific, are successful. A word of caution is perhaps advisable—don't follow Mark Twain in his cure for a cold, and mix the remedies—give one a chance before trying another.

Finally, the remedies here noticed are known to, and practised by, marine engineers, and they have before to-day, kept the job running when a shut down on a lee shore would have meant disaster. This last for the sceptic who may be inclined to doubt their efficacy.

GAS RIVET HEATERS

At the Bethlehem Shipbuilding Corporation's Alameda Works, U.S.A., gas is henceforth to be used exclusively for rivet heating, plate-bending, and general fabricating heating purposes. This is a radical departure from the shipbuilding methods that have been in use for years, whereby it was thought that only coke could be used—even oil was considered an innovation. Good work by a riveting crew depends to a great extent on properly heated rivets. With a continuous and uniform gas forge the heater man can give his undivided attention to regulating the forge so that there will be no burned or overheated rivets, irrespective of the speed at which the crew works. This tends towards regularity, with properly upset and tight, full-headed rivets as a result. The cooling contraction is likewise more uniform, and caulking is reduced to a minimum.—"Chemical and Metallurgical Engineering."

Power Plant Management; Hand Firing

Methods of Hand-Firing—Standard Practice—Proper Combustion Conditions—Thickness of Fire—Minimization of Smoke

By ROBERT JUNE

A MINER will produce, on the average, 10 tons of coal per day, 22 days per month. This is at the rate of 220 tons monthly, or 2,640 tons yearly.

Our present annual consumption of hituminous coal for industrial purposes is fully 250,000,000 tons. Of this amount, we are wasting to-day, in a preventable manner, anywhere from 10 to 25 per cent. Conditions are improving. Let us give ourselves the benefit of the doubt by conceding a 10 per cent. waste. That is 25,000,000 tons.

Twenty-five million! The figures slip glibly enough from our tongues, for are we not all infected with cypherosis, and used to dealing in big sums? But if we would realize the magnitude of the loss we must resolve it into concrete terms which can be visualized. 25,000,000 tons is 500,000 carloads—enough to make a train 3,840 miles from engine to caboose, long enough to reach from New York to our battle front in France, where its energy belongs.

This train represents the continuous labor for a year, of 85,000 men. We would have four new divisions of over 20,000 men to send against the Kaiser if we would eliminate the waste. Were we to utilize the 25,000,000 tons instead of wasting it, we would have the heat and power required to produce a combined fleet of 50,000 motor trucks, 50,000 tanks, 50,000 airplanes, 2,500 submarine chasers, and 250 merchant vessels.

Of the various sources of coal waste in the power plant, improper firing is among the most important. Also, given a fair measure of intelligence, good intention and determination to improve operation on the part of the boiler-room crew, improper firing may be easily bettered.

There are two general methods of hand-firing; first, the spreading method, second, the coking method.

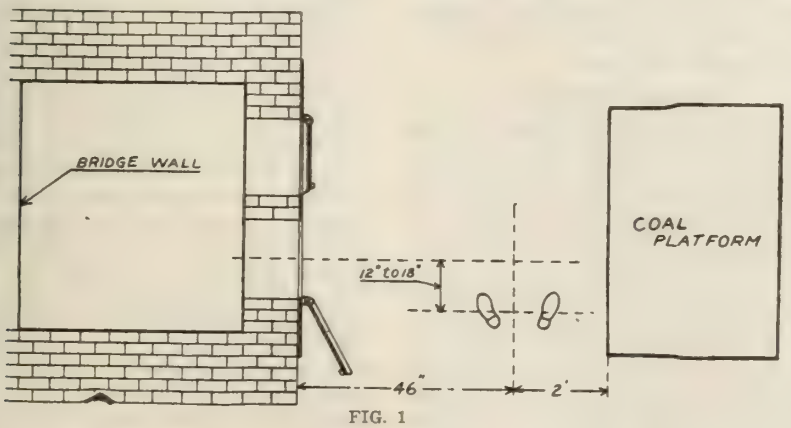

FIG. 1

In the spreading method a small amount of coal is fired at one time, and spread evenly over the fuel bed, front to rear. In order that the entire fire may not be blanketed with green coal, the surface of the bed is divided into sections which are fired alternately. Thus on a furnace with three firing doors the rear half of the grate is fired through doors 1 and 3, and the forward half through door 2 at the same time. At the next firing the arrangement is reversed, and the forward half of the grate fired through doors 1 and 3, and the rear through door 2.

In the coking method, fresh coal is fired at considerable depths at the front of the grates, and when nearly or wholly coked is pushed to the back of the furnace. The object is to maintain a bed of incandescent carbon at the rear of the grate, in passing over which the volatile from the green coal at the front will be burned. This method is particularly adapted to furnaces wherein gases pass horizontally over the fire.

Before each firing the coked fuel is pushed back, leaving about one-third of the grate bare and all of the green fuel on the bare grate. The fire door is cracked slightly to admit air for the volatile gases.

Of the two methods, it may be said that modern practice leans more and more to the spreading method. This is because of its evident tendency to produce higher efficiency, higher CO_2, lower flue gas temperature, and more uniform steam generation—results attributable to greater constancy in furnace temperatures.

On the other hand the coking method produces less clinker since the levelling of the fire at the firing period shakes more ash through the grates. The longer firing period produces a general lowering in CO_2, and there is a tendency to admit excess air through the thin spots. The coking method cannot be used successfully with a fluctuating load, as holes which cannot be seen develop in the rear of the fuel bed.

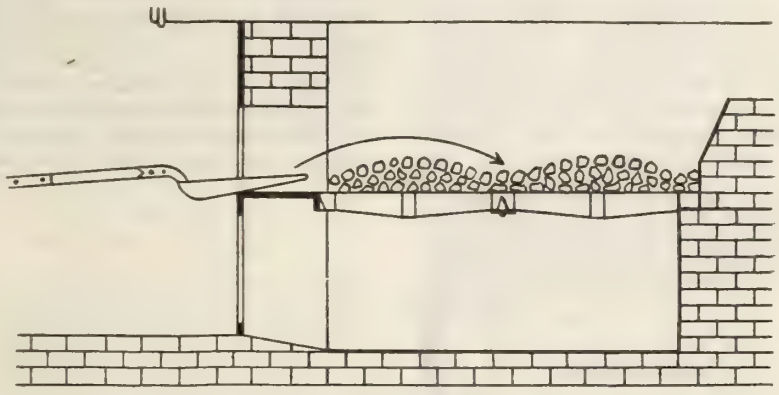

FIG. 2

Standard Practice for Hand-Firing

The position of the fireman and the location of the coal pile have a great deal more to do with securing good results in hand-firing than is generally realized.

The fireman must take a proper position so that he can see the thin spots and can throw the coal onto them with the least effort. He should stand 4½ to 5 feet in front of the furnace, and 12 to 18 inches to the left of the center of the door, see Fig. I. He should then be about two feet from the coal, which is 6 or 7 feet from the furnace front and should preferably be on a car, or an elevation, knee-high from the floor.

The scoop should travel in a nearly straight line. At the end of the throw the scoop should suddenly be stopped by laying it on the bottom edge of the door frame. The coal then flies off and is scattered over the proper spot. By thus stopping the scoop the fireman saves effort and locates the coal better. If he pushes the scoop way into the furnace he has to jerk it back to get the coal off. See Fig. II.

Hand-firing is hard work, and requires considerable judgment and skill. There should be sufficient firing space for handling the shovels and tools.

If the coal is closer than 6 or 7 feet the fireman is crowded and will stand

away to one side of the door to avoid the intense heat. He cannot see the fire and throws the coal in by guess. His scoop travels in the arc of a circle, scattering coal on the floor and dumping it in a heap directly inside of the door, see Fig. III. This results in an uneven fire, low efficiency, and requires raking of the coal on to the back of the fire.

Provide a smooth firing floor, or a smooth bottom to the coal car, so that the shovel does not hit bumps or rivets. Such obstructions delay the firing operation, keeping the door open longer than necessary and admitting an excess of air.

Benefits of Rapid Combustion

Coal should be burned rapidly and at high temperatures in order to secure the best available economy. Fire small quantities of coal at short intervals so that thin places do not burn through and admit large excess of air. The quantity depends upon the grate size and the drafts. With a draft of one inch in the uptake, 2 to 2½ pounds per square foot of grate is a good average. Thus, on a grate 6 by 8 feet, 100 to 125 pounds of coal, or about 6 to 9 shovelfuls, would be the quantity for one firing. The intervals should be about five minutes. For a higher draft the periods could be three minutes; with a weaker draft they could be lengthened to eight minutes, but under ordinary circumstances should never be more than ten minutes. This method makes the coal supply more nearly proportional to the air supply, which in most hand-fired plants is nearly constant.

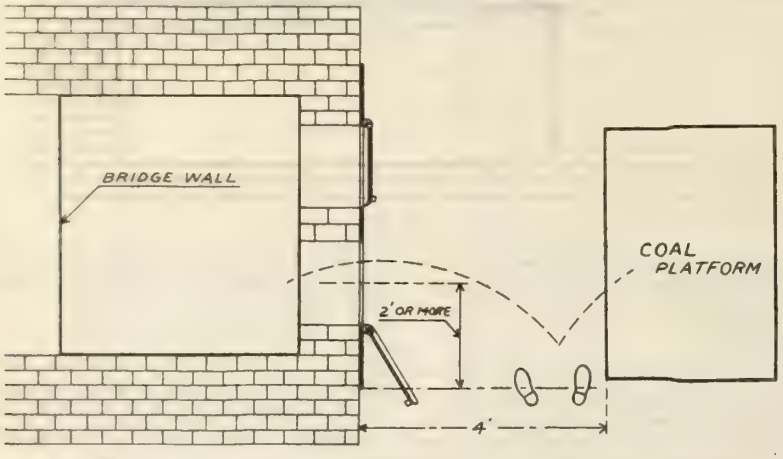

FIG. 8

The following are reasons for light and frequent firing: When fresh coal is fired the volatile matter is immediately distilled. The process is nearly completed in 2 to 5 minutes, therefore immediately after firing large quantities of air should be admitted over the fire. After 2 to 5 minutes it should be cut down. Such regulation is practically impossible. As the air supply is practically constant, immediately after firing it becomes insufficient, and incomplete combustion results. After most of the volatile matter has been driven off the air is in excess. The two losses are much less when small amounts are fired at frequent intervals. Automatic air control devices can be purchased, but even with them frequent and light firing is best Frequent firing alleviates the tendency to form a crust on the top of the fuel bed.

Cover Up the Thin Spots

A skillful fireman can, at a glance, estimate the amount of coal required at a given spot. Almost unconsciously he picks the right amount and selects the right mixture of fine and coarse coal. If the coal is burned way down he selects coarse coal to avoid its sifting through the grate. This also permits of the building up of the level on the spot more quickly, as the coal does not tend to fuse so much as slack. Thin and thick spots will occur, even with most careful firing. In places where the air flows freely the coal burns faster, forming a thin spot. The cause of the variation in air flow may be the difference in the size of the coal, the accumulation of clinker or the fusing of coal into a hard crust. Before firing fresh coal the fireman should note the thin places. They have bright, hot flames, while high spots have smoky flames, or none at all. Cover the holes, if burned through, with incandescent coal before firing. Place the coal on the thin spots in thin layers. If deep hollows are filled at once fresh coal may fuse and choke off the air, forming a new high spot. If high spots are missed for one or two firings they will burn down to normal. If the high spot is due to clinker, the clinker must be removed.

Thickness of Fire

With one inch draft available at the breeching, firing run of mine coal, a 4 to 8 inch fuel bed is best; the coarser the coal the thicker the bed. A thick bed offers more resistance than a thin one, therefore with the same available draft there is less air passed through a thick fuel bed, which means a lower rate of combustion and lower capacity. If difficulty is experienced in maintaining steam pressure with a thick fuel bed, it may be possible to overcome the difficulty by carrying a thinner bed. The objection to a thin fuel bed is that too much air flows through without uniting with carbon, but a thin fuel bed does not pass oxygen through unburned unless there are holes in it. Evidence shows that from a fuel bed 3 to 4 inches thick the gases rising from the surface average less than 2 per cent. oxygen, and about 25 per cent. combustible gas. As a result considerable air must be admitted through the fire-doors and other openings to burn the combustible gases. A thick fuel bed does not necessarily decrease the free oxygen in the flue gas but may actually increase it. Thickening the fuel bed increases the resistance to the passage of air. As the fuel bed is thickened less air passes through it, and less combustible gas rises from its surface.

The higher draft, however, brings in more air over the fuel bed, resulting in a greater amount of free oxygen in the flue gases.

The Smoke Problem

Hand-fired furnaces, as a rule, are most obstinate smoke producers. Although they can be operated efficiently without the production of objectionable smoke the result depends more upon the fireman than upon the design of the furnace. The chief difficulty with hand-fired furnaces lies in the intermittent nature of the firing. When a fresh charge of coal is fed into the furnace an enormous volume of volatile matter is evolved. For complete combustion a corresponding amount of air must be supplied and intimately mixed with the volatile gases before contact is made with the comparatively cool heating surface. In the average hand-fired furnace the combustion chamber is so small and the heating surface is so close to the grate that the partly burned gases strike the heating surface before oxidization is complete and combustion is hindered or even completely arrested. The most economical and smokeless hand-fired plants are those that approach the continuous feed of the mechanical stoker.

Minimizing Smoke in Cleaning Fires

Two methods of cleaning fires in hand-fired furnaces are in general vogue. In the side method, one side of the fire is cleaned at a time. In the front to rear method the burning coal is pushed with the hoe against the bridge wall, the clinker from the front half of the furnace is loosened and pulled out and the burning coal is spread over the bare grates, the process then being reversed for the rear half of the furnace. For smokeless operation the side method is preferable and should be carried out as follows:

Build up the fire on one side and let the other side burn down. Just before cleaning, "wing" over the live coal from the burned-out side and pull out the clinker and ash, cleaning the grates thoroughly. Cover the clean grates with green coal and push over live coal from the other side. When the cleaned side has become thoroughly ignited and the volatile matter has passed off, throw in coal to fill the spots not covered and pull the clinker and ash out of the other side. Cover the grates with green coal as before, winging over live coals from the opposite side. Keep the panels wide open and allow the fresh coal to ignite thoroughly. Never allow the fire to burn

low before cleaning, if carrying a heavy load as there is a possibility of losing the steam pressure.

The following rules represent the best standard practice in eliminating smoke in banking fires: Throw 15 or 20 scoops of coal on each side. Open the panel doors slightly, close the ashpit doors and partially close the damper. To break up the bank, level the fire with the panel doors open and start firing by the usual method, making sure the damper is wide open.

Keep the fire bright by the spreading method, using the panel doors and steam jets, and regulate the steam pressure with the ashpit doors. This insures a temperature in the furnace high enough to maintain the brickwork at the igniting points of the coal and promotes combustion of the volatile matter. At the same time it keeps down the distillation of the volatile matter to a low rate, and by having the damper open and the panels cracked, the circulation of the gases is not retarded. Do not try to regulate the steam pressure by the damper or smoke will be produced.

The method just described is contrary to the general rules for firing, but its philosophy is explained in the following manner: If a shovelful of coal is thrown on a bright fire by the spreading method, every particle of that coal is immediately subjected to the intense heat of the fire and the volatile matter is rapidly driven off. If this is followed by more coal, the result is a volume of volatile matter which is beyond the capacity of the furnace to handle without dense smoke.

If, on the other hand, the fuel is fired in a lump from the shovel without spreading there is a considerable quantity of the coal which does not immediately become subjected to the high temperature. The coal on the outside of the pile gives up its volatile and the coal within is not affected until the volatile matter has been distilled from the outside lumps. Furthermore, the volatile matter from the inner portions of the pile must pass outward through the incandescent outer layer of fuel, much in the same way as in the underfed stoker. In this way the production of smoke can be retarded, and the more coal thrown on the fire at once, the less smoke. Two shovelfuls of coal fired by the spreading method on a clean, bright fire, will make more smoke than ten shovelfuls fired by the lump method. In practice it will be necessary to determine just how much coal should be fired at once, but six or seven shovelfuls on a side with the draft operated according to the method ordinarily used will be found to be about right.

When a battery of boilers is to be fired the fires should be fed by the spreading method, as before, passing from one boiler to another until they are all charged and then repeating on the other side of the furnace. It should be determined by experiment, however, just how many furnaces can be fired consecutively without producing dense smoke, and after this has once been made known, the fireman should adhere strictly to the rules laid down in this regard.

CASTOR OIL RANKS TOP OF LIST AS THE BEST KNOWN LUBRICANT

PERHAPS your earliest recollection of castor oil was of having a fond parent hold your stubby nose while the stuff stuck to the roof of your mouth, your windpipe, and all your tasting and sampling organism. But apart from that you never paid much attention to it. Just now it is pulling down fancy prices The price of castor beans advanced in a few months from about $1.25 a bushel to $3.50, which was the price the government guaranteed those who would produce the necessary beans. This price has been found too low, and so the government has offered the large grower or contractor $4.50 a bushel for all the castor beans he can deliver. It is certain that the demand will continue to grow as more airplanes are built, and that the moderate and the chronic drinker of castor oil will continue to pay war or government vendor's prices for his tipple until peace has been declared.

The Perfect Lubricant

The lubricating value of castor oil was not left for this war to disclose, but it was not until the war was well under way that experts came to appreciate just what a wonderful lubricant it is. It is agreed that for many purposes it is the very best in the world, and this is especially true with regard to airplanes. The propellers of these craft are turned at a far greater number of revolutions a minute than the engine of an automobile, and at every impulse stroke there is developed within the cylinder of the engine inflamed gas of very high temperature. This intense heat will attack and consume most mineral oil lubricants, thus seriously impairing the engine. If the high temperature of combustion burns up the lubricating oil or thins it out so that it no longer furnishes the required anti-frictional film between contiguous metal surfaces, the pistons become too hot, expand, jam, and the machine is stalled. The consequences of a stalled engine in an airplane flying over the enemy lines, or perhaps engaged in battle need not be emphasized.

Indifferent to Temperature

Tests has shown that castor oil will not be burned up or thinned out by any heat that an airplane engine will develop. It will maintain its body at all times and flow freely through the distributing system whatever the temperature. Many other lubricants are affected by the cold, and it often happens that while the ground temperature may be 80 degrees or more, the air will be below freezing point at an altitude reached in a few minutes by an airman. Castor oil is a perfect lubricant in these circumstances, and wide differences in temperature appear to make little or no impression upon it. These facts were proved by exhaustive tests made in the United States to discover the perfect airplane lubricant, and naturally enough when it was found that castor oil was the best and that anything else was at best a makeshift, likely to fail in some important particular in some circumstances, the War Department set out to buy all the castor oil in the country.

Does Best in Hot Climates

When the available supply was secured, it devolved upon the Agricultural Department to induce growers to raise more castor oil beans, and the result has been satisfactory, although there continues to be a shortage. The beans may be grown in practically all parts of Canada and the United States, but they thrive best in semi-tropical conditions. In Florida, Texas and Oklahoma they have been extensively planted, yielding there from thirty to forty bushels an acre, while in the Middle West the yield is about one-half as great. But the United States, judging from the land devoted to the cultivation of the bean this year and likely to be cultivated next year, will hardly supply one-fifth of the demand of the American Department of War, let alone supplying any of the allies, and as in the past the chief reliance will have to be placed upon the imported article. In the tropics the bean flourishes like a weed. Where cultivated it begins to produce in from five to six months. and from that time on is a ceaselessly yielding perennial, and the seeds can be gathered month in and month out the whole year round. The war demand has resulted in hundreds of thousands of additional acres being planted with castor beans in India. Siam, China, and Central and South America.

Has Many Uses

The castor oil bean has many other uses beside that of a lubricant, medicinal or mechanical. In India it is very largely used for illuminating purposes. The oil burns very slowly and gives a light of notable brilliancy. In the United States, according to the "New York Sun," it is indispensable in the manufacture of imitation leather and rubber. Some kinds of soap could not be produced without castor oil, and from it there is also manufactured what is known as sulphonated oil or Turkey red oil, which is used as a softener or filler for cotton goods. It also enters into the makeup of the tracer bullet. In view of the foregoing facts there appears to be more than a germ of truth in the battle cry, "Castor oil will win the war!"

STARTLING WASTE OF OIL

Startling waste is shown by experts of the Bureau of Mines, Department of the Interior, who have been co-operating with the Fuel Administration in a general survey of the use of fuel oil for power purposes in the United States. They find that last year 160.000,000 barrels of fuel oil were used and that 40.000.000 barrels, or one-fourth of the entire amount, was wasted and might have been saved by proper firing.

The Calculation of Alternating Current Circuits

Simple Rules For Conditions Usually Met With in Practice— Their Application to Actual Problems and Tables of Constants For Simplification of Work

By GORDON KRIBS, Assistant Engineer Hydro-Electric Power Commission of Ontario

THE calculation of the size of wire necessary, under given conditions, for an A. C. circuit is usually considered by the average superintendent as rather too complicated to attempt, and the usual practice seems to be to guess at the size of wire necessary, calculate it on the basis of a direct current circuit and add something for good luck, or use the size of wire which has the required current-carrying capacity.

The writer is not aware that any very simple method of calculating alternating current circuits has been published and so the accompanying tables have been devised in the hope that they may fill a long-felt want and provide those interested with a simple means of calculating alternating current circuits accurately with minimum expenditure of time and labor.

The following explanation applies to the attached tables which have been calculated for both 25 and 60 cycles:—

Three power-factors have been assumed as representative of the various types of load, viz.:—

95% for lighting loads.
80% for a combined lighting and power load.
65% for a strictly power load.

Single-Phase Circuits

In order to calculate the size of wire necessary for a single-phase circuit, **multiply the load in kilowatts by the distance to be transmitted in feet and divide by the regulation or per cent. voltage drop desired.** This will give the constant K for this particular circuit

$$K = \frac{\text{Distance in feet} \times \text{K.W.}}{\%\ \text{Regulation}} \qquad (1)$$

Now look up, in the table calculated, for conditions corresponding to those of the circuit in question, the number most closely corresponding to this constant, and, opposite this number, find the size of wire necessary in order to obtain the desired drop under the given conditions.

Example.—It is required to transmit 25 K.W. at 600 volts, 60 cycles, 80% P.F., a distance of 1,000 feet, with an allowable line-drop of 5%. What is the proper size wire to use?

$$\text{Constant} = \frac{1000 \times 25}{5} = 5{,}000$$

Now in proper table, under 80% P.F., find the number most closely corresponding to 5,000. This is found to be 5,254. Opposite this number will be found No. 4 copper or No. 2 aluminum, as the proper size wire to use.

Conversely, by re-arranging formula (1), we have

$$\%\ \text{Regulation} = \frac{\text{Distance feet} \times \text{K.W.}}{K} \qquad (2)$$

Or, in other words, to find the regulation under given set of conditions for a given size wire, multiply the load in K.W. by the distance in feet and divide by the constant found in the tables for that size wire under the given conditions.

For three-wire circuits, use the voltage between the two outside wires, finding the proper size for these wires. For the neutral, it is considered good practice to use a wire one-half the cross-sectional area of the two outside wires.

Two-Phase Circuits

Since two-phase circuits are merely a combination of two single-phase circuits, it is necessary to divide the quantity of power to be transmitted by 2, and calculate as above. This is equivalent to using formula (3) for three-phase circuits, given below.

Three-Phase Circuits

To apply the tables to the calculation of three-phase circuits, we proceed exactly as in the case of a single-phase circuit, but, owing to the fact that the drop in a three-phase circuit is the same as that in a single-phase circuit, transmitting half the power, our formula becomes:—

$$\text{Constant} = \frac{\text{Distance in feet} \times \text{K.W.}}{2 \times \text{Regulation}} \qquad (3)$$

or conversely:—

$$\%\ \text{Regulation} = \frac{\text{Distance feet} \times \text{K.W.}}{2 \times K} \qquad (4)$$

Example—It is required to transmit 50 K.W. at 80% P.F., a distance of 10 miles, by means of a three-phase, 60 cycle, 4,000-volt line, with a regulation or voltage drop of 10%. What size wire is necessary?

$$\text{Constant} = \frac{5280 \times 10 \times 50}{2 \times 10} = 132{,}000$$

which corresponds to a wire between No. 6 and No. 7 copper.

For mechanical and other reasons, No. 6 would no doubt be chosen and therefore the regulation using No. 6 wire under the above set of conditions would be

$$\%\ \text{Regulation} = \frac{5280 \times 10 \times 50}{2 \times 156{,}366} = 8.4\%$$

Mains With Branch Circuits

1. **Fed from one end**—Besides the very simple problems, above outlined, it is possible to calculate complicated networks accurately by this method.

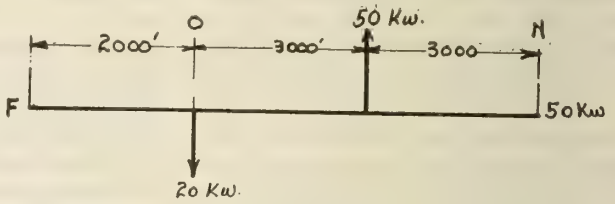

FIG. 1

Example.—Suppose we have a circuit as shown in Fig. 1. Let F be the power source and let the loads be tapped off at intervals as shown in Fig. 1. It is required to find the size of wire that will transmit three-phase power at 2,400 volts, 60 cycles, 65% P.F. and give a 5% drop at N. This problem is solved by adding together the sum of the moments of the various loads about F and dividing by twice regulation desired to get the wire constant, as follows:—

Moment of 20 K.W. about F = 2,000 × 20 = 40,000
Moment of 50 K.W. about F = 5,000 × 50 = 250,000
Moment of 50 K.W. about F = 7,000 × 50 = 350,000

Sum of moments about F = 640,000
Divided by 2 × Regulation = 64,000

We find in the proper table that the size of wire having a wire constant nearest to 64,000 is No. 4, which is the proper size to use.

It is always well to check the carrying capacity of the wire decided upon, as otherwise the safe carrying capacity for a given wire may be exceeded in cases where a large amount of power is to be transmitted a short distance at a comparatively high voltage.

In the above case, the total amount of power to be transmitted is 120 K.W., which, at 2,400 volts, corresponds to a current in each wire of 45 amperes. The safe carrying capacity

of No. 4 copper is 92 amperes; therefore, it is safe to use No. 4 for this installation.

It may be required to find the regulation at some other point in the circuit, as at O. Up to this point the conductor is transmitting 120 K.W. a distance of 2,000 ft. The constant K for No. 4 copper at 2,400 V., 65% P.F. and 60 cycles is 68,305; therefore the

$$\text{Percentage drop} = \frac{120 \times 2000}{68{,}305} = 3.5\%$$

2. **Fed from both ends.**—Sometimes we have a stretch of line fed from both ends at the same voltage. Consider such a case as shown in Fig. 2.

Let F_1 and F_2 be the two feeding points and let loads be tapped off at various intervals as shown in Fig. 2. It is evident that there will be a fall in potential from each feeding point outwards and there will be some point in the circuit at which the potential has a minimum value. Let us assume M as being the point of minimum potential. Now, the load which branches off at M will be fed partly from F_1 and partly from F_2. Let X_1 and X_2 denote the two quantities of power supplied to the point M from F_1 and F_2 respectively and let Im denote the total load which branches off at M.

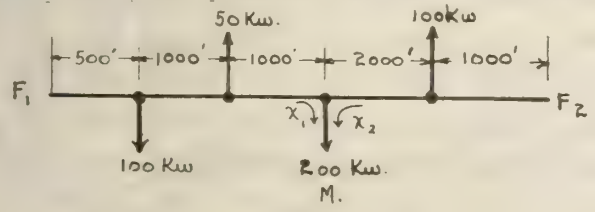

FIG. 2.

Then $X_1 + X_2 = I.m$ (a)

AMPERES PER K.W., PER PHASE, AT STATED VOLTAGE AND POWER FACTOR

Voltage	Single Phase			Three Phase		
	65% P.F.	80% P.F.	95% P.F.	65% P.F.	80% P.F.	95% P.F.
120	12.8	10.-	8.7	7.4	6.0	5.1
240	6.4	5.2	4.4	3.2	3.0	2.5
480	3.2	2.6	2.2	1.6	1.5	1.25
600	2.6	2.0	1.8	1.5	1.2	1.05
2400	.64	.52	.43	.4	.3	.26
4000	.38	.32	.25	.22	.18	.15

A second equation is given by—

Drop in potential from F to M = drop in potential from F_2 to M (b)

If you wish to find the percentage regulation at the point M, we must first find the values of X_1 and X_2. This can be done by using the system of moments. Starting from the two feeding points, write down in two parallel columns the moments of the various loads about the two feeding points, proceeding along each column at such a rate as to keep the sum of the moments as nearly as possible the same in each column. The point of lowest potential is thus reached and the quantities X_1 and X_2 are determined by means of the equations (a) and (b). In the circuit shown in Fig. 2, consider that power is being transmitted at 2,400 volts, three-phase, 60 cycles and 80% P.F., the loads tapped off, as shown. Find the size of wire necessary, in order that the regulation at M may be 2%. In order to find the value of X_1 and X_2,

TABLE FOR CALCULATING A..C. CIRCUITS

Size Wire		Carrying Cap. Amps.	110 - 120 Volts: Constant K for 60 cycles			110 - 120 Volts: Constant K for 25 cycles			220 - 240 Volts: Constant K for 60 cycles			220 - 240 Volts: Constant K for 25 cycles

write down the moments about F_1 and F_2, as follows:—

M of 100 K.W. about F_1 = 50,000
M of 50 K.W. about F_1 = 75,000

Sum about F_1 = 125,000
M of 100 K.W. about F_2 = 100,000

Sum about F_2 100,000

Now, $X_1 + X_2 = 200$ K.W.

$125{,}000 + X_1 \times 2{,}500 = 100{,}000 + X_2 \times 3{,}000$

or

$25X_1 - 30X_2 = -250$

$X_1 + X_2 = 200$

Here we have two simultaneous equations

and $25X_1 - 30X_2 = -250$

$25X_1 - 25X_2 = 5{,}000$

Subtracting, we get

$-55X_2 = -5{,}250$

$X_1 = 106.5$ K.W.
$X_2 = 93.5$ K.W.

In order to find the size of wire, take moments about F_1.

Moment of 100 K.W. about $F_1 = 500 \times 100 = 50{,}000$
Moment of 50 K.W. about $F_1 = 1{,}500 \times 50 = 75{,}000$
Moment of 106.5 K.W. about $F_1 = 2{,}500 \times 106.5 = 266{,}250$

Sum of moments about F 391,250

$$\therefore \text{Constant K} \quad \frac{391{,}250}{2 \times 2} = 97{,}815$$

which corresponds with a No. 3 copper wire, and it is therefore probable that No. 2 copper would be used. Either wire has ample current carrying capacity.

If No. 2 copper were used, the regulation at M would be as follows:—

$$\% \text{ regulation} = \frac{\text{Sum of moments}}{2 \times \text{constant for No. 2 Cu}} = \frac{391{,}250}{2 \times 118{,}730} = 1.6\%$$

Electricity and Hydraulics

PRINCIPLES AND OPERATION OF MODERN ELECTRICAL EQUIPMENT IX.

By A. M. Pere

IN the previous lesson some of the characteristics of the generator and motor field windings were given, and some indication as to how any particular type of machine would function when used as a dynamo or motor. In the generator the speed is

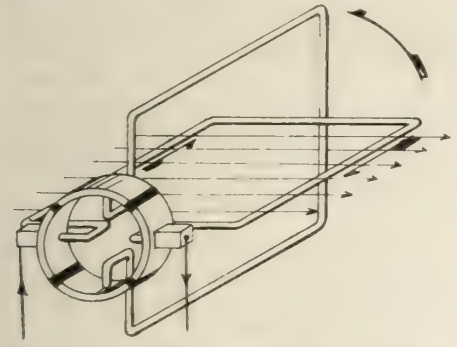

FIG. 1—ARMATURE CONSISTING OF TWO COILS. ACTING AS A MOTOR. THE ARMATURE TENDS TO REVOLVE IN THE DIRECTION INDICATED BY THE ARROW UNDER THE CONDITIONS ASSUMED FOR CURRENT AND FLUX DIRECTION.

governed by the driving agency whatever it may be, and the voltage is dependent upon the speed, other conditions remaining the same. In the motor the voltage is usually somewhat constant, and the speed depends not only upon this voltage but upon the counter-electro-motive force generated in the armature, and increases as the field flux and excitation are decreased.

In the armature of the motor or generator there is always a magnetic drag present on the conductors of the armature. In the generator as was seen in a former section of the course the armature conductors are forced to revolve in a direction opposed to this magnetic drag and energy is used up in consequence. In the motor the armature is free to revolve with the magnetic drag of the field flux on the conductors, and gives out power through this action of the magnetic flux on conductors carrying current.

This force exerted upon a conductor in a magnetic field is always present whether the current is being generated or used to produce work, and as before stated the direction of rotation in the generator is opposed to it while in the motor it is in the same sense.

The counter-electro-motive force of an electric motor, abbreviated c.e.m.f., is of considerable importance in the study of direct current motors, as the operation of the machine and its speed are dependent upon the fact that such a current is generated.

Fig. 1 shows a motor armature very much simplified, with the current flowing in the direction indicated, and the magnetic flux in the direction indicated, the armature will revolve as shown. Now suppose that the same armature be driven in the same direction as before. It will now act as a generator, but the current generated will flow in a direction opposite to that in which it was sent when the armature was used as a motor, see Fig. 2. Both these actions take place in the motor for, as the conductors are moved through the magnetic field under the influence of the current supplied, they must necessarily cut the magnetic flux and in doing so must generate potential. This potential must be opposed to that causing the current to flow through the armature from the outside source, as will be seen from the right and left hand rules here reproduced, see Figs. 3 and 4.

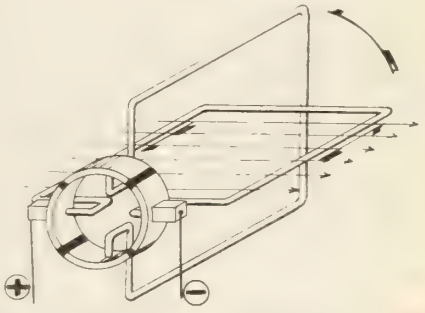

FIG. 2—ARMATURE CONSISTING OF TWO COILS. SHOWING THE DIRECTION OF CURRENT FLOW WHICH TENDS TO BE SET UP OWING TO DYNAMO ACTION, THE ROTATION BEING IN THE SAME DIRECTION AS FIG. 1

Therefore there will be two electro-motive forces at work in the armature conductors, one impressed upon the armature from the outside source causing it to rotate as a motor; the other an e.m.f. generated in the armature conductors themselves by the cutting of the lines of force, and opposed to the exterior source of potential.

$$\frac{\text{Applied voltage} - \text{Counter e.m.f.}}{\text{Armature Resistance}} = \text{Armature current}$$

Since these two e.m.f.'s are opposed the effective e.m.f. which causes the current to flow will be their difference, and the current flowing may be represented as follows:

The counter e.m.f. of a motor must always be lower than the applied voltage, for if it were equal to current would flow at all, and the armature motion depends upon the fact that we have current flowing in a magnetic field. The moment the armature of a motor begins to slow down in consequence of the load being increased, an interesting action takes place which is

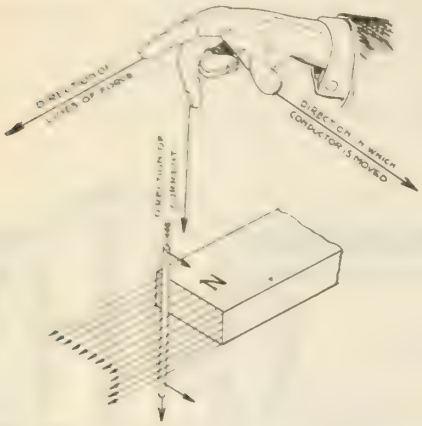

FIG. 3—FLUX CURRENT RELATIONS IN THE DYNAMO AND RIGHT HAND RULE FOR REMEMBERING SAME.

well worth while following through somewhat carefully.

The e.m.f. produced in a generator is proportional to the rate at which the armature conductors cut the magnetic flux produced by the fields. That is to say that if the flux were increased to twice the amount, the e.m.f. would be twice as great and if the speed were twice as great the e.m.f. would likewise double. If the speed were decreased while the field strength were kept constant, the e.m.f. of the generator would be decreased because the total number of lines of force cut in one-second would be less than before. It follows that the instant the armature of a motor slows down, the counter e.m.f. will be decreased so that if it were possible to have the counter e.m.f. equal to the applied voltage, the motor slowing down would cause a decrease in the counter e.m.f. until such a value were reached that sufficient current would flow to keep it revolving.

If the motor is running idle, the c.e.m.f. closely approaches the applied voltage, and only enough current flows to take care of machine losses, such as friction, etc., but the moment load is thrown on the speed drops and the c.e.m.f. in consequence is lowered until enough current flows to establish stable speed conditions.

Provided the supply voltage remains constant we would find a certain definite speed for each load, and the greater the load the lower the speed. The amount of change in speed for change in load differs greatly with various types of motors. The shunt motor suffers the least change, the series motor the most and the compound wound machine is somewhere midway between the two depending upon its field windings. The difference between the applied voltage, and the counter e.m.f. is never very great. This may be shown by means of an example. If a 10 h.p. 220 volt motor whose armature resistance is 0.2 ohm is carrying full load, it will be delivering 10 by 746 watts of electrical energy in the form of power, or 7,460 watts, 746 watts being the electrical equivalent of one horse-power. The current consumed, neglecting machine losses, would be 7,460 ÷ 220, which equals 34 amperes, nearly. Since we have a current of 34 amperes flowing through a resistance of 0.2 ohm there will be a voltage drop of 3.4 by 0.2 = 6.8 volts, and the counter e.m.f. must make up the difference between this and the terminal voltage of 220, or the c.e.m.f. is 220 — 6 8 = 213.2 volts.

Suppose the c.e.m.f. were only 100 volts, the voltage then causing current flow would be 220—100=120 volts, which would cause a current of 120÷ 0.2=600 amperes.

Characteristics of The Shunt Motor

When the shunt motor is operated on constant voltage and constant resistance in the field circuit, its speed will usually decrease with an increase in load or armature current. The torque of a shunt motor increases with an increase in armature current, and would vary directly as the armature current if the field strength of the machine remained constant.

The speed of the series motor decreases rapidly with increasing load, and at no load the motor runs away. This is explained by means of the series connection of the fields. As the current due to the load falls off with decreasing load, the field strength is proportionately weakened and in consequence the counter e.m.f. is lowered.

Speed Regulation

With the shunt, or compound motor, the shunt field offers a very convenient

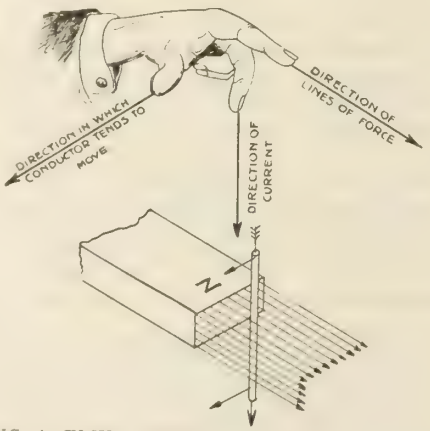

FIG. 4—FLUX CURRENT RELATIONS IN THE MOTOR AND LEFT HAND RULE FOR REMEMBERING SAME.

method of varying the speed of the machine through the adjustment of the field strength by means of a rheostat. When the field current is reduced by means of the rheostat, the counter e.m.f. falls off, and in consequence a larger current flows through the armature. This in turn increases the speed to a point where the counter e.m.f. reaches a value at which the speed is steady. When the field is strengthened, as when the rheostat is cut out, the counter e.m.f. grows larger, cuts down the armature current in consequence and lowers the speed.

Fuel Oil and Its Uses, recently published by Tate-Jones & Co., Inc., Pittsburg, contains information of value to the power plant engineer and those who use fuel oil in furnace work or other industrial processes. A glossary of oil terms is included and the composition and differences of the various oils is explained. Crude oils fall under two classifications, the oils with a paraffin base and those with an asphaltum base. The relation between the specific gravity and the Beaumé reading of oils is clearly set forth and formulae given to change from one to the other. The use of tar as a fuel is treated of at some length and methods for its proper use given. A table gives comparative values of different fuels for equal heat units and a companion table gives the calorific values of various oils according to their specific gravity. Installations for the burning of oil are described, the storage of crude oil, its heating when necessary, oil feeding, piping layouts and burners being some of the points touched upon.

In a pamphlet entitled "Centrifugal Boiler Feed Pumps," the De Laval Steam Turbine Co., Trenton, N.J., describes the De Laval combined steam turbine and centrifugal boiler feed pump. Centrifugal pumps have been used for feeding high-pressure steam boilers for a number of years, but the machine here described differs from those previously used in that the steam turbine rotor and the pump propellers are mounted upon one shaft, with only two bearings and are enclosed within one housing. The combined turbine pump casing is split horizontally, and by lifting the cover all internal and working parts are exposed. The steam and water connections are in the lower part of the casing and are thus not disturbed when the pump is opened. The turbine is of the velocity-stage type, and the pump contains either two or three impellers, according to the boiler pressure.

One of the most remarkable features is the extremely small size and weight of this type of pump. A pump for 3,000 boiler horse-power occupies a floor space of only two by three feet, as against about eight times that space for an ordinary duplex pump. Turbine-driven centrifugal pumps in one housing are made in capacities from 2,000 to 10,000 boiler horse-power. For larger units up to 60,000 horse-power the pump and turbine are built separately, but mounted upon a common base plate. The pamphlet also describes electric motor-driven units.

Turbo-Alternator Rotors: Features of Mechanical Design--II.

A Review of the Conditions Underlying the Mechanical Design of the High-Speed Alternator Rotor—Suggested Specifications For Guidance in Purchasing Equipment

By S. F. BARCLAY, Ph.D., B.Sc.

HEAT TREATMENT

THE rate at which steel cools has a profound effect on its structure and physical properties. The effect of rapidly cooling steel is much debated by metallurgists, and there is no general agreement as to the precise effect.

It has been established that steel has the characteristic of allotropy and its properties vary according to the allotropic form in which it exists. As with most substances, allotropy in steel is a function of temperature with normal

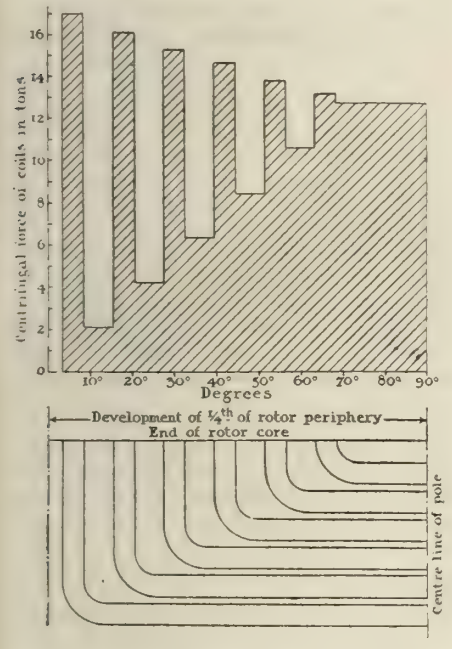

FIG. 11—SHOWING VARIATION IN THE CENTRIFUGAL FORCE OF THE ROTOR COILS IN THE CIRCUMFERENTIAL DIRECTION OF A 5,000 KW., 3,000 REV. PER MIN. ALTERNATOR WITH 31 IN. DIA. ROTOR (CALCULATED AT 20 PER CENT. ABOVE NORMAL SPEED).

cooling as is shown by the recalescence points in the time-temperature curve.

The change, however, from one allotropic form to another requires time, and rapid cooling as is brought about by quenching in oil or water considerably influences the degree of the change. Under a tensile test the performance of steel is apparently little affected by the crystal size, but the resistance to shock and the capacity to withstand reversals of stress are directly influenced. The greater the temperature to which steel is heated the longer it is maintained at high temperature, and the more slowly it is cooled the greater is the crystal size and the less dependable is the steel. A medium carbon steel of the kind suggested for the rotor has its yield point increased about 30 per cent. by oil hardening. It is seen, therefore, that the correct oil treatment of steel very considerably improves its tensile strength, and also puts the steel generally into better condition and makes it more reliable. For these reasons it is very desirable that all alternator rotor forgings should be oil treated The approximate treatment of the steel in question would be to immerse in oil at about 800° C. and temper at about 550° C., the treatment varying according to the carbon content. The heat treatment should be carried out after the forging has been rough turned. Some distortion of the forging is unavoidable in the oven, and the rough-turned dimensions should be somewhat greater than the finished sizes. In an average case the allowance on the diameter should not be less than 0.25 inch.

Rotor End-Bells

As already indicated, the most highly stressed part of the rotor is in the end-bells retaining the rotor end-windings, and the design of the bells, therefore, requires the most careful attention. In the case of a 5,000-k.w. alternator at 3,000 r.p.m. with a 31-in. diameter rotor, at the overspeed of 20 per cent. above normal the centrifugal force exerted by the windings at each end of the core is about 820 tons. If to this is added the centrifugal force of the bell itself, the total centrifugal force at each end is about 2,000 tons. For such enormous forces it is obvious that the material employed must be very high grade.

In the earlier days of the turbo-alternator, steel binding wire was frequently used. The material itself is satisfactory, since it is reliable and has very great strength—an ultimate strength of over 100 tons per square inch being usual, with the yield point not much lower. Two great disadvantages of using binding wire are the difficulty of maintaining a good balance and the necessity for completely re-winding the band if the rotor windings have to be examined. For these and other reasons wire banding is not used on modern turbo-alternators.

In considering the choice of material for the end-bells the designer naturally has preference for non-magnetic material. With the end-bell registering on the rotor core, if it is magnetic it offers a direct leakage path of considerable area from pole to pole, and has an appreciable effect in reducing the useful rotor flux. The leakage has a constant value with a given diameter and excitation, and the percentage value is therefore less the longer the rotor. In the case of an average 5,000-kw. 3,000 r.p.m. alternator at full load the leakage is of the order of 10 per cent. of the excitation energy. Before steel bells were tried it was thought that there might be heating in them due to leakage flux from the stator, but experience shows that such is not the case, the reason being that any such flux rotates synchronously with the bell. It was thought also that for solid bells of any material such as a large mass of metal close to the end of the stator core might cause undue heating due to eddy currents induced by the action of the flux swinging from tooth to tooth. Such, however, is found not to be the case, or if there is

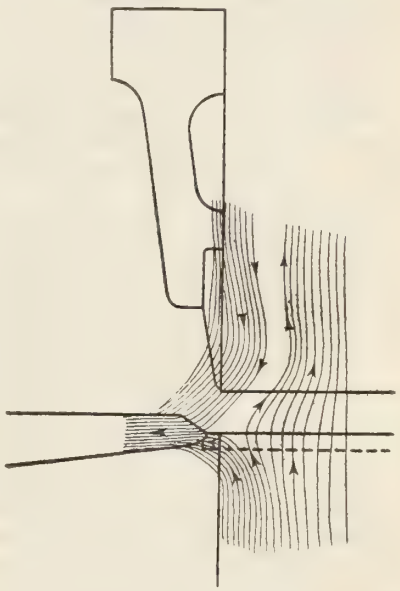

FIG. 12—STATOR LEAKAGE INTO STEEL END-BELL ON SHORT-CIRCUIT.

any such action it is not important in degree.

The magnetic end-bells appear to have one rather remarkable effect in causing great heating in some cases at the ends of the stator core when running on short-circuit. In one case that came to the author's notice of a 5,000-kw. 1,500 r.p.m. alternator with steel end-bells, when running on short-circuit the stator end-plates and the laminations in the immediate neighborhood became very hot; embedded thermocouples placed about 2 inches from the end of the core showed a rise of 150 degrees F. Thermometers placed against the back of the core also showed a high temperature rise in the immediate vicinity of the end-plates and a low temperature elsewhere. On full load the end-plates were quite cool, and the temperatures shown by the thermometers and thermo-couples were quite normal. In two cases of 5,000-kw. alternators at 3,000 r.p.m. there was similar heating at the ends of the stator

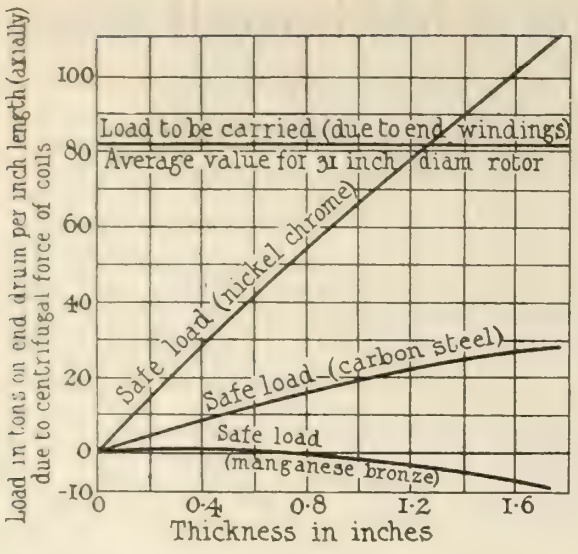

FIG. 13—5,000 KW., 3,000 R.P.M. ALTERNATOR. (CALCULATIONS MADE AT 20 PER CENT. ABOVE NORMAL SPEED).

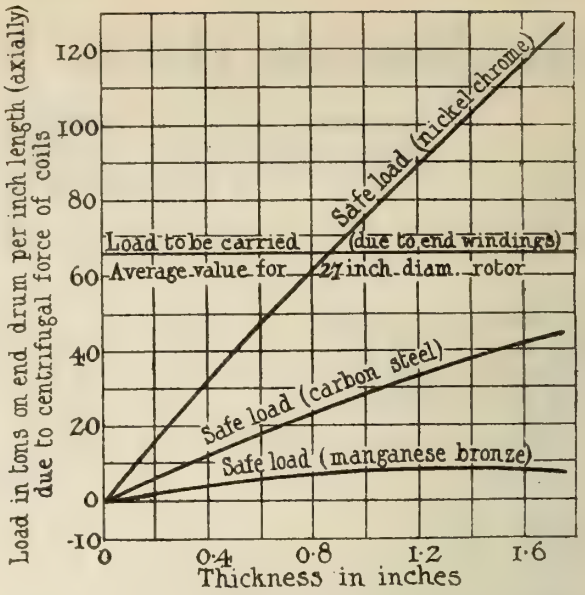

FIG. 14—3,000 KW., 3,000 R.P.M. ALTERNATOR. (CALCULATIONS MADE AT 20 PER CENT. ABOVE NORMAL SPEED).

core in a still more marked degree. Embedded thermo-couples placed ½ inch from the end of the core showed a rise of 250 degrees F. after an hour's run on short-circuit. The temperature rise of the cast-iron end-plates was about 120 degrees F., showing that the greatest heating was in the laminations themselves.

The author suggests that this phenomenon is probably due to the steel end-bells. When a short-circuit test is made with an alternator the excitation is increased until the current reaches its full-load value. The stator current lags almost 90°, and the reaction is in phase with the rotor flux and in opposition to it. Most of the rotor excitation is required to overcome the stator reaction. The leakage into the end-bells weakens the rotor magnetism at the ends of the core, and quite conceivably the stator reaction may overcome it and there may be an appreciable flow of reverse flux between the ends of the stator and the end-bells. The reaction between these fluxes flowing in different directions at the ends of the stator core may quite well cause some of the reverse flux to flow obliquely through the plates and so cause heavy eddy-current loss. Probably also there is a small leakage of flux into the stator end-plates. The effect is indicated roughly in Fig. 12. Since the effect, whatever the explanation may be, does not occur under any running condition, it is of little importance. It may, however, quite upset the method some makers have of forecasting the temperature rise on load from light-load tests—with which one factor is the temperature rise on short-circuit. Moreover, it may cause the designer to attribute to eddy-current loss in the copper a loss that is due to something else altogether.

Of the non-ferrous metals available for making end-bells the best is a high-grade manganese-bronze. Good material of this kind has an ultimate strength of about 44 tons per square inch, a yield point of 22 tons per square inch, and an elongation of 20 per cent. The real elastic limit of the material as shown by its behaviour under reversals of stress is lower with regard to the yield point than with a good steel. For this reason the author is of opinion that the maximum stress should not exceed 45 per cent. of the yield point. In Figs. 13, 14, 15, 16 and 17 are shown the average load per axial linear inch that the end-bell has to carry due to the centrifugal force of the end coils for rotors for 3,000 r.p.m. of 31-in., 27-in., 25-in., 22-in. and 20-in. diameter respectively, calculated at the overspeed of 20 per cent. above normal. The bottom curve in each case shows for various

thicknesses the load that the manganese-bronze can carry in addition to itself with a stress equal to about 45 per cent. of the yield point—i.e., 10 tons per square inch. With a 31-in. diameter rotor it will be seen that the manganese-bronze can only just carry itself when its thickness is varied from 0 up to about 0.7 inch. If the thickness is further increased the stress is increased and exceeds the safe value for the material. With the 27-in. diameter rotor the manganese-bronze has a maximum load-carrying value when the thickness is about 1.5 inch, but it can then carry only about 8.5 tons per linear inch out of about 66 tons that have to be carried. With the 25-in. diameter rotor with a bell thickness of 1.7 inch the bronze can carry only about 22 tons per inch against 48 tons to be carried. For the 22-in. diameter rotor the bronze bell is satisfactory if it is given a thickness of 1.25 inch, and for a rotor of 20-in. diameter it is satisfactory when 0.9 inch thick. These diagrams thus show clearly the extent to which the material may be used—i.e., that it is satisfactory for 3,000 r.p.m. rotors up to about 22-in. diameter.

Figs. 15, 16 and 17 show that oil-treated carbon steel can be used satisfactorily for the end-bells of rotors up to about 25-in. diameter at 3,000 r.p.m., but not for any larger diameters. The curves for the carbon and for the nickel-chrome steel are based on working at 50 per cent. of the yield point of the material, the carbon steel having a yield point of 22 tons per square inch and the nickel-chrome steel 40 tons per square inch. Even for the smaller diameters, however, there are advantages in favor of using nickel-chrome steel. For instance, for the 25-in. diameter rotor (Fig. 15) it will be seen that a thickness of 1.43 inch is necessary for carbon steel, whereas with the nickel-chrome steel 0.6 inch would be sufficient. The magnetic

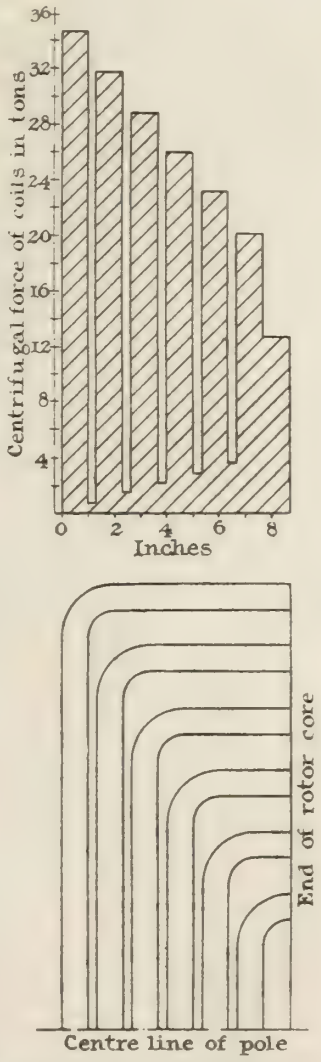

FIG. 19—SHOWING THE VARIATION IN CENTRIFUGAL FORCE OF THE ROTOR COILS IN THE AXIAL DIRECTION OF A 5,000 K.W., 3,000 R.P.M. ALTERNATOR, WITH A 31-IN. DIAM. ROTOR. (CALCULATED AT 20 PER CENT. ABOVE NORMAL SPEED.

leakage with the nickel-chrome steel would be much less and the flow of the ventilating air into the air gap would be less restricted. For rotors more than 25 inches in diameter nickel-chrome steel should always be used. Nickel-chrome steel containing about 3.5 per cent. nickel, 0.5 per cent. chromium, and 0.25 per cent. carbon has an ultimate strength of about 50 tons per square inch, a yield point of 40 tons, and an elongation of 18 per cent. on a 2-in. test-piece, and a reduction of area of 50 per cent.

Of the non-magnetic steels 25 per cent. nickel is the only kind of which the use has been suggested for end-bells. This material, having the approximate composition of 25 per cent. nickel, 4 per cent. chromium, and 0.36 per cent. carbon, has the ultimate strength of about 42 tons per square inch and an elongation of 40 per cent. on 4 inches. The observed yield point is about 25 tons per square inch, but the real elastic limit is very low. With a careful test the extensometer shows a slight permanent set with a loading as low as 15 tons per square inch, and of course the real elastic limit must be at a still lower stress. The steel is not difficult to machine and can be drawn satisfactorily into wire. It is difficult to forge, however, there being a marked tendency for the red-hot billet to crack under the hammer. It is annealed by quenching in water at about 1,450° F. The steel is not magnetic, for the reason that at ordinary temperatures it exists in the same allotropic form as does iron heated above its highest recalescence point—i.e., about 900° C. If the non-magnetic steel is immersed in liquid air it is changed into the same allotropic form as is iron cooled below about 760° C., and it becomes magnetic. 25 per cent. nickel steel is quite unsuitable for high duty, and manganese-bronze, with its higher yield point and more reliable qualities, should always be used in preference.

Hadfield's manganese steel is quite unsuitable for end-bells, having a very low yield point and having the remarkable quality that, although really soft, deformation makes it extraordinarily hard and it cannot be machined. Another non-magnetic steel also unsuitable is that due to Carpenter, Hadfield,

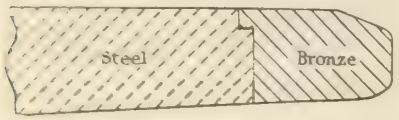

FIG. 20 COMPOSITE END BELL FOR HIGH SPEED ROTOR.

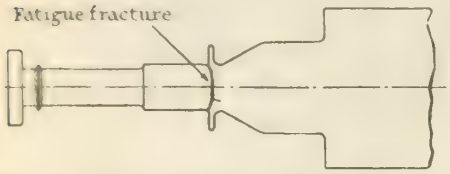

FIG. 21—SOLID FORGED ROTOR WITH DEFECTIVE SHAFT DESIGN.

and Longmuir, containing 19.91 per cent. nickel, 0.41 per cent. carbon, and 0.96 per cent. manganese.

Magnetization appears to be due to the arrangement of the atoms in the molecule, or of the molecules themselves, and is not a property peculiar to the atoms of those elements that are magnetic. There is the effective proof furnished by Heusler* that an alloy containing only non-magnetic elements may be magnetic. He produced such an alloy composed of 60 per cent. copper, 26 per cent. manganese, and 14 per cent. aluminum, all of which elements are non-magnetic. On the other hand, alloys containing a large percentage of iron may be non-magnetic—such as 25 per cent. nickel having about 70 per cent. of iron, and Hadfield's Austenitic manganese steel containing about 88 per cent. of iron. Heusler's magnetic alloy undergoes allotropic change when quenched at 400° C. and becomes magnetic.* Hadfield's manganese steel undergoes allotropic change when it is deformed and becomes magnetic.** The non-magnetic steel of Carpenter, Hadfield and Longmuir behaves similarly.†

Whereas with carbon steel oil treatment is desirable, with nickel-chrome it is indispensable. As with the rotor, the end-bell forgings should be rough-turned and then be heat treated.

As an alternative to the magnetic and non-magnetic end-bells, there may be considered the question of a composite end-bell. The centrifugal force of the coils varies in the axial direction, being least at the core end and a maximum at the other end. In Fig. 19 is given a curve showing this variation in the case of a 26-in. diameter rotor for 3,000 r.p.m. with six concentric rotor coils. It will be seen that the load on the end-bell is appreciably lower near the stator than the average value. For a 25-in. diameter rotor, for which a manganese-bronze bell could not be used, it would be permissible to employ a composite bell of steel with a relatively narrow band of manganese-bronze next to the core. Such a bell is shown in Fig. 20. The saving in magnetization loss with such a construction as compared with the all-steel bell may be of the order of 50 per cent. The author's view is that the all-steel nickel-chrome end-bell represents the preferable construction, and that the composite bell should be employed only in exceptional circumstances. With the composite bell it is important to remember that the elasticity of manganese-bronze is about 20,000,000 lb. (inch units) against 29,500,000 lb. for steel; that is to say, for a given stress the manganese-bronze stretches (elastically) 47½ per cent. more than steel. It is important for this reason that the manganese-bronze ring should be registered on the steel ring, and not under it, so that it is free to open. If the bronze were registered under the steel, the projecting lip would prevent the bronze opening sufficiently (elastically) to carry its share of the load, and the lip might be overstressed. The correct construction is shown in Fig. 20. The author has heard of failures due to this obvious precaution not being taken.

The usual design of end-bell is a cylinder registering on the rotor core at one end and on a disc shrunk on to the shaft at the other. In the case of a 5,000 kw. 3,000 r.p.m. alternator the cylinder opens about 0.03 inch in diameter. It is not possible to give the cylinder sufficient initial tension by press fit to prevent it opening in this way. The tendency of the coil loading (see Fig. 11) is to make the cylinder become elliptical, but since there is nothing to centre it definitely it may move bodily out of centre by the amount it opens radially. The vibration with some alternators that cannot be corrected completely is probably due to this cause in some cases. The author is very strongly in favor of making the cylinder and the end disc down to the shaft in a single piece as shown in Fig. 23; the bell is thus definitely centred and eccentricity is prevented. An additional advantage of this design is that it is not necessary to register the bell on the rotor core and an appreciable gap can be provided between the core and the bell, so reducing the magnetic leakage. The short length of coil between the core and the bell is supported by extending the slot wedge and by registering the end of the wedge under the bell. Another advantage that may be obtained with this construction is to make the seating on the shaft larger in diameter than the slip-rings, so that the end-bells may be removed for examination or repair of the windings without interfering with the slip-rings or the connections to them. The construction also has the advantage of very considerably strengthening the cylinder at the end where it is most heavily loaded. In Fig. 18 is shown the average thickness of end-bell required for rotors of various diameters for manganese-bronze, carbon steel, and nickel-chrome steel.

Ventilation

The various systems of ventilation that have been tried at various times have now settled down roughly to two distinct types—axial and radial. The advantages of the axial systems are that the omission of the radial ducts shortens the machine and that the rotor may be separately and positively ventilated. The disadvantage of this system is that there is an appreciable difference of temperature between the two ends of the machine. The temperature difference may be reduced somewhat by arranging the flow of air through the rotor and stator in opposite directions. With the radial system the temperature rise can be eptk almost uniform from end to end, but there are the disadvantages that the most useful material is removed from the rotor in forming the radial ducts and that the rotor ventilation is not positive. The flow of air through the rotor is induced only by the natural fanning effect of the radial ducts, and the flow is opposed by the pressure in the gap set up by the fans. With large machines the air velocity through the stator has to be made high for the necessary volume of air to flow, and pressure equal to 6 inches or 7 inches of water has to be set up by the fans. At the ends of the rotor such a pressure quite overcomes the rotor fanning effect, and the discharge from the rotor ducts must be prevented if not actually reversed. It is probably only towards the centre of the core, where the air-gap pressure is reduced,

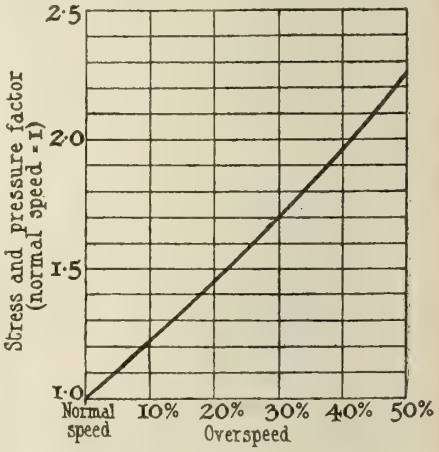

FIG. 22

that there is any appreciable flow of air from the rotor.

The author considers the ideal system to be to have radial ventilation for the stator with independent axial ventilation for the rotor as shown in Fig. 23. The air for the rotor and stator is kept quite separate and the volume and temperature rise of it can be separately measured. By varying the rotor fan the volume of air flowing through the rotor can be regulated to give the exact volume required. The omission of the rotor axial ducts gives the designer liberty to work to the tooth density he prefers rather

†Journal of the Iron and Steel Institute, vol. 69, p. 132.

‡Eleventh Report of the Alloys Research Committee, Institution of Mechanical Engineers, 1905, p. 949.

than that to which he may be forced. There must be some difference of temperature between the two ends of the rotor, but the volume of air can be made sufficient to keep the hotter end within the desired limit. By suitably disposing the stator ducts the temperature throughout can be kept substantially uniform. In addition, when necessary, axial ducts may be arranged in the stator and the discharge from these into the various radial ducts may be separately varied to further equalize the temperature rise. The omission of the radial ducts reduces somewhat the noise of the alternator and also the windage loss.

Fans.—It is quite usual to see with an otherwise well-designed rotor, fans that are anything but robust in construction. Sheet steel about 1-16 inch thick for the blades and about ⅛ inch thick or less for the runners is frequently employed, and apparently that the fans will be satisfactory is taken for granted and is not verified by calculation. Several cases have come to the author's notice of such fans collapsing and striking the stator end-windings with complete breakdown of the alternator. For silent running the more blades the better, but on the other hand the more blades the greater is the load on the runners. It is unnecessary to postulate that safety must come first, and the permissible number of blades must be determined by the maximum thickness that it is desirable to employ for the runners. By running alternators with and without the fans the author has determined the effect they have on the noise. The difference, though appreciable, is not great. The blades should be given such a thickness that collapse is impossible. For the smaller sizes oil-hardened boiler plate is satisfactory for the blades and runners, but for the larger sizes oil-treated nickel-chrome steel plates should be used.

The loss due to the fans in large high-speed machines is of the order of 20 per cent. of the total windage. It is important that the efficiency should be kept as high as possible, since the loss not only affects the alternator efficiency but also adds to the heating. The entering angle of the blades should be the same as the direction of the flow of air into the fan, so that there is no shock. The leaving angle affects the pressure and the direction of the air more than the efficiency. It is usual to make the blade quite straight, but the pressure is increased if the blade is curved in the direction of rotation. The blades and runners should be given a good smooth finish and be coated with a thin hard varnish. With such fans, on account of the big peripheral speed as compared with the air velocity through the fan, the direction of the air leaving the fan is almost tangential. The air, therefore, does not flow axially from the fan to the gap, but is carried round with a high velocity. This action causes some churning and loss, but on the other hand the stator end connections are well cooled. Probably the resistance to entering the air gap is reduced by the motion, since the air in the gap is being carried round violently by the rotor, but if there are stator axial ducts the flow into them may be less easy.

The author has tried the effect of providing a row of standing blades over the fans to make the air flow purely radially into the end chamber. The air pressure was increased about 15 per cent.; the volume of air flowing through the machine was increased correspondingly, and it was therefore decided that there was no gain or detriment in preventing the circular movement of the air in the end chambers.

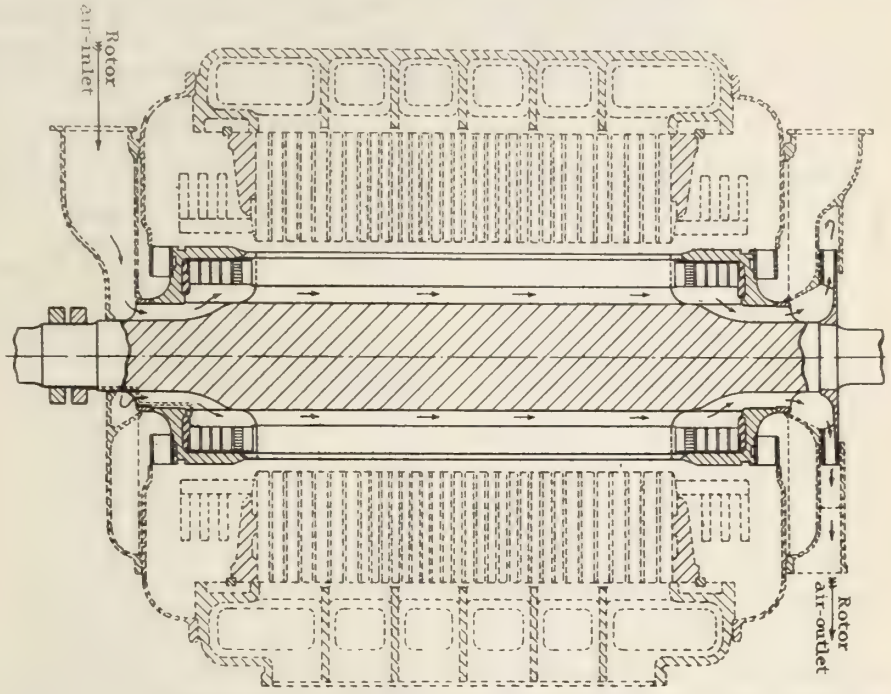

FIG 23—TURBO ALTERNATOR WITH AUXILIARY VENTILATED ROTOR AND RADIALLY VENTED STATOR.

Noise.—With very high peripheral speeds more noise must be expected than with the lower speeds of a few years ago. A good deal of the noise from an alternator is transmitted through the air leaving it, and the station can be made much quieter if the discharge air is led away through a duct. With a new station there is little difficulty in accommodating the discharge duct in the foundation, and for large high-speed sets it is very desirable to adopt this arrangement.

Balance

Freedom from vibration is an essential mechanical requirement apart from being desirable for more obvious reasons. With marked vibration, wear of rubbing parts may take place at an extraordinary rate and the soundest construction be weakened in the course of time. A press fit that would be perfectly solid in normal circumstances may become free in the presence of vibration, and relative movement of the parts may take place. Movement of the end windings is more probable, and the insulation under great pressure is very likely to suffer wear. Every component part should be so designed that change of balance is safeguarded against. It is desirable that the degree of balancing should not be left to the judgment of the erecting engineer, but should be put on a positive basis by using a vibration indicator. The grooves for the balance weights should be provided in the disc supporting the bell cylinder; the practice of attaching balance weights to the outer fan runners is most unsound. Much time is saved in balancing, and the final result is often better if the rotor is balanced statically before running. Although the correct division of the balance weights between the two ends of the rotor cannot be determined statically, the total weight required is determined and adjustment of it only is required when making the running balance. The sensitiveness of the knife edges is much increased by resting the shaft on ball or roller races.

Overspeed Test

The stresses and pressures for a given rotor increase with the square of the speed. The increase of stress and pressure factors at overspeeds are shown in Fig. 22 based on unity at the normal speed. For proving mechanical soundness the overspeed test fails because it is fatigue failure that is most to be feared, and an increase of speed does not prove capacity to withstand fatigue. The overspeed does directly test the soundness of the rotor teeth and of the end-bells, but even its value in this way is limited because in the event of there being a flaw, due to the ductile quality of the steel, it is more probable that failure will result after prolonged running than at the moment. A great disadvantage is that the overspeed imposes an undue stress on the insulation that is harmful. The turbine emergency governor should be set to operate at 10 per cent. overspeed, and since some allowance to make sure of the governor operating is necessary it is desirable that the set should be capable of standing an overspeed of 20 per cent. At this overspeed the pressure and the centrifugal force are 44 per

Notes on Lignite, Its Characteristics and Utilization

A Summary of Present Information on the Composition and Utilization of Lignite is Being Prepared by the U.S. Bureau of Mines—The Following is an Extensive Abstract of the Paper and Should be Read in Conjunction With the Bureau of Mines Bulletin No. 89, and the Report of the Carbonizing and Briquetting of Lignite Published by the Government of Saskatchewan

By S. M. DARLING

CLASSIFICATION OF COALS

THIS classification rests partly on the percentages of volatile matter, oxygen and moisture contained in the coals. There is, speaking generally, a progressive loss of these elements in passing from lignite to anthracite, but chemical criteria alone are not a sufficient basis for such classification. The dividing line is really determined by physical characteristics that directly affect the market value of the coals.

Although subbituminous coals generally have more moisture than bituminous coals, there are so many exceptions to this rule that it has little value as a means of distinction. But there is a very marked difference in behaviour on weathering. The subbituminous coals, on exposure, give up their moisture more readily; as a result they shrink, crack irregularly, and in a measure disintegrate, whereas the bituminous coals shrink very little and show practically no disintegration on drying.

Again, between subbituminous coal and lignite there is no clearly defined chemical difference, but the physical difference is marked. The subbituminous coal is black and shiny, has little trace of woody structure, carries less moisture, and has a greater heating value than lignite, and is capable of producing a coke of fairly good quality. Lignite, on the other hand, is brown, dull, markedly woody in texture, has no coking quality whatever, carries a greater percentage of moisture which it gives up readily, and its disintegration on exposure is so rapid as largely to prevent its shipment any distance, except during the excessive cold northern winters, when it is of course frozen.

The coal resources of the United States totals 3,553,637,100,000 minable tons. Of this total 1,051,290,000,000 tons, or nearly one-third, is lignite. Of this lignite 964,424,000,000 tons are in North and South Dakota and northeastern Montana; in Texas approximately 23,000,000,000 tons; in Alaska, 7,404,300,000 tons; and relatively smaller quantities in several of the other western and southern states (U. S. Geological Survey, Professional Paper 100).

The lignite tonnage given above includes only group 3; it does not include group 2, subbituminous coal, which in earlier days was called "black lignite" and classed in the lowest rank among coals—lignite.

Characteristics of Lignite

It is an important economic consideration that these lignites are found in those parts of the country that have no other solid fuel. They compare substantially as follows:

Average Proximate Analyses of Lignite

	Arkansas	Texas	North Dakota
Moisture	29.73	28.63	27.13
Volatile hydrocarbons	37.87	32.53	29.11
Fixed carbon	23.95	30.43	36.16
Ash	9.45	8.41	7.60

The Alaska lignite closely resembles that of Texas and North Dakota.

The sulphur content of the lignite in these fields rarely exceeds one per cent. The average heating value is about 7,500 British thermal units per pound.

The feature that distinguishes the Arkansas lignite from the others is the high percentage of volatile matter, which yields large quantities of oils and tars.

The large percentage of moisture in lignite has not been absorbed from extraneous sources, but is the portion, partly chemically combined, remaining from the great amount of water present in the peat from which the lignite was derived. This water is poor stuff to pay freight on or put into a furnace; further, its partial evaporation in warm weather causes rapid disintegration or "slacking," reducing the practical shipping radius during warm weather almost to zero. Lignite fires quickly from spontaneous combustion, making safe storage in even small quantities exceedingly difficult. It does not "coke" in the sense that bituminous coal cokes, but rather crumbles when being carbonized, or when thrown on to the fire, and this gives rise to difficulties in firing and substantial loss, as unburned fuel, through the grate bars.

Fuel Needs of Lignite Areas

For these reasons lignite is not a desirable fuel as mined, and millions of tons of bituminous and anthracite coals are shipped annually into the lignite-bearing regions—literally "carrying coals to Newcastle,"—resulting in high prices for both industrial and domestic fuel, imposing a great handicap on the industrial development of these regions, tying up much transportation equipment now urgently needed for other service, and causing other economic lost motion.

Wastes in Present Methods of Burning Coal

The practice of burning high volatile coals on ordinary furnace grates is wasteful.

Our leading engineers and chemists have for many years decried the waste of burning raw bituminous coal. They have time and again shown that it is far more economical to break the coal up by means of carbonization into its constituent elements of solid carbon, gas, ammonia, oils and tars, thus releasing these several valuable products for use in their respective fields.

The fixed carbon is easy to burn because it stays on the grate. The tars and the more complex gases distilled and rising from the fuel bed are quickly decomposed into soot and simple gases, and the soot in large measure passes out of the stack as black smoke, adding the element of nuisance to that of waste. Heat in the form of coal gas brings eight to sixteen times the price of an equivalent amount of heat in the form of coal. Benzol, toluol, and other oils are obtained as a result of this process of carbonization, and the value of heat in this form of motor fuel is twenty to thirty times as great as that of heat in the form of coal. (U. S. Bureau of Mines Bulletin 135.)

Further, the cheapest method of obtaining nitrogen products for explosives or fertilizers is to procure them from the ammoniacal liquor and gas resulting from the carbonization of coal or its gasification in by-product gas producers.

It is undeniable that in the future the principal use of high volatile coals will be in the by-product gas plants because of the higher commercial value of the products of carbonization. It is even suggested that "the time may come when our views of the relative values of the different coals will change and we shall consider anthracite as of minor importance as compared with the high volatile bituminous coals." (U. S. Bureau of Mines Bulletin 135.)

In Bulletin 102, part 4, of the Smithsonian Institution, there appears the following suggestion:

"It is not beyond the bounds of reason to foresee a condition whereby a householder, in the place of his ton of anthracite which he now welcomes for $11, will receive a ton of smokeless coal without slate, a month's supply of cooking gas, 40 miles of motor fuel, enough fertilizer to start a small garden, and tar sufficient to allay the dust in front of his house—all for far less money than he now pays for inferior coal."

This picture is not a fanciful one; our high volatile coals and lignites contain precisely these possibilities within themselves.

The German government, in order to

assure high economy in the utilization of fuel, has practically forbidden the burning of raw coal, compelling the manufacture of coke, gas, tar and other products.

Because of the inherent shortcomings as fuel in the raw lignite itself, one can safely say that it will never be used to any great extent in its raw state. The one fact of its containing 30 per cent. of water would of itself prevent use elsewhere than in the immediate vicinity of the mine. This treatment, or carbonization, of the lignite, therefore, which is absolutely essential to its more general use, is strictly in accordance with modern scientific research. We are simply, from necessity, starting to do with lignite now what will eventually be done with all of our high volatile coals.

Efficient Utilization of Lignite

Some progress has been made in the way of better utilization of lignite. Instructive experiments have been made by the United States Bureau of Mines, the State of North Dakota, and the Province of Saskatchewan, Canada, which bring the matter measurably nearer to a satisfactory solution.

Instead of trying to burn the raw lignite in the primitive and wasteful ways now employed, it should be modified to produce several products, each peculiarly adapted to a particular commercial need, namely:

1. Dried lignite, for use on automatic stokers and in fuel-gas producers. Because of its more or less soft and comminuted condition the dried lignite can not be handled advantageously by hand, but it can be used very satisfactorily by mechanical means.

2. Powdered fuel, from the dried, pulverized lignite, for use in cement kilns, railroad locomotives, and other large furnaces. Because of its high volatile content this pulverized lignite makes an exceptionally good powdered fuel.

3. Dried lignite briquets, for large, hand-fired industrial furnaces and heating plants. Where it is necessary to handle the dried lignite with a fireman's shovel it should be briquetted. Tests of these dried lignite briquets in commercial boiler furnaces have proved them to be equal to good Middle West bituminous coal.

4. Carbonized lignite, for use in suction power-gas producers. Tests of this product in carload lots have proved it to be an exceptional and unexcelled fuel for this purpose. Its chemical composition, as shown by analysis, is about the same as that of Pennsylvania anthracite. In carbonizing the lignite the objectionable tar found in all coals containing a substantial quantity of volatile matter is removed, and the gas goes to the cylinder of the gas engine clean and tar free. For the production of power in this way carbonized lignite is fully equal to anthracite coal, charcoal, or bituminous coke, the standard fuels for such purpose.

This carbonized lignite can also be burned satisfactorily on the automatic stokers and grates used to consume the smaller sizes of anthracite.

5. Carbonized lignite briquets for domestic service in house heating stoves and furnaces, fireplaces, and cooking ranges. This fuel, ton for ton, compares favorably with anthracite coal, and is an ideal domestic fuel in such rigorous climates as those of North Dakota and Alaska. In climates where the thermometer not infrequently goes to 40 below zero this demand is immediate and very large.

6. Sulphate of ammonia and producer gas. The raw lignite, just as it is mined, when used in by-product gas producers of the Mond type, makes sulphate of ammonia, producer gas, and some tars of undetermined value; there is no solid residue except ash. Lignite carries on the average about 1.40 per cent. of nitrogen. If this nitrogen were wholly recovered as sulphate of ammonia the yield would be about 147 pounds per ton of lignite. This theoretical yield of course could not be obtained in commercial practice; the actual yield of sulphate of ammonia per ton of lignite gasified would be 70 to 80 pounds. Ammonium sulphate is now selling for 6 to 7 cents per pound. Before the war it sold for 3 to 3½ cents per pound; but, as the price of this commodity is determined in world markets, it will probably drop back to near the pre-war price when industrial conditions become normal again. The gas yield per ton of lignite would be 60,000 to 70,000 cubic feet of about 140 b.t.u. per cubic foot. This gas could be used as a furnace fuel or in a gas engine to produce power. If the latter, it would yield 700 to 800 horse power hours per ton of lignite gasified.

The fact that the lignite does not coke in the sense that bituminous coal cokes, but rather crumbles on being carbonized, makes possible a continuous and comparatively inexpensive distilling process, thus obviating the laborious and expensive charging and drawing of retorts as practised in coal gas plants. It also parts with its volatile content more readily than does bituminous coal. The entire process is mechanical. The fuel need not be handled by manual labor from the time the lignite is loaded into the mine car until the briquets are en route to the consumer. The costly element of labor is reduced practically to that required for directing mechanical operations.

By-Products From Lignite

In carbonizing the lignite valuable by-products in the form of gas, ammonia, and oils and tar are obtained.

The Gas

The gas yield is upward of 10,000 cubic feet per ton of lignite. The gas has a heating value of 400 to 450 British thermal units per cubic foot.

A little more than one-half of the gas is necessary to carry on the carbonizing process; the balance can be used as a city gas for cooking, or for lighting if burned in a mantle, for furnace fuel, or for generating power by means of a gas engine. Or, if desired, the entire 10,000 cubic feet can be devoted to these purposes and the carbonizing carried on with lignite producer gas from a fuel gas producer.

If the gas should be used as a town gas and a higher thermal value than 400 B.t.u. per cubic foot were required, the whole 10,000 cubic feet can be enriched to the desired point. The director of the oil division of the Fuel Administration has proposed that the heating values of carbureted water gas sold for domestic use shall not be over 528 B.t.u. per cubic foot. Or, in a carbonizing oven of the Saskatchewan type the poorer portion of the gas could be collected separately and only the richer portion, about 7,000 cubic feet, sent into the city mains without enriching. The inferior gas would not be wasted, but could be used as bench fuel, supplemented by producer gas. If it were desirable to do the carbonizing exclusively with the oven gas, the richer portion available for distribution in city mains would be reduced to between 3,000 and 4,000 cubic feet per ton of lignite.

The fact that the sulphur content of lignite is small is a good feature. There is an almost entire absence of the corrosive acid resulting from the combination of sulphur with water when the lignite is burned. Should the lignite gas be used as a "town gas" for heating, cooking and illuminating purposes, there will be almost no sulphuretted hydrogen to be removed by means of hydrated oxide of iron purifiers.

Consider the matter of power. Of the yield of 10,000 cubic feet per ton of lignite carbonized, 6,000 cubic feet are required to carry on the process, leaving a surplus, costing nothing, of 4,000 cubic feet, of 400 British thermal units per cubic foot, or a total of 1,600,000 British thermal units. A good gas engine uses about 10,000 B.t.u. per horsepower hour. This gives 160 horsepower hours from the surplus gas from each ton of lignite carbonized. This power is comparable in cost with that derived from natural gas. It is fully as cheap as most hydroelectric power.

This cheap power, of course, is limited by the quantity of lignite carbonized, but the first need of the people in northern climates is domestic fuel, hence the demand for these carbonized lignite briquets is very large. As the population and the demand for power increase, the demand for this carbonized fuel will increase apace. If the demand for power in any lignite field should outrun this supply of surplus gas the amount of power can be readily and cheaply augmented by the use of carbonized lignite in power gas producers.

The by-products should at least pay the cost of carbonizing and briquetting, thus affording a first rank fuel in place of one of lowest rank, at no additional cost.

It is not necessary to dwell upon the benefits that would ensue to these lignite sections by thus placing them in possession of a fuel equal to anthracite and a supply of cheap electrical power.

And these remarks apply to one-third of the coal resources of the nation.

The Ammonia

The ammonia is contained in the gas and gas water. It may be recovered as ammonium sulphate, a valuable fertilizer, as anhydrous ammonia, for refrigeration and other commercial purposes, or it may

be treated as the source of other nitrogen products, some of which are of vital importance in the manufacture of explosives. As stated above, this and the Mond process are the cheapest sources of these products, but the amount which can be so recovered is limited to the tonnage of coal carbonized or gasified. The manufacturing practices in this connection have long been standardized.

The Oils and Tars

Just what is the most profitable disposition to make of the oil and tar products in this country remains to be determined. This is an industry by itself.

The simple distillation products of this oil can be put to many uses—fuel oil for furnaces and internal combustion engines, creosoting oils for the preservation of timber, waterproofing and preserving oils for leather and cotton and other fabrics, tar paper, roofing pitch, etc.

The pitch makes an excellent binder for the briquets, and will go far toward reducing the cost of this item, if more valuable uses are not found for it. The anthracene and creosote oils will, without doubt, find a ready market as wood and leather preservatives.

From the several fractions, upon exhaustive distillation and treatment, are derived hundreds of synthetic products in the way of paraffin, acids, antiseptics, photographic chemicals, aniline dyes, perfumes, drugs, preservatives, etc.

From the light oils come benzol, toluol, aniline dyes, photo-chemicals, certain drugs, and many other chemical products. From the carbolic and creosote fractions are derived carbolic acid, creosote, picric acid, photo-dyes and chemicals, coloring materials, and numbers of perfumes. The anthracene oils give, among other things, alizarin, a valuable acid used in the production of dyes, and carbolineum, used as a wood preservative. This latter product is analogous and equal in value to the carbolineum derived from European lignite, which before the war was imported in large quantities and retailed at 65 cents per gallon in barrel lots.

At first, of course, the simple distillation products will be procured and marketed as such, but as opportunity affords, each of these primary by-products will be taken up and synthetic chemical products manufactured. The exact course of this development is a matter to be determined in conjunction with a careful study of the market.

Almost all of these manufactured tar products have heretofore come from Germany. In 1913 the United States imported coal tar products of the value of $11,000,000 at initiating points, and these, when they reached the consumer, probably cost double that amount. Millions of gallons of creosoting oils for preserving timbers have been imported annually. That supply is now cut off and the market value of these commodities on this continent greatly enhanced. It is not unreasonable to expect that in the future a large part of this demand for tar products will be supplied from these immense stores of lignite.

Certain Arkansas and Texas lignites are known to be substantially undeveloped cannel coals, containing a large percentage of volatile matter. It is probable that the day will come when we will distill these lignites to recover products similar to the oils now being recovered from the oil shales of Scotland and elsewhere.

Possible Conservation of Petroleum and Natural Gas

The bringing on to the market of the lignite would release large quantities of Texas petroleum and natural gas for other uses, and the conservation of our petroleum resources is a more important matter than the average man appreciates.

Of our original supply of petroleum, 42 barrels per capita have been used, and only 70 barrels per capita remain for the future. About half of the petroleum currently produced is used as fuel for steam raising. The possibilities in the use of petroleum and its products in connection with the navy, airplanes, the merchant marine, automobiles, motor trucks, tractors, etc., are so great and vital that before long it will be looked upon as an inconceivable folly that oil should ever have been used for steam raising, the most glaring economic perversion that this country has ever been guilty of. (Bulletin 102, part 6, U. S. National Museum).

"The whole mechanical equipment of modern civilization is dependent upon lubricants made from petroleum. Its exhaustion spells commercial chaos or commercial subjugation by the nation or nations that control the future source of supply from which petroleum will be derived." (M. L. Requa).

Efforts are being made in France to introduce the distillation of lignite for tars. The Societe de Distillation des Combustibles, Paris, is constructing an improved Ziegler type of furnace similar to that used for the distillation of peat, a type yielding about 7 per cent. of tar.

"In one place in Germany, where the system was adopted, 70 to 80 per cent. of marketable products was obtained from lignite tar, namely 15 to 20 per cent. paraffin wax; 5 to 20 per cent. kerosene; 5 to 15 per cent. of creosotes and organic acids; the remainder being light products, petrol, etc., or heavy products such as gas-oils and lubricating oils.

"Concurrently with the great interest taken in the development of the shale-oil industry in America, it is worth while to consider the possibility of utilizing the large deposits of low-grade lignites for another set of greatly needed chemicals, including the fixed nitrogen which can be converted into ammonium sulphate. Among the available products are benzol and toluol, and the gas can be employed in many places for industrial purposes." (Mining and Scientific Press, May 11, 1918.)

If we are to prevail against our enemies in time of war and maintain our commercial prestige during peace we must not be less diligent than either friends or foes in the matter of developing and conserving our natural resources.

In respect to the world's future demand for fuel oils, the "London Financier," the leading financial paper of London, says in a recent issue:

"Of all the commercial propositions of the world, probably none has greater potentialities than the oil industry. Although throughout the centuries a staple product of the earth, oil, until comparatively recent years, was never utilized to any extent as a motive power owing to the poverty of invention in respect to engines adequate for its proper exploitation in that respect.

"The war, however, has brought about many wonderful changes, necessity having truly proved the mother of invention, and, among other things, oil engine invention has received a vast stimulus, with the result that perfection in the manufacture of the necessary machinery is now being rapidly approached, and, at the same time, scope for the usefulness of liquid fuel enormously extended.

"It is indeed quite reasonable to prophesy that the next generation will witness the practical disappearance of coal as the motive power for railways and ships, so that 'King Oil' may become a greater potentate on both land and sea than the veteran monarch of motion, 'King Coal.'"

A market for the fuel oils derived from carbonization of lignite is assured.

Advantages in Carbonizing Lignite

A number of substantial economies from the mine operators' and coal dealers' standpoint become available through this method of carbonization of the lignite.

The prime advantage is that the lignite is changed from an unstable commodity into several stable and valuable products, the demand for every one of which is large and increasing.

In the use of raw lignite, under present practice thousands of tons of screenings are annually wasted. The coal is forked over in the mine room and screened again at the surface when being loaded into railroad cars. If the problem is handled as outlined above this waste would be eliminated, every pound of clean lignite broken from the seam could be put to some profitable use.

The raw lignite cannot be stored economically; the treated product can, and this results in another large saving, in that it would enable the mines to operate under stable conditions the year around, instead of only during the winter months, as at present.

Some study should also be directed to designing appropriate apparatus for the consumption of these classes of fuels instead of using devices already on the market intended to consume fuels of quite a different character.

Unquestionably the experiments so far conducted open very large economic and commercial possibilities, and it is believed that a little wider and more thorough investigation will point the way for the establishment of carbonizing and briquetting plants throughout the lignite-bearing sections of the country, thus bringing effectively into the industrial world one of our largest natural resources. The results will be not only

the production of a first-class solid fuel, so much needed, but the saving of many by-products valuable in war as well as peace, and the easing of overburdened transportation conditions throughout the country.

In conserving the coal supply and in increasing the electrical power supply of the country, lignite resources must be developed as well as water powers.

With regard to the extent to which we may expect hydro-electric power to take the place of power from coal, the following statement by Steinmetz is interesting and authoritative:

"Assuming an efficiency of 60 per cent. from the stream to the distribution centres, there remain 230 million kilowatts (24-hour service) as the maximum possible hydro-electric power which could be produced if, during all seasons, every river, stream, brook, or little creek throughout its entire length from the spring to the ocean, together with all the waters of the freshets, could be and were used.

"This maximum possible hydraulic energy of 230 million kilowatts is little more than the total energy which we now produce from coal, and is about equal to the present total energy consumption of the country including all forms of energy.

"This is rather startling. It means that the hope that when coal once begins to fail we may use the water powers of the country as a source of energy is, and must remain, a dream; for if to-day all the potential water power of the country were developed, and every drop used, it would not supply our present energy demand.

"Thus hydraulic power may and should supplement coal as a source of power, but can never replace it.

"This probably is the strongest argument for efforts to increase the efficiency of our means of using coal." "General Electric Review," July, 1918.)

There is a very large demand for electrical power in central Texas close to the Texas lignite beds. Water is rarely present in sufficient quantities for condensing purposes in connection with steam turbine power plants. It looks as if the future supply of power for central Texas must come from lignite, used in the raw state in by-product producer gas plants, as carbonized lignite on automatic stokers under boilers or in power gas producers, or as surplus gas from the carbonizing process used in a gas engine.

There are several uses for the lignite retort gas, as a town gas, as a furnace fuel, and in a gas engine. There are also several uses for the carbonized residue, in gas producers, on stokers, or in briquetted form. Therefore it ought not to be difficult to market in one way or another either of these products no matter how large the demand for the other might become. It is not easy reasonably to conceive a limit to the market for sulphate of ammonia or hydrocarbon oils and tars.

These different products can be used in so many ways that an industry of this kind could readily be made to fit the industrial requirements of any ordinary community.

The carbonizing of this lignite will place the lignite-bearing regions on a par from a fuel and power standpoint with those parts of the country that are favored with bituminous coals. It will give a better domestic fuel in the way of carbonized lignite briquets, a better gas producer fuel in the form of carbonized lignite, enormous quantities of gas to be used for fuel or power purposes, large quantities of fertilizer in the form of sulphate ammonia, and a great amount of oils and tars. And the by-products derived from this process should more than pay the cost of making the transformation.

This project of developing our lignite resources is not a small matter.

Take the North Dakota section as an illustration:

Into this section there are now being imported a minimum annual tonnage of two million tons of bituminous coal and one million tons of anthracite, every pound of which should, and some day, will be replaced with fuel from the Dakota lignite field.

To replace these three million tons would require the carbonizing annually of six million tons of lignite, yielding three million tons of solid fuel, eighteen billion cubic feet of surplus gas (costing nothing), forty-five thousand tons of sulphate of ammonia, and sixty million gallons of tar distillates, comprising benzol, carbolic, creosoting and anthracene oils, paraffin, etc.

The waste in dollars and cents involved in two years' importation of the foreign coal into that territory would probably pay for all the equipment necessary to carry on the industry on the scale outlined.

Bear in mind, too, that the Texas lignite situation affords an even greater opportunity for economic saving. The opportunity in Alaska must be nearly, if not quite as large. And there are many smaller deposits of lignite scattered over the southern and western states where relatively smaller savings can be made in similar fashion.

In several sections of Texas there are merchantable deposits of iron ore. Limestone is close at hand. The development of these deposits has been unprofitable because of the high price of coke, but under the present stimulus of high war prices for pig iron, a blast furnace will soon be put into operation at Rusk, notwithstanding the fact that the Alabama coke which will be used will cost $16 per ton at Rusk. The carbonized lignite, or the carbonized lignite briquets, should replace this coke at not more than half the price. The lignite, iron, and limestone lie within a few miles of each other. The development of a steel industry in Texas surely should obviate the necessity of large shipments of iron products from eastern United States into that section.

ERRATUM

In POWER HOUSE for October, in the article on "Burning Lignite with the Mechanical Stoker," line nine should read: 9. Kind of Fuel used on test—Pembina lignite, pea 50 per cent.; slack 50 per cent.

TURBO-ALTERNATOR ROTORS; FEATURE OF MECHANICAL DESIGN

Continued from page 327

cent. greater than at the normal speed. The author holds the view that all parts of the rotor should be designed as if it were to run at 20 per cent. overspeed continuously. At the normal speed the stresses and pressures are 30.5 per cent. less, so that the factors of safety in the teeth and end-bells are then very satisfactory.

In summary, high overspeeds (1) do not test the most important requirement—capacity to withstand fatigue; (2) do not necessarily detect the presence of incipient flaws in the highly-stressed parts; and (3) do undoubtedly tend to damage the insulation. An overspeed of 20 per cent. is essential, but anything higher is undesirable.

In conclusion, the author begs to express his obligation to Mr. Douglas Vickers and Mr. W. Clark, directors of Messrs. Vickers, Ltd., for permission to read this paper. Also he takes the opportunity of acknowledging his indebtedness to his colleague, Mr. J. P. Nicholson, who conducted the various mechanical tests referred to in the paper.

TO ASCERTAIN THE SPEED AND DIRECTION OF AIRPLANES OVER THE WATER

The practicability of flying over long stretches of water is handicapped by the difficulty of determining the direction and speed of flight. Admiral Fiske proposed a means of overcoming this difficulty based on the idea of making an aeroplane follow the same general procedure as a ship does.

For long flights over water the machine should be made to fly quite close to the water and steer a straight course, not only laterally, but vertically, thus enabling the pilot to obtain information concerning the direction and speed of flight from the water itself by means of what may be called "an airplane log."

The direction can be ascertained by towing through the water a small object by means of a long and light steel wire. The small object will always be in the vertical plane containing the fight path, and the direction may be found by attaching the log line to the end of a pointer moving under the compass, or to a "dumb compass' kept in agreement with the compass.

To find the speed it would be necessary merely to tow a "Massey's log"—a simple contrivance towed by a ship and consisting of a sort of box fitted with a propeller that actuates dials on the surface of the box when it turns. The dials indicate the distance the box has been towed, and knowing the time, the speed can be determined. The error that might be made in calculating the speed is estimated at 2 per cent.—"Aerial Age Weekly."

An Expert Engineer Needed

MEMBERS of the Canadian Manufacturers Association, either as a body or from the viewpoint of the largest coal consumers, should make a closer study of the problem of fuel economy than they have ever done before. We do not mean that they should seek to burn less coal, although such a thing might be cimmendable, but of primary importance, see to it that the coal that they buy and pay for is BURNED, not simply reduced to ashes.

From many inquiries made we believe that the number of power plants in Canada that have a high rating of efficiency in coal consumption and steam production is comparatively small. As coal burners they are wonderfully successful. As result-getters they are dismal failures.

There is room for the large fuel consumers to take intelligent action in this matter. It is not for them to look to the government, for the assistance they will get there may be advisory or legislative. The biggest chance is in raising the efficiency of the coal consuming departments of their business, and the place to start is in the boiler and engine room.

There are many plants that cannot afford to engage a competent engineer. Even were they able to pay the price they might not be able to secure the man they needed, for the studious engineer, the student in the game of combustion is not an easy man to find. He's not the is that he shall know just enough to find favor in the eyes common garden variety of engineer whose chief concern of the board of examiners.

The large coal consumers in the C.M.A. would undoubtedly find it to their interests to engage an expert engineer, who could check up the results that are being secured in the power plants concerned, and then proceed to visit the delinquents and find out where they can be put right. If such a man were engaged those engaging him would be entitled to expect results, and it is safe to presume that they would get them, and that they would be more than in keeping with the expense of appointment.

As has been pointed out before in these columns the bombarding of coal burners with government advice is wasted effort. The manufacturers know that coal costs money, and that it is hard to get. From that they can easily figure for themselves that it is good policy to save it and get the most out of it. If they didn't know that much they would have been out of business long ago. What is really needed is expert advice on the bringing of each individual power plant up to an efficiency standard of at least 75 per cent.

Coal Bins and Church Union.

THE Protestant churches in Brockville held union services last winter. It may have been that they were forced to do this because there was a shortage of coal. Against this, however, is the fact that they are doing it cheerfully on a large scale this winter because they want to do it, and have sent a letter to the Ontario fuel controller pledging support.

This sort of business is liable to do quite a heap of good apart from the coal that will be saved, and that should amount to quite a bit, for the average sexton is a pretty fair stoker when it comes to burning coal.

Not only so, but it must be some satisfaction for the pastors to get a chance to preach to a full house now and then. If there's anything that should put a preacher in shape for tremendous action it is a full house. If there's anything that would put the damper on this eloquence and the cold water on his fervor it would be a complement of empty seats. Somehow we've always felt sorry for the pulpiteer who has had to start his day's job with that won't-you-move-up-to-the-front look on his face. He may get off to a good start and keep going right to his "in conclusion," but at the same time he's got a handicap against him that puts him in the class of a lame horse pulling a stone boat.

By all means let the church goers save fuel. Let the Baptists sit in tight up against the Methodists, and let the stalwart Presbyterians be sandwiched with the Congregationalists. Nothing will harm them. Let them vie in matching pennies on the collection plate. Let 'em lift their voices higher than the rafters in praise and worship.

Technical Journal Best Aid to Education

Stationary Engineering Becoming Highly Technical and Specialized Avocation With Increasing Prestige—The Technical Press is Recognized as the Best Means For Procuring Advancement Through Increased Knowledge

By S. BALMFIRTH

IN these days of war, of coal shortage, and rumors of further shortage, the engineer is being called upon for increased efficiency as never before.

Coal, which two years ago was plentiful and fairly cheap, is now scarce, poor in quality (frequently) and high in price.

These conditions have resulted in a demand from manufacturers and governments for a more efficient and economical system of power generation. That is to say both manufacturers and governments are putting the question right up to the engineer as being the man most likely to produce the results required.

However the work of a steam engineer is not learned in a day, but is a long, tedious and very often painful process. The engineer, unlike most of the manual tradesmen, is never out of his apprenticeship. He is like a man rowing a boat upstream; if he stops rowing he drifts back. So it becomes every engineer worthy of the name to keep everlastingly at it. In fact in these days of progress and invention in every line of business, it is absolutely necessary that one devote a fair amount of time to learning the finer points of one's chosen line. Nowadays the up-to-date chief engineer is being classed, at least as a semi-professional man, which is only right for certainly steam engineering has got past the old rule-of-thumb days.

Time was when the fireman of to-day was the engineer of to-morrow. That is, the beginner in the steam engineering profession began as a fireman, and from the experience he got as such, and from his observation of what the engineer did and from what the engineer was willing to show him, he progressed slowly and laboriously until he had sufficient knowledge (or thought he had) to apply for a position as engineer. If he succeeded in getting a position as engineer, his troubles began. Then he found quite frequently that engineering was "not just what it's cracked up to be!" However, if he succeeded in keeping the wheels turning without having to call in outside help, in most cases he would be able to hold down the job long enough for him to learn more about his business.

Of recent years, however, in keeping with the general progress of education the engineer is fast coming into his own.

No longer is he known as "the man in greasy overalls carrying a monkey wrench," although both these articles are very necessary adjuncts, but he is being recognized as a very necessary and important man in any business, by the most prominent manufacturers.

It is not necessary for any engineer to depend entirely upon his own experience for his information. Nowadays there are books published for self education (some of which are suitable and some are not), correspondence schools, free libraries, night schools, engineers' associations and many other ways open to the seeker after knowledge.

The writer has used most of them, with varying success. Experience is, no doubt, the best teacher, but her course is very expensive. So it is very much less costly to use the other fellow's experience.

Any one can profit by his own mistakes, but it takes a wise man to profit by the mistakes of others. Of the sources of information mentioned above each has its good points, and each its disadvantages.

One of the disadvantages of the technical book, is generally speaking, it is not written for self education. It may be intended for that purpose, but very frequently falls far short of fulfilling its purpose. Many of them are couched in language entirely beyond the average engineer's education, and require a teacher to explain. Further, the best book written at once grows old and out of date the moment it is published.

Correspondence schools fill a great want in this regard, in that their text books are generally written for self instruction. Most of them are written in simple language, and carry the student along step by step from the first rudiments of the subject in hand to its final conclusion. Further the correspondence school saves the time required in travelling to and from home and school, and also makes use of any odd minutes that the student may have to spare. The writer put in a good many hours' study on the street cars.

Technical schools, that is evening classes, are an excellent means of providing higher technical education for the man who can attend. But right there is also the disadvantage. No course of lectures will benefit a man unless he can attend all, or at least the largest proportion of them, and the average plant engineer cannot be certain of being able to attend all lectures. Things have a habit of going wrong on class night, and one of the most important lectures is missed, and then the whole course is thrown up in disgust. Then again many engineers cannot attend by reason of the time of their watch, so that they have to forego the benefits of the night class.

Still for those who can attend the night technical school is an ideal means of acquiring an education; combining as it does the use of spare time with both practical and theoretical courses of study.

The engineers' association is a very good means of self improvement; in fact one of the best. If the association is at all alive, discussion of various subjects of interest to all engineers is the main part of the evening's business. Every one has a chance to express his opinion, and many and various are the opinions expressed at times. Still, by discussion one learns, and by friction a polish is given. So that even if one makes mistakes in giving expression to one's opinion, it is not often that one makes the same mistake twice. Then again a mistake made in discussion of any subject is much more easily rectified than a mistake made on the job; it is not likely to be so costly either. The older engineers are always ready to help the younger ones, by giving them the benefit of their experience.

But!——— if you wish to learn about any subject, write about it. One could safely say that what one writes about, one remembers best. Not only that, but what one writes about one generally takes care to be accurate.

So, the technical magazine has a field all its own. In it one can express one's opinion on any subject covered by the magazine. Not only that, but the criticism evoked is often constructive, in fact generally so. Further one can ask any question and be sure of geting an answer. There is generally someone who knows the answer to the question and is willing to pass the information along.

The technical magazine has one great point in its favor, that is, it is never out of date. One can always be sure of finding the latest improvements and the newest inventions in its pages. Then again the adveritsements are a fruitful surcoe of information of what is new and what is standard and reliable, so that, generally speaking,

the technical magazine may be made one of the best means of keeping up to date.

But to the engineer it may also be a source of revenue, besides being a general depot of information. If you have any experience that strikes you as being out of the ordinary, write to your magazine about it. If it's good enough to print, its good enough to pay for. It does not really matter if you never wroter for publication before, if the language you use is ungrammatical, or if your spelling is of an order not mentioned in "Webster's Unabridged"; send it in. The magazine has men whose special job it is to clothe your idea in suitable and proper language and fit it for presentation. If you can make a sketch to help illustrate your idea, all the better. It need not be a scale drawing or an artistic piece of work; if it expresses your idea, the artists on the staff of the magazine will make a good drawing of it.

Possibly a single instance may illustrate the idea. The writer had occasion to give a paper at one association meeting, which dealt with the writer's everyday work. The writer's opinion, when he began to prepare the paper, was that he knew sufficient about the subject to make preparation unnecessary. However, as the paper progressed the writer found that his knowledge of the subject was not quite so full as he thought, so he had to consult various works of reference, but by the time the paper was ready to present the writer knew what he talked about, and in the discussion which followed the paper the writer was able to answer every question and argument. Before the preparation of the paper the writer thought he knew, afterwards he did know. Writing about a subject impresses almost indelibly on the memory.

In the words of the advertisement: "To earn more—learn more." To learn more, write about it. Use your technical magazine.

PERPETUAL MOTION SOME DISTANCE YET

So Don't Lie Awake at Nights Wondering When It Will Respond to Your Own Genius

By J. H. R.

LIKE the measles or the mumps, most of us are afflicted at some time in our career with the idea that perpetual motion is not only feasible, but that we are probably the fortunate individual to discover the secret that has baffled scientific men for many centuries. This lapse of normal consciousness, however, is seldom of long duration, as the majority soon realize that it is a practical impossibility to obtain "something for nothing," a condition that must necessarily exist for such a thing as perpetual motion to become an established fact. To secure motion, be it ever so small, it is necessary to utilize a proportionate amount of energy, so that to attain the movement it is quite obvious that the power must be first generated; therefore, with a little thought the fallacy of perpetual motion will be readily acknowledged by anyone who will take the trouble to study, even briefly, the fundamentals underlying the mechanical sciences. However, advice in this connection will seldom be accepted by those who have once got the bug until they themselves are convinced to the contrary.

The writer himself is one of the many that has experienced the thrill of this visionary flight, but in a short time had to admit that the perpetual part of the task was in the seeking rather than in the achievement of the purpose. A temporary illness in this respect is frequently a good thing, but a prolonged sojourn from the more immediate and practical opportunities may prevent a man from applying his ingenuity to a better and more remunerative cause.

Should a man become persuaded that perpetual motion is to be the product of his own particular brain, it would be well to obtain some data on the subject before expending any time in experimenting, as in many books that have been published there is a more or less comprehensive treatise of those ideas that have encouraged many men to spend weeks, and months, and even years, of their lives in a vain effort to achieve a result that was expected to revolutionize the science of mechanical operations. A perusal of such literature may bring to light a duplicate of the very idea that has become the pet of their wakeful hours and the nightmare of their restless nights.

JUDGE A MAN BY STARTING POINT

Hugh Clark Worked and Asked Questions and Studied All At the Same Time.

EMPLOYEES of the Singer Sewing Machine Works at Clydebank, Scotland, at least those of the old guard whose memories go back 30 to 35 years, could tell you of a lad they all called Hughie. They could tell you how this little more than toddling lad worked in the packing rooms of that 30-acre plant. With reminiscent smiles they could tell you how, along in the year 1888, he soberly announced intention to go with his parents to Canada. And as he fitted the action to the word a few weeks later it is our privilege to report his measure of success in this land of recompense for intelligently directed effort.

HUGH CLARK

Hugh Clark, or "Hughie" still to his intimates, started work in Canada as a carder in the Standard Woollen Mills. With the lapse of 10 years in this Toronto plant he stood at the gateway to the age at which a young man either strikes out for the thing he wants to do most or passively accepts his lot and rears a grouch upon it. He could be a carder to the end of time or he could buckle down to grimy toil and lamentably neglected studies and so fit himself for the work he mightily wanted to do.

To his credit, young Clark arranged for a transfer to the fireroom in the Standard Mills. Here for four years he worked as a fireman in a double sense. That is to say, he stoked, and he fired questions at all and sundry who could let him into the mysteries of boilers, engines and anything and everything mechanical.

And at length, when he was ready, opportunity was ready too. The power plant of the W. A. Murray store, Toronto, needed an assistant engineer. Clark got the job.

Three years later this privately owned plant was closed. And where do you suppose was opportunity? Just a few blocks to the south-east or, to be precise, where Berkeley street is lost in a maze of railroad tracks, the Joseph Simpson Sons, Ltd., Knitting Mills had to have a night engineer. Clark proved that he was competent.

That is 13 years ago, and for these last 11 years he has been, and is to-day, mechanical superintendent of the Simpson Mills. So if you are ever tempted to doubt the value of a good correspondence course in steam and electrical engineering or to underrate the practical help a man can get from such a paper as CANADIAN MACHINERY. go and talk with Hughie Clark.

In the big game named "getting ahead in the world" he has made a creditable score. I say that well knowing it is never wise to measure a man by the position he holds to-day. Rather stand in his shoes, if you can, and drop your plumb line to the job at which he started.

The Operators' Point of View

MAKING A RECORDING STEAM CONSUMPTION METER

By T. H. FENNER, Associate Editor.

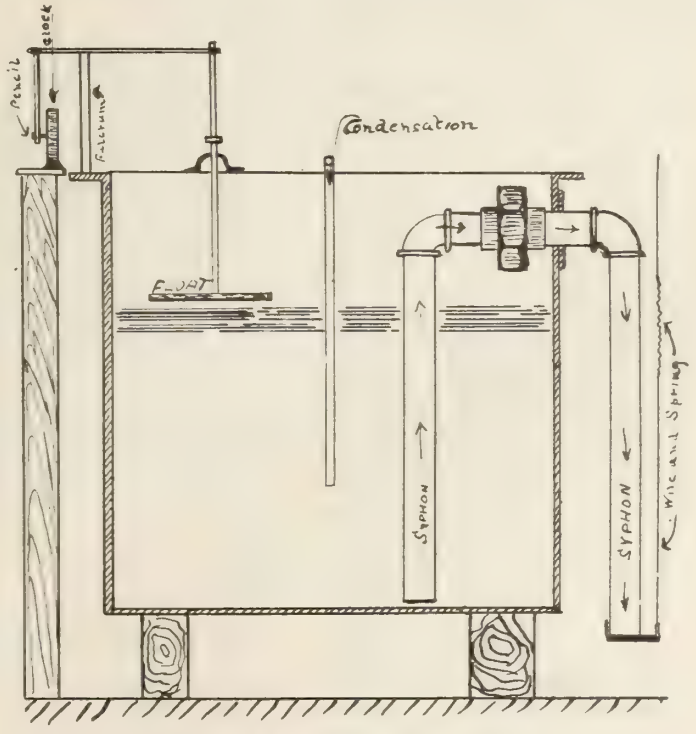
THE necessity often arises in plant and factory operation to determine the amount of steam consumed by a particular apparatus. This may be occasioned by the requirements of the cost accounting department, or by the desire to compare two different ways of operating the same unit, or the relative merits of two different appliances for the same purpose. For all these purposes, accuracy is the essence of the contract, while the question of obtaining accuracy with small expense is also important.

Methods of Measuring Water

If there are suitable tilting traps on the premises, to which a counter can be attached, registering the number of times the trap discharges in a certain time, then the volume of the trap being known fairly accurate results can be obtained. However, there is always room for inaccuracies to creep in, through leakage from glands, valves, etc. If all working parts are perfectly free to move, the trap will be sensitive, and open and shut promptly, while if the gland packings are at all hard, or unduly tight, the trap is slow to open and discharge and steam is blown through for a moment after the condensation has been removed. Errors like these are small in themselves, but multiplied by a large number of operations extending over days, they make a respectable total, and render valueless any test that does not take them into account. An ordinary water meter may be used, but these are by no means to be depended on. If a Venturi meter can be connected up to the return pipe, it is possibly the best means of securing the consumption, but a large number of plants do not possess these instruments, and where they are installed they are usually connected to the boiler feed, and are not easily moved.

Needed a Meter

The writer had occasion some time back to determine the steam consumption on a number of different kilns, used for baking Japan, varnish. etc., also lumber drying kilns. As the results were to establish the cost of production of various parts, accuracy was necessary, while at the same time it was not desired to go to much expense in securing the figures. Under these circumstances a search around the plant was made for suitable equipment. There were a variety of traps on the premises but none on which much dependence could be placed for a particular job of this kind, so they were eliminated from the list of possibilities. However, in looking around a store house of obsolete or unused machines, several steel tanks that had been used in the plating room, were discovered, and these suggested the idea of making our own measuring appliance, which was at once acted on, the result being a very serviceable instrument, at practically no cost.



HOME-MADE WATER METER

How It Was Made

The tank, as shown in the cut was mounted on skids, and kept about 18-inches off the floor. This was to give room for the discharge pipe to come below the bottom of the tank. The general arrangement can be followed easily by referring to the cut, and the action was as follows. The condensation was led into the tank from the kiln to be tested by a half-inch pipe. A 2-inch nipple with a long thread was screwed into the side of the tank near the top, and a union put on inside the tank, to connect the suction leg of the siphon pipe. The down leg of siphon was connected to nipple through the elbow outside the tank as shown ,and the pipe carried down low enough to give a good discharging head. On the end of the discharge pipe a clock valve was fastened by a hinge, and on the opposite side to the hinge a lug was carried out, to which was fastened a wire, the other end being fastened to a beam in the ceiling, and a light spring connected between. This valve and spring were the key to the whole affair, and some considerable experimenting had to be made before the correct strength of spring was arrived at. This spring had to have just enough tension to balance the column of water in the siphon pipe, so that the instant the water rose above the top of the pipe, the valve would open. This would start the siphon, and the velocity of the escaping water held the valve open till the water was emptied down

eo the level of the bottom of suction pipe. The spring would then close the valve, and the tank fill again. Here then, we had a definite quantity of water discharged, and all that was wanted was a means of recording the number of times the tank was filled and discharged in a definite period, and make one necessary correction. This correction was the quantity of water flowing into the tank from the return pipe while the siphon was discharging. This was merely a matter of placing a T on the return pipe, with a valve outside the tank. A pail was placed under this, and the tank watched carefully, and as soon as the siphon opened, the valve on the return pipe was opened and the water ran out into the pail instead of the tank. As soon as the tank was emptied, the valve was closed and the water in the pail weighed carefully. This weight had to be added to the weight of water discharging from the tank, to make it correct.

The Recording Chart

For recording the number of times discharged, a chart, registering automatically was required. This was secured by purchasing for 75 cents an ordinary domestic alarm clock. The fingers and dial were removed, and a tin dial soldered onto the spindle of the hour hand. Four small cleats were made on the new dial to hold a paper chart. A flat piece of wood, 1-inch thick by 6-inch. square formed a float into which was fastened a piece of ¼-inch round iron, which passed through a guide fixed on the flanged edge of the tank. A cross beam of wood was connected to the top end of this and this was supported on a fulcrum about two-thirds of its length away from the float rod. The other end carried a vertical rod, through which was passed the pencil. A stop was placed on the float rod, to hold the float up when the water dropped below a certain level. This level was adjusted to give just enough upward travel to the float when tank was filling, to make a mark of 1½-inch. long on the chart. The charts were placed on the dial at 7.00 a.m. and 7.00 p.m. and thus a continuous 12 hours record appeared on each chart. The position of the clock is shown on drawing. In the actual layout the clock was enclosed in a wooden box, to protect it from steam, and dirt in the air. The valve on the bottom of siphon pipe was made of two pieces of galvanized iron No. 16 gauge, one soldered to the other. The top piece was of just sufficient diameter to enter the pipe neatly, while the bottom piece was made to the outside diameter of the pipe, and two lugs made on it, one for the hinge the other for the wire. A piece of good 1-16 wire wove insertion was made to fit the end of the pipe, to form a joint, and fastened onto the valve to begin with by shellac. Otherwise, the rush of the water would have washed it off. Later on this insertion joint was replaced by a ring of square rubber, ¼-inch wide by ⅛-inch thick. This was more satisfactory. Later on two more tanks and clocks were added, to enable three different tests to be made at once. This method resulted in accurate figures being furnished, and the only new material was the three clocks costing $2.25. The pipe and fittings were all on hand, and the labor amounted to probably another $2.

EMERGENCY PIPE REPAIRS

By James E. Noble

While employed as engineer at the Hospital for Insane, Toronto, I made numerous repairs in what might be called, "hurry-up jobs," a description of some of them might interest your readers. Fig. 1 shows a cast iron water pipe which was broken in two as a A, caused by the building foundation sinking. Some of the stones were removed from around the pipe and a clamp made 6 inches wide and ¼ inch thick as shown in Figs. 1 and 2; sheet rubber was placed around the pipe over the break and pieces of sheet copper were used at DD, Fig. 2, where the ends of the clamp came together and all the bolts tightened up, this job was done about ten years ago, and so far as I know is still in use. To my own knowledge it was still in use about two years ago.

Fig. 3 shows a 6 in. cast iron pipe at the same institution. A two-inch pipe was screwed into a hole which had been drilled in the pipe, probably a strain had been placed upon the two-inch pipe for a long crack developed in the 6-inch pipe. A piece of ¼-inch plate was heated and bent to form a fit over the 6-inch pipe, a half circle was cut from one end to fit over the 2-inch pipe, as at A, Fig. 4 a piece of ⅛-inch sheet rubber was placed over the hole with the bent iron on top of it and all drawn up in place with two clamps as shown in Fig. 4. This job also is in use after many years.

A 3-inch steam coupling started to leak at the threads caused by the ends becoming corroded. A piece of galvanized sheet iron was bent around the coupling to form a sleeve, the space between

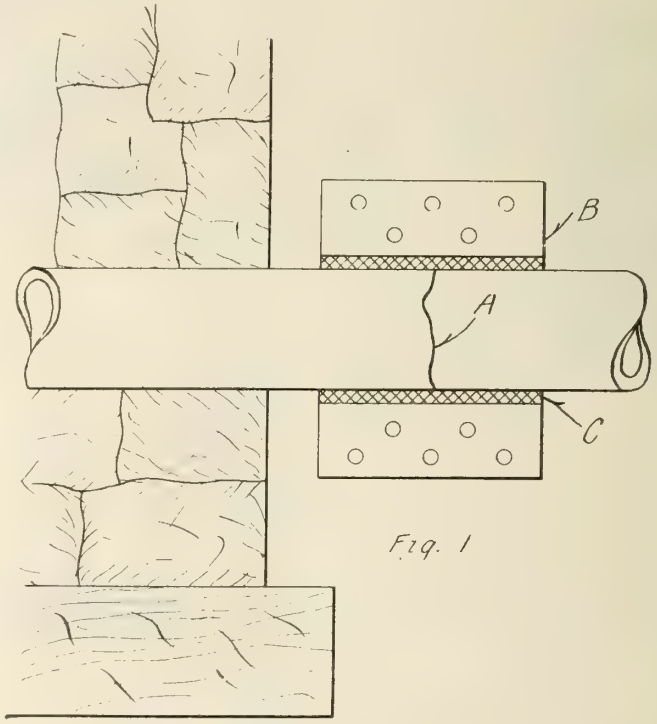


Fig. 1

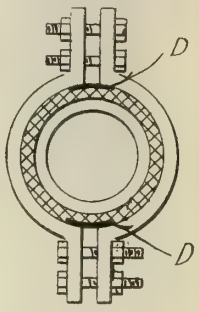

Fig. 2.

METHOD OF REPAIRING BROKEN MAIN

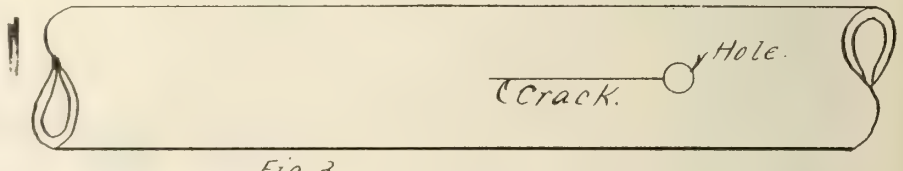

Fig 3.

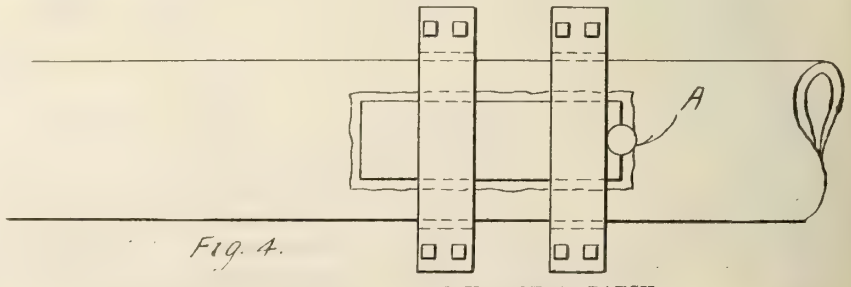

Fig. 4.

STOPPING CRACK AND THE USE OF A PATCH

the coupling and the sleeve was filled with elastic and dry smooth on cement mixed, heat was applied to it from a blow-torch for about half an hour, and in two hours steam was turned on and the leak was stopped.

While extending a water main in an outside town it developed that we were just 18 inches short. Instead of sending to the city for a pipe and sleeve we cut off a piece of larger pipe 24 inches long; this was slipped over the end of the pipe before making the lead joint at A, Fig. 6. Six turns of ordinary galvanized telephone wire were tightly drawn around the ends of the piece of large pipe and the joints packed and lead run in in the usual way, result being O. K.

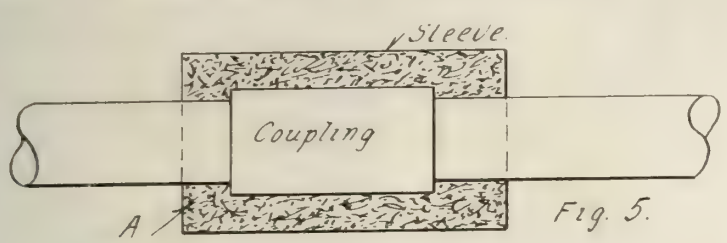

Fig. 5.

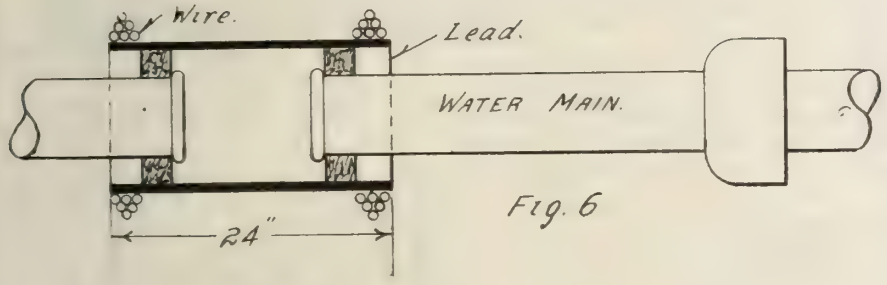

Fig. 6

WHAT IS AN ENGINEER

Being a subscriber to POWER HOUSE, a paper much appreciated by all operating engineers who handle it, I have been toiling around in large and small steam plants, fireman, oiler, and engineer, if it fits in to use the term. I have been approached by so-called union engineers with the question, "Are you making a living wage on an eight-hour day, or in other words, are you receiving sufficient wages per hour to allow you to live on an eight-hour day?" I know there are quite a few plants running on eight-hour shifts, but who are the engineers? It seems to me there is only one who is the chief, the rest are only handy helpers; and so we can go through Ontario, and but very few engineers are required, just one in each plant. Now I know there are plenty of good men in Toronto, good engineers, but are there positions for them? Experience tells me no, and I think quite a number of engineers will agree with me, as they have been placed in the same rut as myself in answering an advertisement for an engineer. The first question put to you is, "Have you got a certificate?" Naturally you have or you would not go after the job, and you say, yes. Then comes the conversation, "Well, you know we have no engine, just a motor and one, two, or three boilers just for heating the building; that doesn't need much of an engineer, so we expect you to give a hand at so and so in your spare time, and what is most important, having the buidling comfortable in the morning. Of course you must be on hand early every morning, but then you have it pretty easy all day up to 5.30 or 6 o'clock, when you will shut the plant down for the night, providing they don't work overtime. Oh yes, you must come down on Sundays and holidays! Saturday afternoons you have a good chance to do any boiler work or temporary repairs and be ready on Monday morning. The electrician will tell you he has charge of the building; that's the way us so-called engineers are up against it, at any rate I find it so after some forty years at the occupation. I ask, am I the engineer in charge or is the electrician? I am considered well paid with 18 or 20 dollars per week of about 70 or 80 hours. Of course you must keep all piping in repair and the boilers, ah yes, they must be O.K. when the inspector comes. In conclusion I would like to draw your attention to the advertisements coming out in the daily papers, quite a few of them for firemen to take charge of boiler or boilers, not a word about certificates at all.

Yours truly,
FRED. CLARKE.

CONVERTING A GROUCH

By J. James

A few days ago an engineer remarked to me, "These engineering journals make me weary." Said I, "What special ailment is bothering you now, my friend?" He elucidated somewhat as follows:

"The editors come at a fellow and call him down because he will not write about how he overcame some difficulty in connection with his work. They say, never mind if your sketch is crude and your letter shy on correct grammar, writing or spelling, we will polish them up for you, it is the idea we want, and we will cash up for that same idea, telling how you won out and so forth and so on. There am I taking their advice and using up my postage stamps, time and stationery to help them out, and every time my letters come back, not because they are not good enough, so reads their printed notice enclosed with the returned letter, but because they are not suitable for the journal. How do I know what will suit them? I send them power plant experiences all right, dang it all, my experiences are just as good as some of those I see in print, and better than a lot of them." At this point he paused, but before he got started on the second lap I cut in. "Will you allow me to throw some talk for awhile? I have written many hundreds of letters for these journals you talk about and have received cash for many of them; I have also had many of them returned as being unsuitable, perhaps the ideas therein were old and had been printed several times without my knowledge, in fact on two occasions when I thought I had solved some particularly difficult problem the editor made a note directing my attention to where practically the same idea had been printed many moons before I had sent in my MSS.

"Another way to look at things is this: The editor is the buyer for the publisher; he is paid for what he knows about goods that will give satisfaction to the publishers' customers; these are the subscribers as a whole, he is responsible for the material dished out in the editorial or reading pages. He does not want to tell a customer, who is trying to sell him some stale goods that the said goods are out of date, he just sends on a polite printed note letting him down easy, and perhaps the note contains a carefully hinted suggestion to try and bunco some other editor who may prove an easy mark." At this point I started talking again before my friend could do so.

"Suppose a traveling salesman for some goods of which you had a big stock on hand, called on you and insisted you buy more of the goods just because they were good, the fact that you did not want any more of them making no difference to him, what would you do, would you give in to him and buy something you did not want with your nice handy cash just because he thought he knew your business better than you did yourself?

"Perhaps you are in the same class, trying to sell something the editor has enough of or has had enough of. Try again, perhaps your next near original idea will catch him unprepared, and he may cause your chest to swell and your heart to throb when you receive his check for a whole lot of dollars, perhaps as many as two, but never forget he is the buyer and you the seller. If you cannot think up something original try and put a disguise on it and make it look original (this is my advice, not the editor's. I bet he won't print it), perhaps you may get by with it. An editor is only human—you may not believe this but it is true, so if you stick to it long

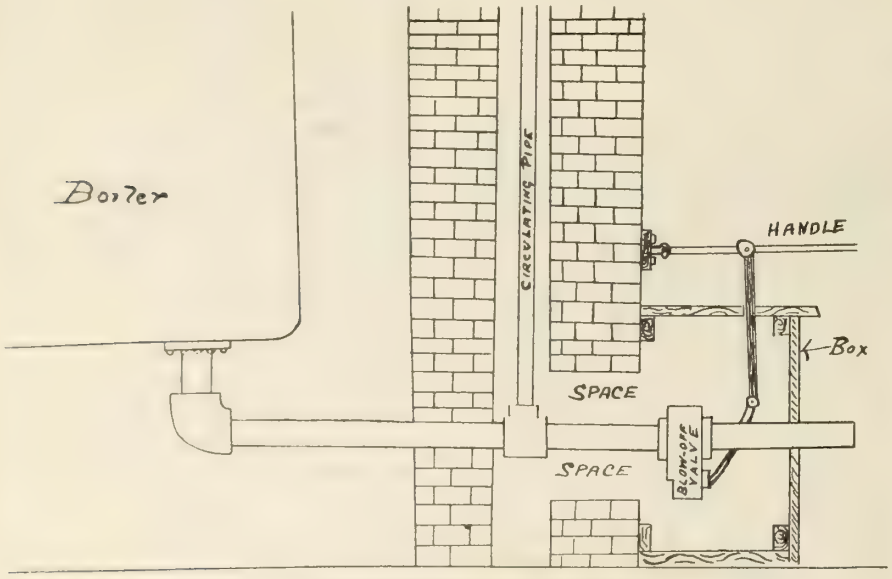
enough you are bound to get him some day and receive enough coin to pay for all the stamps and stationery you have used up in the past."

"Dang it," said my friend. "I thought I could talk, you are it, take some advice from me, quit engineering, go sell books, you will make a fortune. No one could choke you off. Say, I believe you have done me good, anyhow, I'll think better about those editor fellows, especially do I pity them if they have to watch out for fellows like you if you write as fast as you gas."

KEEPING BLOW-OFF FROM FREEZING

Restricted space was the reason for placing the steam boiler close to an outside wall. As the blow-off valve could not be run from the side wall for certain reasons it was connected as shown. This was all right during the summer but in the winter, with the temperature away down, things would freeze up. To prevent this happening a space six inches above and six inches below the pipe, that is a square hole eight inches in diameter was cut out of the brick wall at the pipe, and a wood box built around the blow-off valve outside. The box was made in sections so that it could be taken apart to make repairs to the valve or rods. The valve was opened or closed by raising or lowering the handle. The valve did not freeze up because enough heat from the boiler room came through the 8-inch hole to prevent this.

JAMES E. NOBLE,
Portsmouth, Ont.



ARRANGEMENT OF BLOW-OFF

THE CARE OF SCALES

By W. Schaphorst

Engineers and others in and about the plant often use scales in various ways without giving them much thought. It is generally assumed by the average engineer that if a scale "balances" before the load is put on, the weight registered will be "accurate," but such is not always the case. Much depends upon the care given the scale between weighings. It might, therefore, be a good plan to say a few words about scales in these columns for a change.

In Figure 1 is shown a so-called

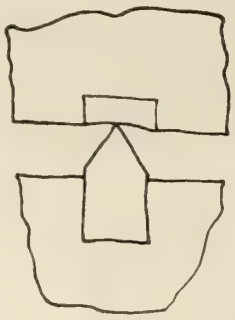


FIG. 1

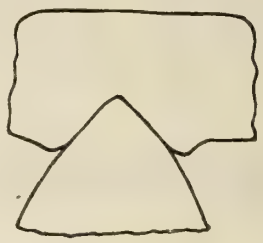

FIG. 2

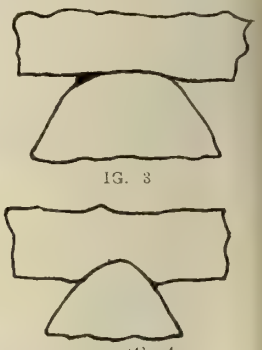

FIG. 3

FIG. 4

"knife-edge." On top of the knife-edge is the bearing. Both the bearing and knife-edge should be made of the same material, of equal hardness. The harder and stronger the material used the better, in most cases.

However, it is evident that we must have more than mere "line contact" when there is any sort of load on the scales. The knife-edge on a jeweler's scale may be so sharp that one could shave with it, but on the high capacity scales the knife-edge is really nothing more than a blunt edge, and in the largest scales is actually a flat surface without semblance of a point or "edge." Yet, they are "called" knife-edges, although the proper word would be "pivots."

Figure 2 is an imagined enlargement of what occurs where the knife-edge is harder than the bearing. It is evident that the principal deformation will take place in the softer metal.

Figure 3 shows a case where the knife-edge is soft and the bearing is hard. The knife-edge, of course, will be "blunted down" pretty much as shown.

Figure 4 shows a case where both metals are of the same hardness. That is the "ideal" case, although it would be much nicer if we could get away from surface contact altogether. Theoretically, the ideal case is a "line" pure and simple. If the line could be attained in actual practice things would be simplified very much for the designers of scales.

To keep a pair of scales in good condition it is, therefore, important that they be never overloaded. Overloading may deform the knife-edges of bearings permanently. Never allow a weight to drop heavily upon the scale platform, for blows are liable to deform the edges, too. And never allow a heavy weight to remain long upon the platform. Give the knife-edges an opportunity to return to their normal shape as soon as possible after the weighing. A long-sustained heavy load will cause the knife-edges to "flow" and remain deformed permanently.

To date, the best metal for knife-edges for use on high capacity scales is the high-speed steel that is used so much in machine tool work. A new metal called stellite, however, has lately been put on the market as superior to high-speed steel. It is exceedingly hard and will scratch the hardest hardened steel. There is no iron in stellite at all except as an impurity. Stellite is very likely the coming metal for knife-edges. It has another advantage over steel in that it does not corrode.

HOW MUCH HEAT IS LOST?

By W. F. SCHAPHORST.

How much heat is lost in allowing a boiler to cool off for cleaning and in starting it up again? There is a question that will cause many an engineer to stumble. It is much like the time-worn conundrum, "Which came first, the egg or the hen?" When a boiler cools off the heat is being dissipated into the air, true enough. And when the boiler and setting are being reheated, the heat out of the coal is all being apparently wasted. None of it is converted into work. The amount of heat lost on cooling is equal to the amount required to heat it all equally again, but the actual loss is "only one of them." Don't add them together. Or, add them and divide by two.

BOILER AND COMBUSTION APPLIANCES

The Defender Automatic Regulator Co. of St. Louis, Mo., manufacturers of automatic damper regulator, combustion appliances and instruments for the boiler room, moved to larger quarters on November 1, at 709 Pine street, and they have issued a new catalogue, No. 10, which shows some improved instruments and appliances, three of which we illustrate.

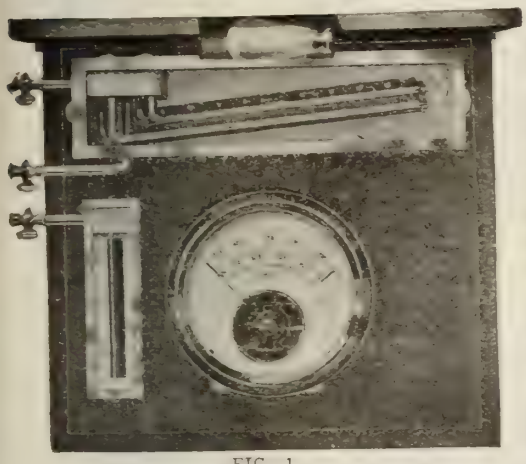

FIG. 1

Fig. 1 shows their control board for mounting on the front corner of a boiler; on same is mounted the Defender duplex draft gauge and flue gas pyrometer. As illustrated the board has a vertical gauge at the left to read the pressure in the blast below the grate on forced draft furnaces; for natural draft plants the board is furnished without the vertical gauge. The top hood, which has a shade for electric socket all cast in one piece, is attached on to the top of the cast back with a screw at each end, which allows the hood and light to be raised up when working on the instruments. When hood is in place it keeps the dust and water from falling on the gauges as well as illuminating the board; this is a big advantage in dark and dirty boiler rooms.

Fig. 2 illustrates the Defender cast iron gauge case for mounting on the boiler front. In same is encased their Duplex draft gauge and recording flue gas thermometer the same is furnished with any number of feet of bronze armor tubing, so that for water tube boilers the case can set on the front corner of the boiler where the firemen can see the instruments at all times.

Fig. 3 shows the cast iron case manufactured by this company for forced draft or under feed stokers. The three tube draft and pressure gauge is mounted in the bottom of the case. This gauge reads the pressure in the blast below the grate on the top tube, the draft over the fire on the centre tube, and the draft at the last pass of the boiler on the bottom tube. The difference between the reading on the centre and bottom tube being the drop in draft through the boiler, or what is commonly known as the differential through the boiler, this differential will increase and decrease as the boiler capacity increases and decreases. The flue gas pyrometer to read the temperature of the flue gas at the last pass of the boiler is mounted in the top of the case. The manufacturers claim that with a set of these instruments mounted on the front of each boiler and one of their cases for reading the per cent. of CO_2 in the flue gas, that the following indications and information are given to the operator at all times.

The exact conditions of the fuel bed at all times; fires too long or too thick; fires too short or too thin; too much or too little air; fires clinkered; when time to clean fires; percentage of excess air used; the total loss and avoidable loss of fuel on each boiler; the per cent. saving that can and should be made; if baffles are leaking; if soot is accumulating in boilers; when to use flue or soot blowers; how long to use them; if any good or any saving is made with the use of them; if one boiler is operating more efficiently or at greater capacity than others.

Fig. 4 shows the Defender case and single chamber orsat to read the per cent. of CO_2 at the last pass of the boilers. This is shown with four pipes from the last pass of four boilers run through the top of the case and the gas suction pump mounted on the outside of the case. With the use of this case piped up for the battery of boilers a sample of gas can be drawn from any of the boilers and an analysis made in less than one minute's time. After a few dozen readings for CO_2 have been taken on each boiler and the firemen once taught what the indications on the instruments are with the different percentages of CO_2, then the readings for the CO_2 do not have to be taken very often as the draft and flue gas temperature guides the fireman.

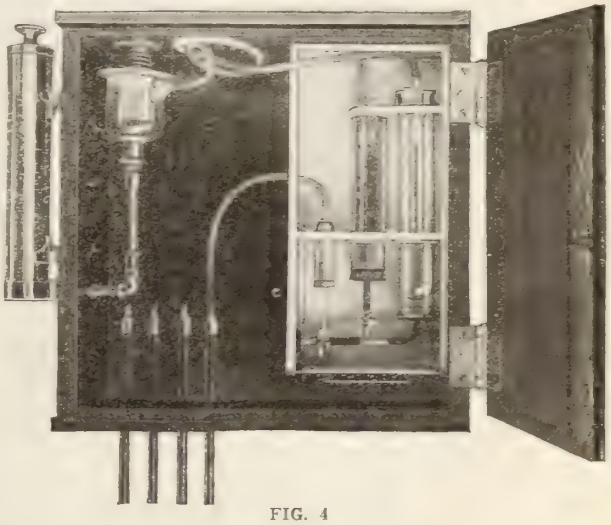

FIG. 4

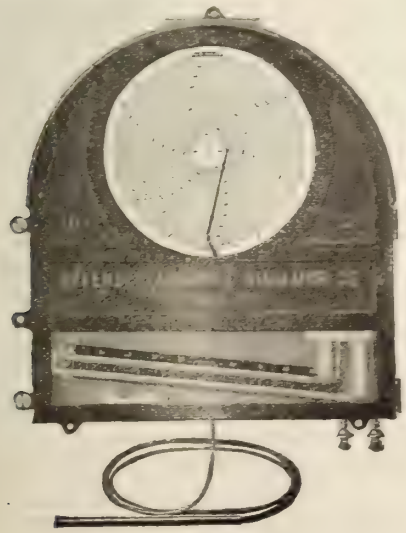

FIG. 2

FIG. 3

"The Heating of Houses, Coal and Electricity Compared" is the title of Bulletin No. 6 issued by the Honorary Advisory Council for Scientific and Industrial Research, Ottawa. This publication summarizes the advantages and disadvantages of both the methods of heating, and reduces their cost to an equal basis for a comparative purpose during the past few years and the fuel problem has become acute in Canada, and an idea appears to have been gaining ground that the immense water powers of this great country will amply suffice to meet all heating requirements. The climate of the greater part of Canada is so severe in the winter that even the immense potentialities of its water powers, if fully developed, would be altogether inadequate to cope with the demand for power for electric heating if this were increased to any great extent.

The advantages of electric heating and the difficulties preventing the adoption of electric heating on a large scale are dealt with, and the cost of heating a house electrically at a lowest domestic lighting rate is also given. This cost will be considerably lessened by the use of electricity supplied at power rates, but in this case even, it will not be possible to bring it within the cost of heating by coal.

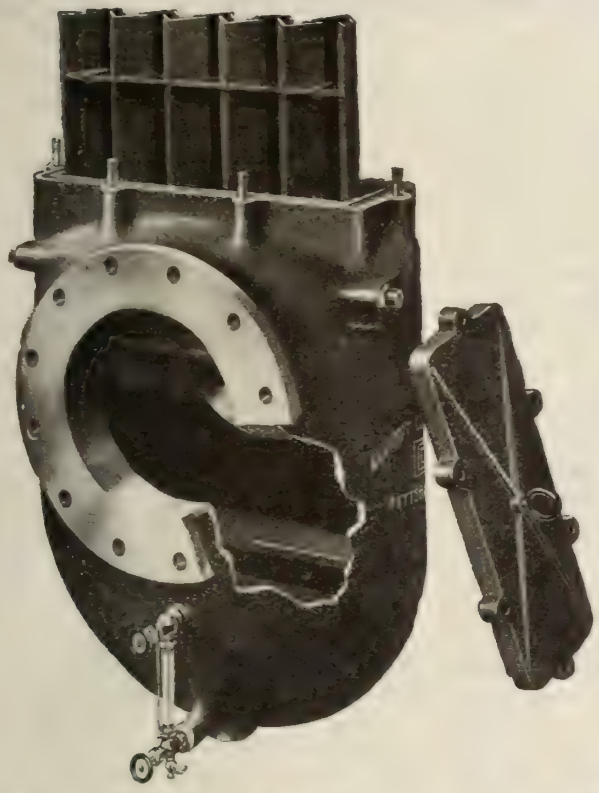
Here's an Oil Separator that took on a "side line"—



You've had a grease salesman pull a sample of packing from his pocket and try to sell you some.

The grease salesman was carrying a "side line."

Same thing with this Elliott Oil Separator. Its main job was to take oil out of steam—but it had a side line.

The engineer of the plant tells the story.

"Before we installed our

ELLIOTT OIL SEPARATOR

we could not keep scale down," he said. "There was so much grease in the condensate which we fed back to the boilers that it left an accumulation on the flues. The boiler compound couldn't get in its effect.

"I could run my hand along any tube and have it come off dripping with oil.

"But the Elliott Oil Separator stopped the trouble. We can now keep the boilers in first-class condition."

Ever think of an Oil Separator handling a side line like **that!**

Don't be surprised that the Elliott Oil Separator handles the job so well either—

The Elliott Separator throws the oil **out of the path** of the steam. No chance of its getting back in again.

Furthermore, baffles in the Elliott Oil Separator are removable. **Easy cleaning!**

Bulletin "E" tells all about Elliott Separators. Write for your copy

ELLIOTT COMPANY

435 Grant Street, Pittsburgh, Pa.

Association and Personal

W. A. Black has been appointed locomotive foreman for the C. P. R. at Farnham in place of D. W. Watson, transferred.

Effective this date, J. A. Tobin is appointed assistant superintendent, Trenton division, office, C.P.R., Trenton, vice T. H. Hamilton, transferred.

John S. MacLean, advertising manager of the Canadian General Electric Company and also of the Canadian Allis-Chalmers for the past five years, has resigned.

Morriss and Company of Chicago have recently placed an order with the Locomotive Pulverized Fuel Co., 30 Church street, New York for a complete "Lopulco" system for crushing, drying, pulverizing and burning coal at their plant at Oklahoma City. They expect to use native coals and to make use of Texas lignite. The power plant contains seven Edgemoor boilers, having a total of 3,100 horsepower, all of which are to be equipped.

STOKER MANUFACTURERS' ASSOCIATION

At a meeting in Cleveland on August 1, 1918, an association was formed of the stoker manufacturers of the United States. The principal reason for getting together was to place at the disposal of the government the entire facilities of the stoker industry to the end that everything possible might be done to help out in the national emergency. Even after the war, however, it is expected that great benefit will be obtained by the association members in the discussion of subjects of interest and value to the stoker industry; in the advancement and improvement of that industry; in the standardization of stoker manufacture and application, and in the promotion of a spirit of co-operation among its members for improved production and increased application of stokers. Practically all of the builders of mechanical stokers are included as charter members of the association.

At the first meeting the following officers and executive committee were elected: President, P. Albert Poppenhusen, Chicago, Ill.; vice-president, S. L. Nicholson, E. Pittsburg, Pa.; secretary-treasurer, Fred H. Daniels, Worcester, Mass.; William F. Sauter, Philadelphia, Pa.; W. H. Rea, Detroit, Mich.

The Stoker Manufacturers' Association has been informed that it has been formally elected to membership in the Chamber of Commerce of the United States. A national councillor will be appointed by the association to represent it in the National Chamber, and through this national councillor the association will have an opportunity of expressing itself on national questions under discussion by the federal authorities.

The association, through its War Service Committee, has tendered to the federal government the entire resources and service of its members, and the committee is working with the Fuel Administration and the War Industries Board for the conservation of fuel, labor and raw materials. The association is prepared to do any and everything which may be necessary to prove that American business is ready to back up the government until victory is assured.

Chemical Products Wanted. — The Canadian Trade Commissioner in Manchester has been approached by British firms, who wish to form connections with recently developed chemical industries in Canada with a view to importing chemicals formerly obtained from enemy countries. The export of millboard and wood pulp board to Great Britain is a branch capable of great development, in Mr. Ray's opinion.

Power released.—Owing to the destruction of the munition plants at Trenton last month, the Hydro-Electric Commission power supply from the Trent for Eastern Ontario has greatly improved, as 4,000 horsepower was released by the Trenton catastrophe. As the result of this the Kingston Utilities Commission, which was laying in coal owing to the threatened limited supply of electrical energy, now finds that it will have coal on its hands, but Kingston householders will benefit as the result.

Want Government Aid.—At a general meeting of the council of the Canadian Manufacturers' Association at Montreal, attended by many leading manufacturers from all over Canada, it was decided to ask the Dominion government to take active steps in the reconstruction work and to make a grant of not less than $1,000,000 a year for research work to find new outlets for Canadian trade. It was further decided to represent to the government that no increase in export trade would be possible unless sufficient vessels were provided to take care of such trade, and representations will be made to the government requesting that strong action be taken to aid in the construction of sufficient shipping so that Canada's foreign trade is taken care of. President W. J. Bullman, Winnipeg, was in the chair.

Munitions Workers.—According to information sent from a number of the cities of Ontario this week, the following figures give the number of people in each place and the number engaged in the production of munitions:

	Population	Munition Workers
Preston	5,200	150
Paris	4,600	425
St. Thomas	15,000	300
Lindsay	8,000	600
Stratford	17,000	75
Belleville	12,620	130
Kitchener	19,266	40
Oshawa	8,240	125
Hamilton	104,491	10,000
London	60,000	500
Galt	12,000	1,200
Brantford	30,000	800
Guelph	18,000	1,000
St. Catharines	20,000	3,000
Welland	8,000	650
Owen Sound	12,612	100
Ottawa	100,500	360
Sarnia	12,000	310
Woodstock	11,000	140
Windsor	27,500	1,566

Hamilton Short of Gas. The gas shortage in Hamilton during the coming winter will be just as acute as it was last year. This was stated by E. S. Estlin, gas commissioner for Ontario, who was making an investigation for the Ontario Railway Board. Mr. Estlin urged that all citizens be asked to conserve gas to the greatest possible extent. He contended that those using it in furnaces were the worst offenders and would have to realize that conservation was absolutely essential. Mr. Estlin has made a survey of the number of industrial plants and business places using gas from the Selkirk fields and he found that there were 60. These had not yet been put on permits but this step would be taken at once, he stated. There are 150 applications for gas now on file at the office of the United Gas and Fuel Company, Hamilton. New consumers will not be taken on. Mr. Estlin instructed Mr. Byrnes that under no consideration would more consumers be added.

SPOT WELDED BRAKE HANGERS

The Portland Railway, Light and Power Co. finds that the half-ball brake hangers used on its Brill trucks can be repaired by spot welding. The repair costs less than a new part (besides eliminating delivery delays), and the repaired parts have longer life than the new equipment. The worn parts are sorted according to their condition and repaired to fit corresponding gauges.—"Electric Railway Journal."

Don't
Let Clinkers Freeze to the Sidewalls!

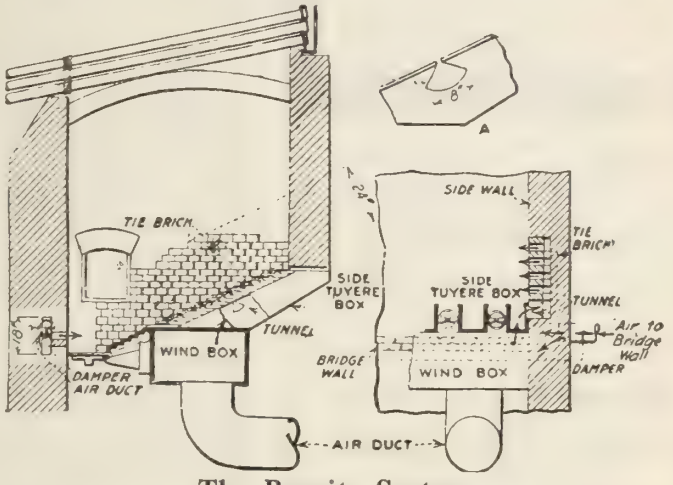
Wherever intense fires are maintained the coal will naturally slag down into clinkers. The clinkers will adhere to the sides of the furnace walls, and, fusing with the brick in large masses, extend over the grate and prevent the proper combustion of the adjacent coal. To break out such clinkers usually requires the dumping of the fire, and the use of heavy sledge-hammers and slice-bars, with the consequent damage to the side-walls.

The Bernitz Method Prevents It!

by arranging the bricks in the sidewalls and bridge walls in such a way as to allow a current of air to play around the bricks where they come into contact with the fire-bed, and by thus keeping them below the fusing point, prevent the clinkers "freezing" to the walls.

What is the Bernitz Method?

The Bernitz Method is a method of furnace wall construction of fire brick, having an air passageway inclosed in said wall, immediately back of the face brick, forming the furnace face which is directly in contact with the fuel in the furnace, and air passages opening from said inclosed passageway through the furnace face into the fuel, whereby a constant supply of air around the face brick in contact with the fuel bed, is provided.



The Bernitz System as applied to a Taylor Stoker Installation

The Bernitz Invention is Licensed, Not Sold

The Bernitz Method has received full patent protection in Canada and the United States and foreign countries, and licenses, under its patents, both issued and allowed, are now being granted on the basis of the H. P. rating of the boilers under which the Method is installed. Several installations in Canada.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 TO 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

CATALOGUES

The saving of a piece of coal the size of an ordinary egg on each scoopful of coal used in locomotives would amount to 1,500,000 tons a year. Even when firing a freight locomotive on a heavy grade, one less scoopful of coal every fifteen minutes, or one less scoopful every three or four miles, would effect a similar saving. A little more personal interest on the part of railway officials and employees will reduce coal consumption even on railroads where the practice is already excellent and where an earnest effort is being expended to save coal. A study of the practice in the use of fuel on the railways, however, discloses many means of effecting even greater economy.

The Engineering Experiment Station of the University of Illinois has issued a circular, the title of which is "The Economical Use of Coal in Railway Locomotives," to present some suggestions concerning ways in which large coal savings may be made. The circular is printed in four colors.

The facts presented in this circular have been compiled by a special committee of the research staff of the Engineering Experiment Station, assisted by an advisory committee consisting of E. W. Pratt, Assistant Superintendent of Motive Power, Chicago and North-Western Railway Company, Chicago; W. L. Robinson, Fuel Supervisor, Baltimore and Ohio Railroad Company, Baltimore, Md.; A. N. Wilsie, Chairman, Fuel Committee, Chicago, Burlington and Quincy Railroad Company, Chicago; Timothy Shea, Acting President, Brotherhood of Locomotive Firemen and Enginemen, Cleveland, O.; A. B. Garrtson, President, Order of Railway Conductors of America, Cedar Rapids, Ia.; W. S. Stone, Grand Chief, Brotherhood of Locomotive Engineers, Cleveland, O.; O. P. Hood, Chief Mechanical Engineer on Fuel Conservation, U. S. Fuel Administration, Washington, D.C., and C. F. Richards, Dean of the College of Engineering and Director of the Enginering Experiment Station, University of Illinois.

Copies of this circular may be had by addressing the Engineering Experiment Station, Urbana, Illinois. The price is twenty cents.

"The Fusibility of Coal Ash and the Determination of the Softening Temperature" is the title of Bulletin 129, just issued by the Bureau of Mines, Department of the Interior.

In describing the purposes and scope of the investigations, the authors, A. C. Fieldner, Albert E. Hall, and A. L. Feild, say:

"As a safeguard against excessive clinker troubles, specifications for the purchase of coal can be drawn to include the 'softening' or 'fusing' temperature of the ash. The value of such information has been recognized by the Bureau of Mines and has induced the bureau to investigate laboratory methods of determining the fusibility of coal ash, and the bearing of the results on clinker formation in fuel beds. The bureau realized that the fusibility of a mixture of oxides and silicates such as is comprised in coal ash varies according to the conditions under which tests are made, and that in the absence of any generally accepted method, no agreement is to be expected among tests made in different laboratories. Indeed, L. S. Marks has recently called attention to differences as great as 390° C. that were obtained with the same sample of ash by two different laboratories. Therefore if a fusion-temperature clause is to have any place in specifications for coal, a standard method of testing should be adopted in order to insure comparable results by different laboratories and to obtain the softening or fusing temperature of the ash under conditions similar to those of a fuel bed. After a consistent method has been devised for obtaining comparable results at different laboratories there will remain the correlation of these results with those from the burning of coal in furnaces before the value of fusibility tests in coal specifications can finally be determined.

"The present publication reviews the literature on the subject and gives in detail the effect of various oxidizing, reducing and neutral atmospheres such as are found in various parts of the fuel bed on the softening temperature of ash when molded in the form of Seger cones. As a result of this study a practical method of determining fusibility has been developed whereby the ash is caused to soften and form slags in which the iron exists in approximately the same state of oxidation as the iron in fuel-bed clinkers.

"Although it is believed that this method will indicate the probable clinkering characteristics of a coal better than any fusion tests heretofore described, the bureau does not recommend the general use of this method in coal specifications until it is justified by actual trial in furnace tests of different coals. As no fusibility test of a well-mixed sample of the average ash of a coal takes into account the physical distribution of the impurities in the coal as burned, much additional investigation is needed to establish the exact relation of these laboratory fusibility tests to clinker formation. In order to correlate this proposed test of minimum softening temperature with clinker formation, the bureau is now making clinkering tests in a specially designed experimental furnace, in which different coals, having ashes that differ in fusibility are burned under similar and known conditions of combustion. The results of this investigation will be published in a subsequent report. In the meantime it is hoped that other investigators will obtain similar correlation data."

Copies of this bulletin may be obtained free of charge by addressing the Director of the Bureau of Mines, Washington, D. C.

STANDARD SPECIFICATIONS FOR BABBITT METALS

THE American Society for Testing Materials, at its annual meeting at Atlantic City, N.J., June 25-28, 1918, proposed the following specifications for babbitt-bearing metals, designated as grades Nos. 1 to 12:

TABLE NO. 1—FORMULAS.

	Copper Per Cent.	Tin Per Cent.	Antimony Per Cent.	Lead Per Cent.
No. 1	4.5	91.0	4.5	....
No. 2	3.5	89.0	7.5	....
No. 3	8.33 1/3	83.33 1 3	8.33 1 3	....
No. 4	3.0	75.0	12.0	10.0
No. 5	2.0	65.0	15.0	18.0
No. 6	1.5	20.0	15.0	63.5
No. 7	...	10.0	15.0	75.0
No. 8	...	5.0	15.0	80.0
No. 9	...	5.0	10.0	85.0
No. 10	...	2.0	15.0	83.0
No. 11	...	....	15.0	85.0
No. 12	...	....	10.0	90.0

TABLE NO. 2—PHYSICAL PROPERTIES OF METALS.

	Deformation of Cylinder 1¼" diameter, 2½" high at 70° Fah. in			Melting Point. Degrees.	
	At 1,000 lbs.	At 5,000 lbs.	At 10,000 lbs	Fah.	Cent.
No. 1	0.0000	0.0010	0.0150	453.2	234
No. 2	0.0000	0.0015	0.0120	460.4	238
No. 3	0.0010	0.0045	0.0070	462.2	239
No. 4	0.0005	0.0025	0.0090	365.0	185
No. 5	0.0010	0.0030	0.0090	.....	...
No. 6	0.0015	0.0050	0.0180	.....	...
No. 7	0.0010	0.0050	0.0230	464.0	240
No. 8	0.0020	0.0090	0.0630	469.4	243
No. 9	0.0040	0.0120	0.0840	469.4	243
No. 10	0.0010	0.0100	0.1540	471.2	244
No. 11	0.0010	0.0100	0.1190	474.8	246
No. 12	0.0025	0.0170	0.2850	474.8	246

The society wisely refrained from recommending these formulas for any special purposes; confining themselves to the statement that "these specifications cover the range of alloys commercially used."

It is regretable that these tables do not also give the coefficients of friction as this information would have been perhaps the most useful aid in determining the relative values of these twelve bearing metals—especially if tests had been made with water lubrication. But the society has made a good start and doubtless they will give these frictional coefficients at some future time.

However, the data furnished in these tables is useful for purposes of comparison, and the object of this article is merely to point out certain facts in connection with these figures that may have escaped general notice.

Many users of babbitts, especially those required for heavy duty, are very careful to specify "copper-hardened" metals, and certain manufacturers of babbitts, knowing this pedilection, boost copper-hardened products. In this connection we call attention to formulas Nos. 3 and 8, given in above tables.

No. 3 is a tin base metal and contains 8 1-3 per cent. copper, the highest percentage of copper in any of these formulas. This composition, under 1,000 lbs. pressure per square inch, compressed to only 0.0010, or one one-hundredth of an inch, and its melting point is 462.2° Fahr.

No. 8 is a lead base metal, which contains no copper, under pressure of 1,000 lbs. per square inch, compressed to only 0.0020, or two one-hundredths of an inch, and its melting point is 469° Fahr.

The difference between these two alloys under 1,000 lbs. pressure per square inch is only one one-hundredth of an inch, which is in width about equal to a line made by the stroke of a hard lead pencil, and the same relative difference between these two metals is maintained at 5,000 lbs. pressure per square inch.

As to the melting point of these two alloys, the lead base metal has the better of it by about 7° Fahr.

When you consider that the tests shown in Table No. 2 were made by compressing a small cylindrical-shaped block, and that in actual use a babbitt metal would, in most cases, be supported by a backing and further bolstered by recesses, the difference in sustaining powers between a tin base copper hardened metal and a lead base metal is practically nil.

Table No. 2 also gives a good illustration of the influence of lead in tin alloys, as shown by No. 4. This composition contains but 10 per cent. lead, yet this small quantity was enough to reduce the melting point to 365° Fahr., which is about 5° lower than the fusibility of half and half solder.

Attention is also called to the fact that the compressive strength of Nos. 10 and 11, which contain neither tin nor copper, is equal to that of No. 3 at 1,000 lbs. pressure per square inch, but at the higher pressure the No. 3 shows greater sustaining strength, due doubtless to its greater malleability, but such high pressures are rarely, if ever, used in actual practice. It is rather anomalous that alloys Nos. 1 and 2, which contain less copper and antimony than No. 3, should show greater resistance to pressure.

The conclusion that can be drawn from

The LONG Patent Steam Trap

Automatically drains jacket kettles, separators and steam mains. Nine hundred to 1,500 feet of one-inch pipe isn't beyond its ability. Also used with splendid success in drying room systems.

Only One Movable Part

Works against 1 and 200 pounds of pressure—no possibility of freezing. Has **two outlets** so it can be installed in any position.

Circular gives full particulars.

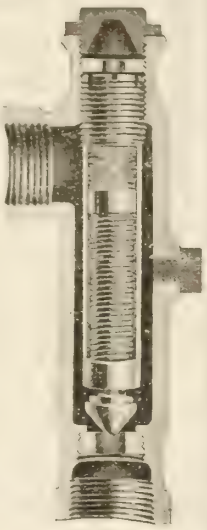
There is
Nothing Complicated
about the
Steam Trap
SARCO



It is just a plain steam trap which can be put straight on to the line like an elbow and without foundation or building up.

It traps the steam and releases the condensation.

It does not need to store the condensation as a bucket or float trap does, and because it needs no bucket or tank it is much cheaper.

It saves first cost.

It saves installation and repair cost.

It saves valuable space—and

It does save steam.

There is no other expansion trap operating on the same principle, and that the principle is right is proved by the fact that upwards of a million steam traps of this type have been supplied in the eight years it has been on the market.

the foregoing figures is very favorable to the use of lead base alloys for all bearing purposes except in cases where malleability is a prime requisite and paramount to all other considerations on certain forms of thin, loose shell bearings.

The lead base metal is unquestionably superior anti-frictionally to the tin base metals and by reason of that quality it wears longer, runs cooler and protects the bearing from the injurious effect of frictional heat, and it is very much cheaper.

The lead base metal also has an advantage in pouring as the tin base metal with high copper content has to be brought to a much higher heat to obtain the proper fluidity to obtain a good casting.

These figures of tests are doubtless dependable, and assuming that they are at least approximately correct, they unquestionably show the fallacy of using the copper-hardened tin base metals merely to obtain compressive strength and apparently authorities in these matters have been taking a good many things for granted.

The fact that lead base metals are being used successfully under extremely high pressures is evidence that their failure in some instances where the tin base metals succeed is doubtless oftentimes due to improper handling rather than fault of the metal.

THE DEVELOPMENT OF NITROGEN FIXATION IN AMERICA

In a lecture on the nitrogen problem, by Professor A. A. Noyes, at Washington recently, the author said that as regards "fixation" processes, America is now working, to a greater or less extent, all the methods which have been developed during the past fifteen years. Even before the war the American Cyanamide Company at Niagara Falls was producing about 20,000 tons of cyanamide a year, largely for use in agriculture. By the action of steam upon this substance it is practicable to get substantially all the original nitrogen in the form of ammonia. This process is capable of a great extension, and has already reached considerable proportions in Germany, where it competes with the Haber process. The American government is building a cyanamide plane with a capacity of 110,000 tons of ammonium nitrate at Muscle Shoals, Alabama, and a third plant has been authorized for the production of another 110,000 tons in Ohio. The cyanamide process has the advantage that it can be installed in many places in the country, and that it requires little power. It has probably a great future before it—certainly immediately—but whether it is ultimately destined to be supplanted by the synthetic process time alone can show.

SLIPPING OF BELTS

By M. E.

Belts, when running slowly and transmitting little power, may run a considerable time without giving evidence of slip, but when running at recognized speeds for the transmission of power, the slip may be considerable, although it is hardly a subject for calculation. Many factors may enter into the causes of slipping, slackness being the most important. Slipping, once begun, may polish the inner side of the belt and reduce its adhesion. A layer of air is said to enter between a high-speed belt and its pulley, serving as a lubricant and reducing adhesion. As a remedy, perforating the pulley with holes has been tried, but without definite results. Centrifugal action has also been suggested as a cause for slipping; but, when reduced to calculation, the centrifugal of a piece of belt x weight running at w speed round a pulley by radius would be a very small amount compared with the united pull of the driving and returning sides of the belt. There is another consideration, usually neglected, that may account for what might be called the permanent slip of all belts that are to any degree elastic. The driving and return sides of a belt work under different stresses, and as it passes from driving tension to return tension it is altering in length to the measure of its elasticity. When entering on the driven pulley it travels partly round before meeting the pull of the driving side, which takes place before it reaches the point of release. It is here that the belt is stretched and the permanent slip or creep takes place, which, in every elastic belt, is unavoidable. A properly adjusted steel belt should be free from this peculiarity and should ensure an accurate transmission of speed in all machines except those in which the respective revolutions of axis bring about fixed recurrent relations as in clockwork. Irregularities of belt transmission arise from dirt adhering to the pulleys or to the belts, and also from the action of heat and moisture. All belts and cords contain some moisture, and any increase or decrease of this moisture affects their length. A leather belt shortens on drying and elongates on becoming wet. Hair has the same property as leather, and this property is utilized in the hair hygrometer for measuring atmospheric humidity. Cotton cords and belts, on the contrary, shrink when moistened and elongate when dry.

DART

Union Pipe Couplings

Positively

No Leaks. No Upkeep Cost. No Replacement Cost.

Couple up the pipe lines with Dart Unions and you will be forever free from leaking connections.

Dart Union Pipe Couplings stay tight because the Bronze faces will not rust or corrode, and the heavy iron parts will not stretch or pull apart.

Dart Unions are easy to use because of the Ball-Shaped joint which enables you to connect pipes quickly, whether pipes are in or out of alignment.

ORDER FROM YOUR JOBBER.

He has them in all convenient types.

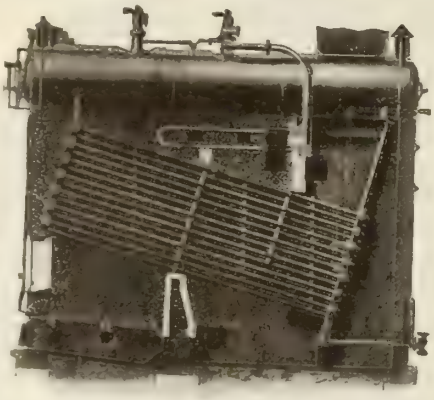
Betson's Plastic Fire Brick Lining, including fire box, front wall and arch, furnace side walls, bridge wall, combustion chamber walls and rear arch.

Your Own Men Can Put In A Betson's Plastic Fire Brick Furnace Lining



Betson's Plastic Fire Brick as used for B & W setting, including side and front walls, bridge wall and vertical baffles.

No need to wait for expert masons, or for shipment of special fire bricks or blocks.

Betson's Plastic Fire Brick replaces ordinary fire brick in about the same thickness and is adapted for lining any kind of boiler setting, including front and side walls, door arches, combustion chambers, rear arches, in any bridge and wing walls, baffles, etc. It comes in a plastic condition, is placed in chunks, consolidated with a mallet and smoothed with a trowel. No special forms are necessary, except of simple sheet iron to support door arches and light boards and braces for overhanging arches and walls. During the four or five hours of light firing required to dry and set the material these wooden supports are burned out, and the setting can then be put into full service immediately.

Betson's forms a one-piece lining without joints or cracks. Is perfectly gas-tight and much more durable than separate blocks or bricks. Betson's Plastic Fire Brick is shipped at once from stock carried in the following cities:

New York, Chicago, Philadelphia, Detroit, Cincinnati. St. Louis, Providence, Kansas City, Denver, New Orleans, San Francisco, Toronto, etc.

Ask for booklet "How Anyone Can Form a One-Piece Boiler Furnace Lining from Betson's Plastic Fire Brick."

Rub-Steel Valves

"THE VALVE WITH A BACKBONE"

WHAT IS IT? The RUB-STEEL VALVE is a valve made by a combination of rubber and steel.

THE CONSTRUCTION The construction consists of a plate of high grade steel placed in the centre of the valve with a specially tough and lasting rubber composition on each side and edge, attached securely and lastingly to the metal by the Elchemo process, which chemically unites the rubber and steel.

THE PURPOSE The steel plate gives such strength to the valve that the highest pressure cannot warp, twist or in any way get it out of shape, while the rubber surfaces afford the proper seating qualities. **"Better than Metal Because of the Rubber—Better than Rubber because of the Metal."**

WHAT IT ACCOMPLISHES It gives the valve a rigidity of form. It keeps the surface of the valve in its normal true position and insures a better seating quality. It prevents the high pressure from forcing the valve through the grating. It prevents the rubber from breaking up and the pieces causing trouble. It holds the surface of the valve in shape, so that when one side becomes worn the valve can be reversed without dressing. It is thinner and therefore gives greater efficiency to the pump. It permits the use of a softer valve for hot water, thus securing a better seat on worn or uneven "grids." It ensures an even distribution of the pressure, preventing "dishing" and the consequent cutting of the valve.

WHY YOU WANT IT **Because** its ultimate cost is less than that of ordinary type valves. **Because** it will last longer than other valves. **Because** it saves time and annoyance of replacement. **Because** its construction at once appeals to you as practical and sensible.

METLSKIN does prevent scale

Send for this illustrated booklet. It explains the dose, the method of action, and other important details

Some of Canada's and the United States' biggest and most representative plants have learned the truth of the above statement from first-hand experience.

So many "compounds" and "cure-alls" have been foisted upon unwary power-plant owners that the feeling, common to many of them, is one of doubt, of skepticism. And small wonder!

METLSKIN is not a "compound," nor does it work on the same principle. It is a boiler metal treatment, a boiler preservative that gradually removes scale by a safe process.

When the scale has been entirely removed METLSKIN forms a minute, grayish-white skin or covering over the bare metal.

So long as the daily dose is continued the scale-forming particles in the feed-water cannot adhere to the metal. Nor will METLSKIN work injury to any part of the boiler or system. That is one of the strongest features of the GUARANTEE BOND.

METLSKIN cannot contaminate the steam. It may be used safely in any plant where live steam comes in contact with the manufactured product.

If you are a skeptic, a doubter, ask for the booklet, GUARANTEE BOND, prices, etc. You will be interested, we know.

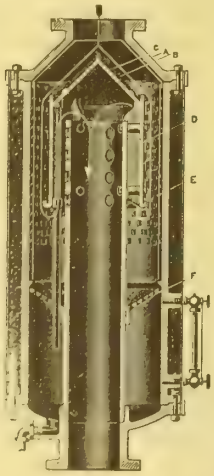
III IMPORTANT THINGS

TO CONSIDER ABOUT A SEPARATOR.



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

A Double Service Belt

The side of Spar Oak next the pulley is Spartan leather, giving the maximum grip on the pulley.

The outer part of Spar Oak is firm, heavy selected, special oak tanned center stock.

Most good belts are built so as to have either fine pulley-gripping surface and less ruggedness, or plenty of ruggedness and less traction.

Spar Oak, one of Graton & Knight Standardized Series Leather Belts, is a unique belt because it has super-gripping power and the firmness that resists the mauling of hard usage.

The side of Spar Oak next to the pulley is Graton & Knight Spartan—the belting leather with the highest co-efficient of friction ever attained in any belting material; the outside is the finest quality of Graton & Knight special oak tanned, extra firm center stock. Combined, they form a belt of absolutely unique quality.

Spar Oak Belting

Spar Oak stands high speeds without slipping or burning. It stays flat under strain. The punching of shifters and rapping of pulley flanges affect Spar Oak surprisingly little. Spar Oak belts in actual use carry their traction power up to speeds of more than a mile a minute. In the hard test of "mule spinning," Spar Oak has set new standards of what belting efficiency is.

If you have a vexatious belting problem, tell us about it and let us tell you whether or not Spar Oak is the belt required. There are thousands of cantankerous drives in the United States that will lose much of their crankiness when operated by Spar Oak. If you have such a one, it is well worth your while to write us about it.

More Power From Less Coal

If your line shafting is equipped with self-aligning ball bearings marked S K F, it is the most frictionless link in the route power must take from your coal pile to your machines. Such bearings reduce power losses 15 to 33%—lubrication expenses 60 to 80%, and eliminate hot boxes.

Ball bearings marked S K F, through their self-aligning feature and double row of balls, enable your plant to turn with the same power on less fuel. They abolish power waste. They save power. Power saved means fuel saved, and fuel costs money. For particulars send for Transmission Catalog and testimonial letters.

SKF

"The Power of the West"

AS soon as peace is in sight, politics will again come into play in Canada and then the West may hold the balance of power. Such is the prediction made by J. K. Munro, special political writer, in November MACLEAN'S. He thinks that the Western tail may wag the Canadian dog and that this explains why statesmen and others are trying to-day to get both hands on the tail. An outspoken article—incisive, humorous, fearless, unbiased. Read it—"The Power of the West."

Germany Should Pay Canada's War Debt

Had Germany won the Junkers intended to seize and divide Canada. Writing in the November issue of MACLEAN'S MAGAZINE, Lieut-Col. J. B. Maclean contends that the war debt we have piled up should be paid in cash by Germany as one of the terms. He makes a vigorous presentation of Canada's case.

Chronicles of the Klondyke

The real story of the great gold boom is being told for the first time by E. Ward Smith, who was treasurer, assessor, clerk and tax collector of Dawson City during the Yukon stampede. His series starts with "My Recollections of Early Strikes"—Strange stories of how men stumbled on tremendous fortunes in the frozen North. The author knew everyone in the Klondyke and saw everything that went on at first hand.

Bright Stories—Vital Articles—Famous Writers

The important articles and the big stories that are being written in Canada by the best Canadian writers are always found nowadays in MACLEAN'S. Here's a partial list of the November bill:—

The Minx Goes to the Front — **C. N. and A. M. Williamson**

Better Dead—The Silly World of the Spiritualists — **Stephen Leacock**

The Strange Adventure of the Staring Canvas — **Arthur Stringer**

Family Pride - **Theodore Goodridge Roberts**

The Three Sapphires - - **W. A. Fraser**

The Life of Mary Pickford - **Arthur Stringer**

We Must Tighten Our Belts - **Henry B. Thomson (Chairman, Canada Food Board)**

Lenix Ballister—Detective - **A. P. McKishnie**

Business Outlook — **Investment Situation**

Women and Their Work — **Books of the Month**

World Happenings in a Nutshell.—"Review of Reviews Dept."

The periodicals of the world are searched to get the best articles on current events. For instance, November MACLEAN'S contains: The Starving of Lille, The True Story of the Jameson Raid, Germany's Fleet Will Come Out? Mysterious New City in France, The Woman Who Caused Russia's Defeat, Hypnotism Cures Shell Shock, How Turkey Planned to Butcher British, Queen Mary is Accomplished Letter Writer, Why Palestine Was Captured.

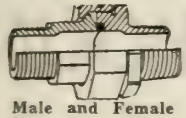
Jefferson Unions

Prevent Pipe Troubles In the Power House

The unprecedented demand for coal makes continuous productive operation more important now than ever. Time lost through shutdowns is "comfort to the enemy."

Jefferson Unions are built with the rugged strength which adapts them perfectly to the severe conditions of coal mining service. There are no "fads" on the Jefferson—they are the product of specialists whose sole purpose is to make unions—better unions—Jefferson Unions.

Be sure to get JEFFERSONS. Look for the name on the nut. It is your protection against costly shutdowns. The "just-as-good" union may look all right but you cannot afford to take chances where superstrength is required. **Ask your jobber to tell you all about Jeffersons. He knows their strong points and will be glad to help you select the right union for your job. Mail the coupon to-day.**



Male and Female Union, Style F, a short style which allows the use of any kind of a wrench.

Union Elbow. An economizer of the most pronounced type. Also made all female.

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction*. Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs*. Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

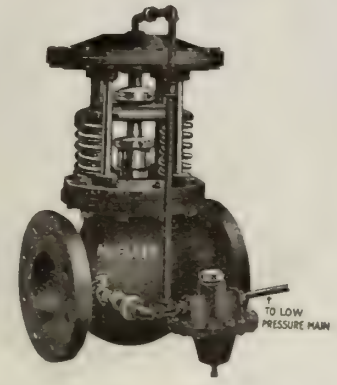
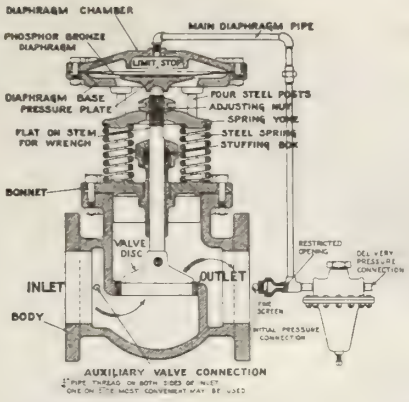
MONTREAL

MUELLER Reducing and Regulating Valve

SINGLE SEAT ; AUXILIARY OPERATED





E5030 for Water, Gas and Air
E5130 for Steam
(Flanged or Screwed.)

Very Popular with Shipbuilders

USES

This valve is for use on exacting installations. It will make any desired reduction and will maintain a constant delivery pressure regardless of fluctuations of the intial pressure.

CONSTRUCTION OF STOCK REGULATORS

All valves have iron bodies, bronze stem and stuffing box, phosphor bronze diaphragms, seats of composition suitable for the required service; iron diaphragm chamber and steel springs. The main valve is controlled entirely by the small auxiliary valve. This auxiliary valve closes and opens the main valve by admitting initial pressure to, and releasing it from, the diaphragm chamber of the main valve according to the demands of the delivery side. Regulators of this description are suited for pressures up to 150 pounds, and will be furnished at above prices. When regulators are required for pressures in excess of 150 pounds we will furnish of suitable material. Prices upon application.

STRAINER

In all cases it is advisable to use a strainer to prevent obstruction from grit, scale, cuttings, etc. Blow out pipes thoroughly before installing valve.

INFORMATION IN ORDERING

In ordering give highest and lowest initial pressure and required low or delivery pressure, approximate quantity or volume to be used per minute, size of high pressure pipe and low pressure pipe.

In ordering flanged end valves give diameter of flanges and bolt circles and the number and size of bolts.

INSTALLATION

Note.—Any proper working regulator acts as a check valve. Where the building up of the pressure is to be avoided use our diaphragm operated relief valve E5060.

We will not be responsible for improper selection of valves.
Consult us regarding the best type for your service.

The Guide to Better Valve Service

A TRADE-MARK means nothing unless it is backed by a good reputation.

For over fifty years thousands of plants and buildings have been using Jenkins Bros'. Valves. They know that the "Diamond" Trade-Mark is a guarantee of absolute dependable service.

Jenkins Bros'. Type "K" Brass Gate Valves are popular with Gate Valve users everywhere, and like others of the Jenkins Bros'. line, are fully guaranteed.

Specify them and look for the "Diamond" Trade-Mark before buying.

Let it be your guide to better Valve Service.

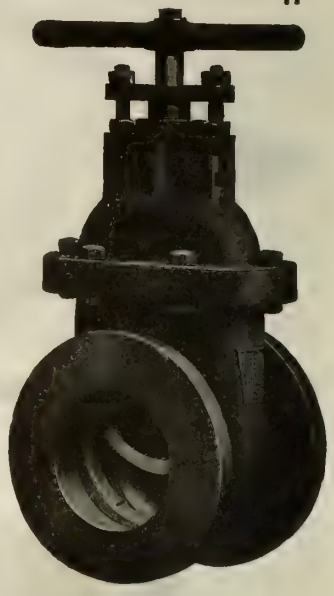
KERR
("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.



When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

Kerr Engine Co., Ltd., Valve Specialists **Walkerville, Ont.**

Homestead

Quarter Turn Valves close with a quarter-turn and remain tight without dripping or leaking. They're built to stand greater pressure than that for which they are recommended.

QUARTER TURN **Valves**

Up against the hardest proposition in your plant, Homestead Quarter Turn Valves will quickly earn their cost by eliminating leakages. No matter how severe the service, you need not worry; use Homestead Quarter Turn Valves for absolute safety. Use them wherever other valves fail.

Write to-day for a Homestead Valve.

Homestead Valve Mfg. Co.

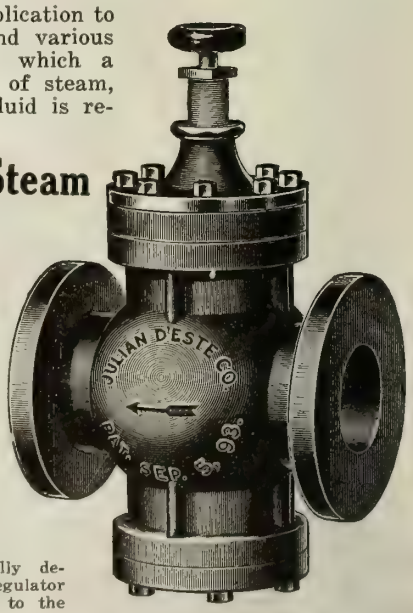
CURTIS Engineering Specialties

Universality!

For universal application to all the varied and various conditions under which a reduced pressure of steam, water or other fluid is required the

Improved Steam Pressure Regulator



has no equal.
It is compact and self-contained, without levers, weights or projections.
No glands or packing; no drip or leak of steam or water. Suitable for any boiler pressure; made entirely of metal: is a lock valve, very simple and sensitive.
Send for leaflet fully descriptive of this Regulator (contains price list) to the manufacturers.

MANUFACTURED BY THE

JULIAN D'ESTE COMPANY

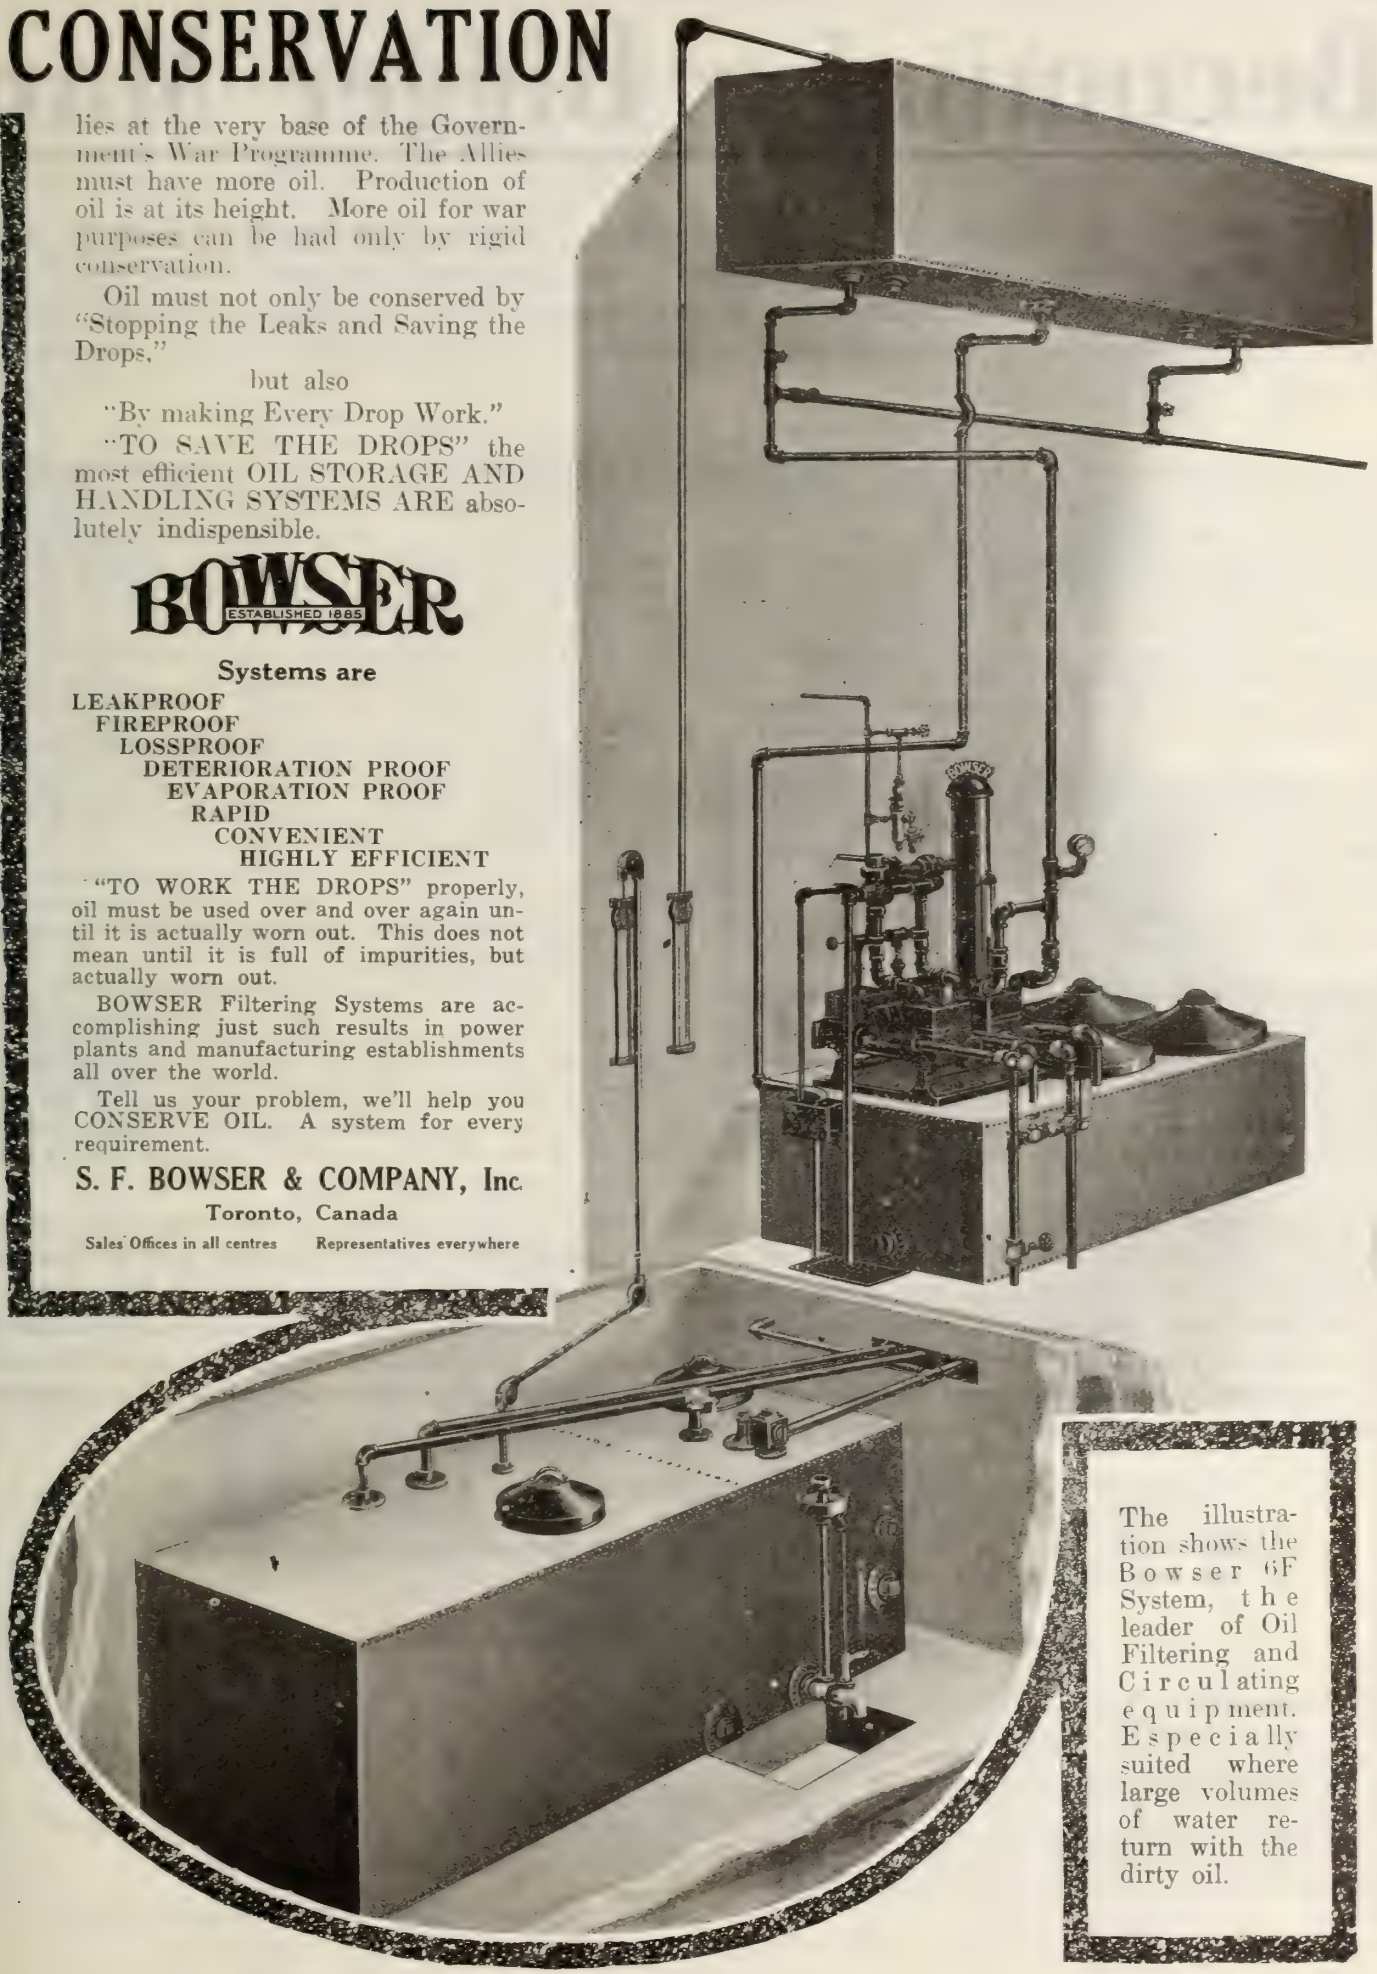
Toronto, Canada

Sales Offices in all centres Representatives everywhere



The illustration shows the Bowser 6F System, the leader of Oil Filtering and Circulating equipment. Especially suited where large volumes of water return with the dirty oil.

Becoming a Bigger Man

WHAT is the difference between some men you know and others known to you? Why are some men earning $3,000 a year and some $30,000? You can't put it down to heredity or better early opportunities, or even better education. What, then, is the explanation of the stagnation of some men and the elevation and progress of others?

We are reminded of a story. A railroad man, born in Canada, was revisiting his home town on the St. Lawrence River. He wandered up to a group of old-timers who sat in the sun basking in blissful idleness. "Charlie," said one of the old men, "they tell me you are getting $20,000 a year," "Something like that," said Charlie. "Well, all I've got to say, Charlie, is that you're not worth it."

A salary of $20,000 a year to these do-nothing men was incredible. Not one of the group had ever made as much as $2,000 a year, and each man in the company felt that he was a mighty good man.

Charlie had left the old home town when he was a lad. He had got into the mill of bigger things. He developed to be a good man, a better man, the best man for certain work. His specialized education, joined to his own energy and labor sent him up, up, up. To put it in another way: Charlie had always more to sell, and the world wanted his merchandise—brain, skill and ability. Having more to sell all the time, he got more pay all the time.

Charlie could have stayed in the old home town; could have stagnated like others; could have been content with common wages. In short, Charlie could have stayed with the common crowd at the foot of the ladder. But Charlie improved himself and pushed himself, and this type of man the Goddess of Fortune likes to take by the hand and lead onward and upward. Almost any man can climb higher if he really wants to try. None but himself will hold him back. As a matter of fact, the world applauds and helps those who try to climb the ladder that reaches towards the stars.

The bank manager in an obscure branch in a village can get out of that bank surely and swiftly, if he makes it clear to his superiors that he is ready for larger service and a larger sphere. The humble retailer can burst the walls of his small store, just as Timothy Eaton did, if he gets the right idea and follows it. It is not a matter of brain or education so much as of purpose joined to energy and labor. The salesman or manager or bookkeeper or secretary can lift himself to a higher plane of service and rewards if he prepares himself diligently for larger work and pay. The small manufacturer, the company director, the broker—all can become enlarged in the nature of their enterprise and in the amount of their income—by resolutely setting themselves about the task of growing to be bigger-minded men.

Specialized information is the great idea. This is what the world pays handsomely for. And to acquire specialized information is really a simple matter, calling for the purposeful and faithful use of time. This chiefly.

One does not have to stop his ordinary work, or go to a university, or to any school. One can acquire the specialized information in the margin of time which is his own—in the after-hours of business. Which means: If a man will read the right kind of books or publications, and make himself a serious student at home, in his hours—the evening hours or the early morning hours—he can climb to heights of position and pay that will dazzle the inert comrades of his youth or day's work.

IF business—BUSINESS—is your chosen field of work, we counsel you to read each week THE FINANCIAL POST. It will stimulate you mentally. It will challenge you to further studious effort. It will give you glimpses into the world of endeavor occupied by the captains of industry and finance. With the guidance of the POST, and with its wealth of specialized information, you, a purposeful man, aiming to go higher in life and pay, will find yourself becoming enlarged in knowledge and ambition, and will be acquiring the bases and facts of knowledge which become the rungs of the ladder you climb by.

It is the first step which costs. But this cost is trivial—a single dollar. We offer you the POST for four months for a dollar. Surely it is worth a dollar to discover how right we are in our argument. If yoou have the will to go higher in position and pay, sign the coupon below.

THE MACLEAN PUBLISHING COMPANY, LIMITED,
.—143-153 University Avenue, Toronto.

Send me THE FINANCIAL POST for four months for one dollar.

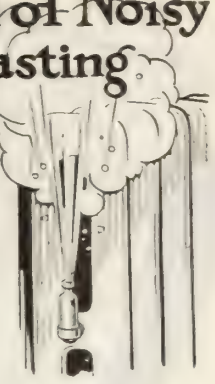
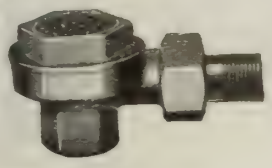
One Practical Way to Save Coal

Coal waste usually advertises itself; that is why we repeat our warning to watch your heating system. You cannot use your coal economically when the heat it makes is wasted by inefficient traps or air valves.

We are willing to spend our time and money to see whether your heating system is toeing the mark for efficiency. Are you willing?

Get Rid of Noisy Heat-Wasting Valves!





The Dunham Radiator Trap

Automatically removes the coal-wasting air and water from radiators; stops the pounding and hissing; quickly saves enough coal to pay for itself.

The DUNHAM HEATING SERVICE

The Dunham Radiator Trap is only one element in the Dunham Heating Service—a service that stops coal-waste from boiler to return pipe. We shall be glad to give you facts and figures on installations that are now making remarkable fuel-saving records.

Are you willing to hear the facts?

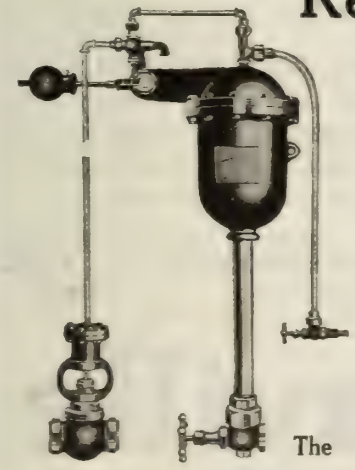
C. A. DUNHAM COMPANY, LTD., Toronto, Ontario

Branch Offices: Halifax, Montreal, Ottawa, Winnipeg, Vancouver, Calgary

Change-Over Work Our Specialty

VIGILANT

Automatic Feed Water Regulator



Regardless of load or firing, our latest Improved Vigilant feeds water to boilers automatically and keeps the level constantly within ¼ inch of middle gauge.

The Vigilant calls for no attention. It does its work automatically. With it installed you know there is no need for worry. You know there is nothing about it to get out of order.

And it's a fuel saver, too.

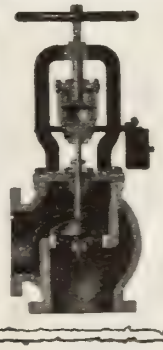
Ask for Catalog.

The Chaplin-Fulton Manufacturing Company

28 Penn Avenue - Pittsburgh, Pa.

DAVIS

Check Valves INSURE SAFETY



One of the Davis Steam Savers

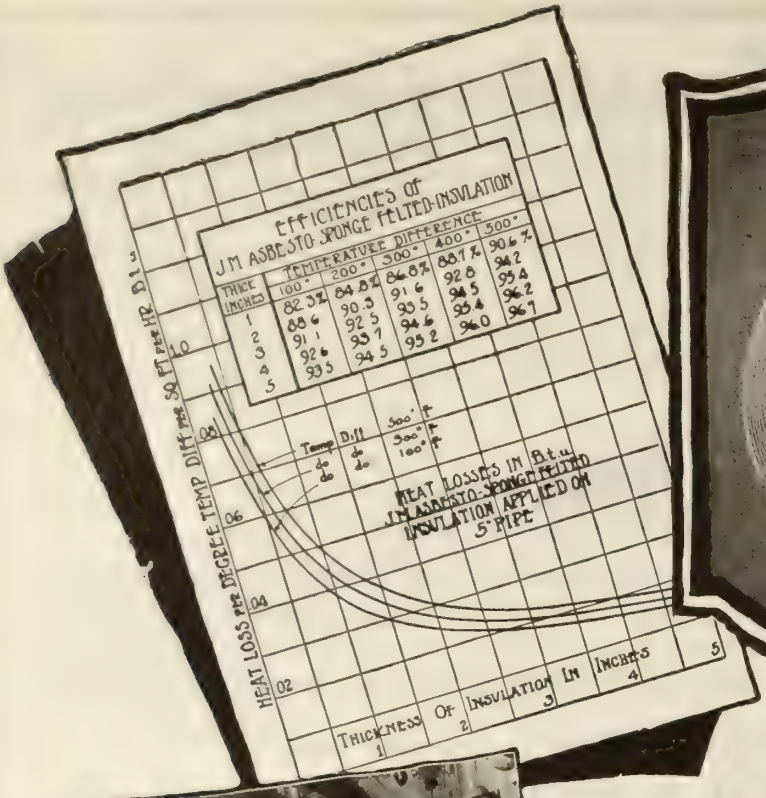
Let the Davis Stop and Check Valve insure safety in your plant by preventing boiler accidents. This valve automatically closes on a reverse flow of steam. An outside oil dash-pot, away from the effect of the steam, makes the action positive and absolutely reliable. The counter-weight lever is an indicator showing the valve action—can be tested by hand. It is as simple as a common stop valve, and requires no more attention.

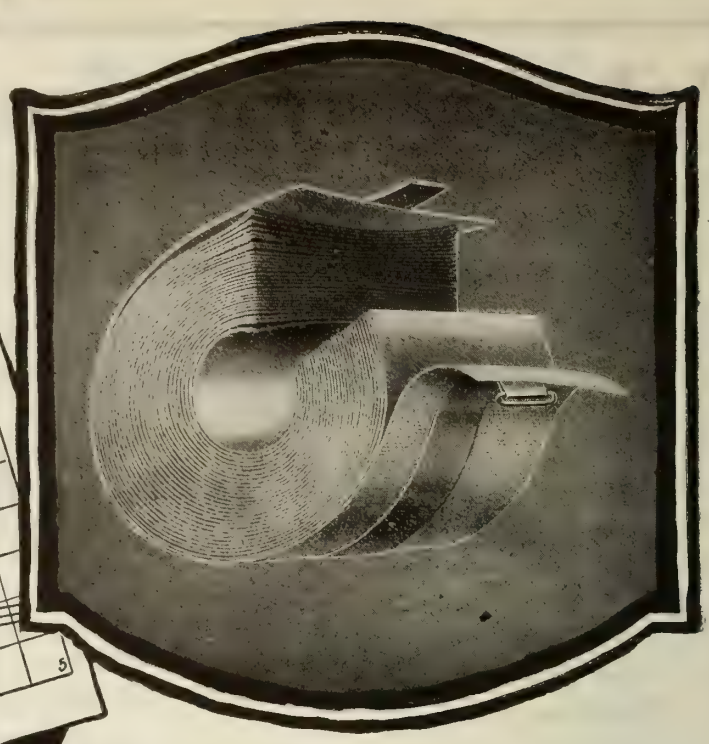
For your copy of the Davis valve booklet, just address the G. M. Davis Regulator Co., 434 Milwaukee Ave., Chicago. Branches in principal cities.

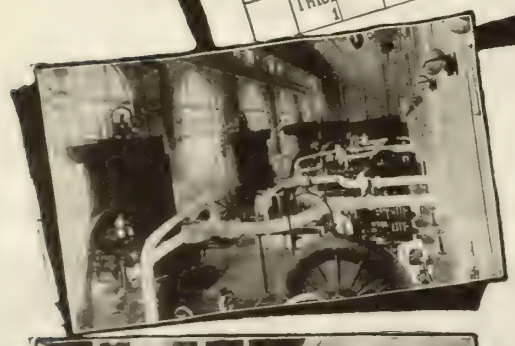
DAVIS VALVE SPECIALTIES

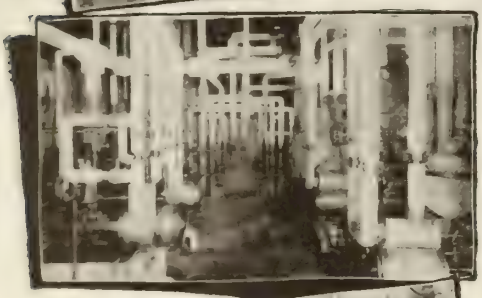
STEAM SAVERS SINCE 1875

If any advertisement interests you, tear it out now and place with letters to be answered.









90% Efficient
—and how you can know

YOU can't tell the efficiency of insulation by looking at it—or merely by price comparison. It must be a proven saver of heat. And nothing but laboratory and service tests will prove or forecast the saving. It is by data so obtained that the value of Johns-Manville Insulations are determined.

Johns-Manville engineers, with the service-proven efficiency records of each type before them, base their recommendations on a searching analysis of your service requirements.

They select from the several Johns-Manville Insulations that type that will most efficiently meet your requirements—not only on basis of heat saved but on basis of heat saved per dollar of expenditure. This is Johns-Manville Insulation Service.

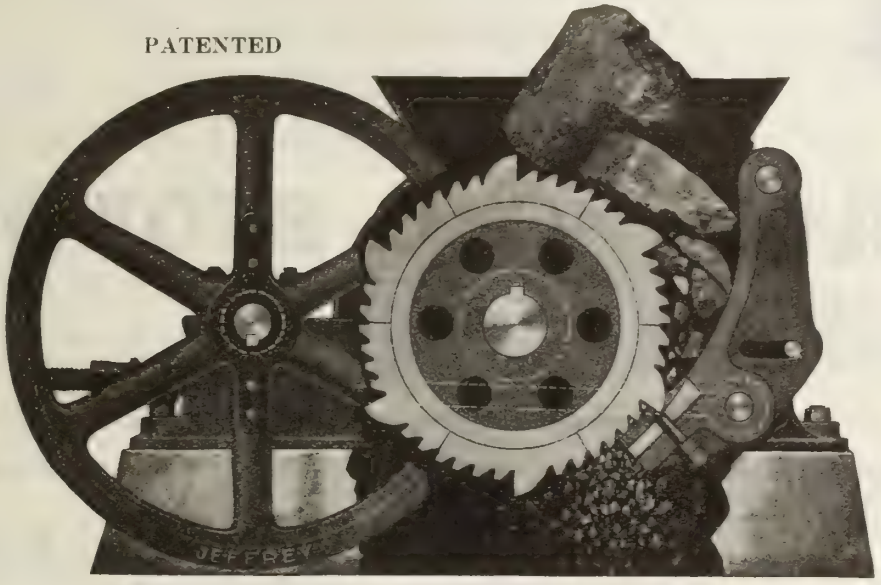
Where is Your Supply of Stoker Coal to Come From?

From all indications a repetition of last winter's coal shortage is inevitable. Manufacturers, power companies and railroads are storing coal in large quantities and the coal operator ships the sizes most easily loaded, that is, Run-of-Mine or Lump.



Make the Desired Sizes of Coal Yourself

By Using The

JEFFREY SINGLE ROLL COAL CRUSHER

In a single operation this machine reduces Run-of-Mine or Lump to the proper size for maximum heat efficiency in stokers.

Bulletin No. 141-4 gives complete information why the Jeffrey Crusher safeguards your coal supply and eliminates the worry of buying properly sized coal. Write for copy.

POTATO SCALE POWDER

A Simple, Inexpensive Means of Saving Fuel

Canada will face a serious fuel shortage next winter. Every pound of coal should be conserved—right now. A little POTATO SCALE POWDER in the feed water of your boilers each day will save many tons of coal for Canada in the course of a few months. POTATO SCALE POWDER removes old scale from the boilers and prevents any new scale formations, thus your boilers are able to do maximum duty with a minimum amount of fuel. No pitting, foaming or other troubles, due to impurities in feed water, where POTATO SCALE POWDER is used.

Made to suit feed water conditions and contains nothing that will cause the slightest injury to boiler metal or fittings.

Large power plants in Canada and United States are constant users of POTATO SCALE POWDER. Positively guaranteed. Try a barrel and watch the result.

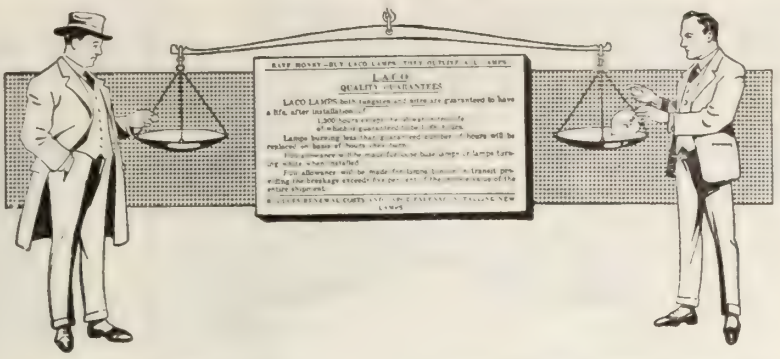
"Rock Bottom" Lamp Prices

The Value of a Lamp Depends upon Three Factors:—



INITIAL COST

One 40-watt LACO Tungsten costs 40c. One "ordinary" 40-watt Tungsten costs 38c.

LENGTH OF LIFE

But two 40-watt Laco Tungstens burn 3000 hours, while it takes at least three ordinary lamps to last as long.

CURRENT CONSUMED

And Laco Lamps have been proved to burn 25 to 50% less current, to effect the same light.

The savings on other styles and sizes of Laco Lamps are equally great.

Laco Lamps Are Guaranteed for 1500 Hours Useful Life
(excepting 60-Watt Nitro—guaranteed for 1000 hours life.)

No other Lamp is guaranteed for more than 1000 hours. Laco Lamps are also guaranteed to give the Candle-Power U. S. Standard Specifications provide.

Laco Lamp Prices Give the Purchaser Greatest Lamp Value

Let the Laco Engineers investigate your lighting problems and devise the correct installation to meet your needs.

If any advertisement interests you, tear it out now and place with letters to be answered.

In Canada's Biggest Industries

Where absolute certainty must be counted upon at all times, no chance can be taken with equipment.

In the big industries, especially, must every detail be efficient—the blow-off valve as well as the boilers, pumps and engines.

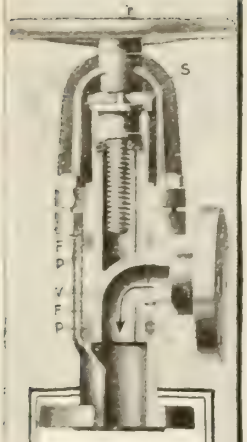
So, when the big Canadian corporations such as the following instal Yarway (formerly Simplex) "Seatless" Blow-Off Valves, their choice becomes an endorsement of the very highest character.

Canadian Explosives Co., Ltd., have 11.
Dominion Iron & Steel Co., Ltd., have 20.
Canadian Pacific Ry. Co. have 24.
Bathurst Lbr. Co. have 8.
Montreal L. H. & P. Co. have 24.
International Eng. Wks., Ltd., have 13.

and there are many others.

With the Yarway (formerly Simplex) "Seatless" Blow-Off Valve there can be no sudden opening and closing to injure tubes; the operation is simple, certain and safe; the valve does not leak; it requires but little attention as there are no weak places such as seats or discs to cut and scar; even the packing lasts for years. You can verify each of these claims by testing the Yarway on one of your boilers for 60 days. Return it if not satisfactory.

Write to-day, stating size of line, and whether screwed or flanged, angle or straight-way.



Operation: In closing valve shoulder "S" on plunger "V" engages the loose following gland "G" compressing packing "P" above and below the port, making an absolutely tight valve.

THE ANSWER IS NEVER!

How often should "John Crane" Soft Flexible Metallic Packing be renewed? Never. Six years ago an engineer started keeping tab on his fibre packing renewals. So far he has renewed it 18 times.

Six years ago a great many engineers installed "John Crane" Soft Flexible Metallic Packing for the first time, and they haven't renewed it yet. It still appears to be good for another six years and THEN SOME.

When you pack a plunger or rod with "John Crane," you don't pack it for months, but for YEARS. You don't take it out to renew it—just add another ring. There is no waste.

Simplicity, flexibility and ingenious mechanical construction of "John Crane" assure permanent freedom from expensive packing difficulties.

"John Crane" is made of sheet babbitt, wound evenly and spirally and lubricated between every sheet. Flexible and compressible as flax, yet better than flax in many ways.

No. 1 tells all. It also tells about our trial offer.

We cannot tell you all about "John Crane" here, but Bulletin

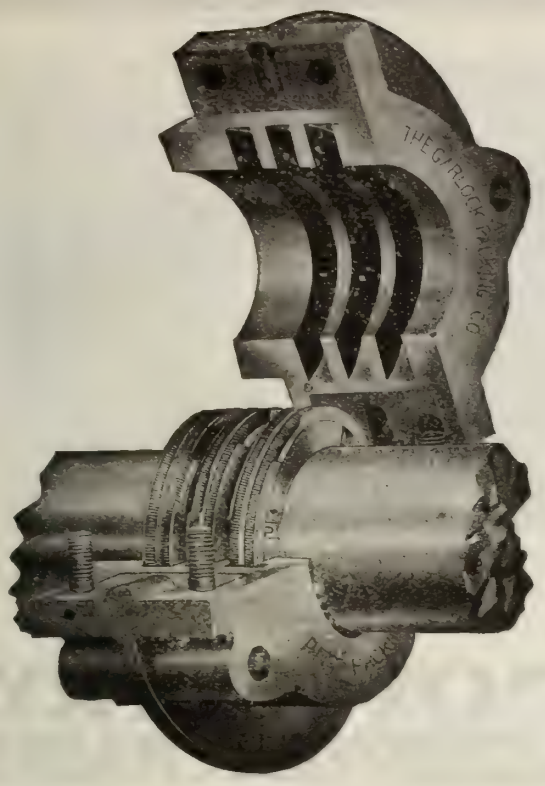
J-P J-P



GARLOCK Metal Packing

OUR position in the metal packing field is based on the principle that "No one style of metal packing can be made to meet all conditions." Working on this basis our experts study carefully the conditions surrounding each case, and with strict regard for mechanical principles, determine which type of packing is best suited to the conditions.

¶ The accompanying illustration shows our Flexible Packing, with split case, which is the most popular style and best all-round packing for stationary work, and when recommended by us to meet stated conditions, is guaranteed to give satisfactory service. This style is also made with solid or split-case to fit inside of stuffing-box, when packing space is sufficient to permit inside application of case and segments. All of our metal packings are so designed that the piston rod has absolute freedom of lateral movement without affecting the efficiency or increasing the friction of the packing.

¶ Next to correct mechanical design the most important feature of metal packing is the material used in the bearing rings. Our materials are made from formulas which long experience has shown to give the best results. A special grade of cast iron is generally used for bearing segments, in order to secure minimum wear and friction, but under unusual conditions, or when considerable condensation enters stuffing-box, bronze rings or segments of softer metal have to be used in the wearing parts.

¶ We can solve your metal packing problems, and we will give the usual Garlock guarantee of satisfactory service, if conditions are such as will admit of the successful use of any metal packing.

Write for catalog describing our many styles of metal and fibrous packing.

WHEN "Mike" spits on his hands he does a very natural thing. The tool is slipping because his hands are hard and slippery. Of course he could hold it tighter, but it's easier to soften up the skin. So "Mike" spits on his hands.

We looked at the belt problem this way more than twenty years ago. A leather belt and the palm of the hand are not so very different. Both are skin —one's thicker than the other, that's about all.

The leather is a growth of millions of separate fibres, and is porous. Unlike the hand, it has no life of itself—no natural oils to moisten it—but must be kept mellow and pliable.

A grease should be worked into the belt, where it can surround each fibre and lubricate it from its fellows. Thus they will "run in grease" and slide easily as the belt bends, instead of grating harshly together. The belt becomes pliable and mellow instead of dry and harsh. The surface of the belt will be clean, yielding, "velvety," yet not sticky, and will COHERE with the pulley faces.

Now, any grease so used has got to be a real preservative food, with no harmful acids, and should not oxidize, turn rancid, form sediment, or become stringy. Rosin and rosin oil is condemned by all belting authorities, and various vegetable and mineral oils, in their natural state, cause cracking or rotting within the belt and eventually destroy it.

Sticky belt dressings, while they stop the slipping for a time, are about as bad as glue upon the hands, and for the same reasons.

CLING-SURFACE is a **real preservative** treatment.

A CLING-SURFACE treated belt will run perfectly in all weathers, easy or slack under big overload, without slipping. It will not warp, tear at the laces, separate at the joints or gather static electricity. With CLING-SURFACE the life of the belt is prolonged, and its capacity for work greatly increased. It immediately becomes a cheerful, obedient worker, soon needing little or no attention, take-up or protection other than the occasional treatment with CLING-SURFACE, and always working easily, silently and efficiently.

CLING-SURFACE can be applied to **your** belts by any workman in a few hours. A treatment now means a definite step toward permanent freedom from all belt trouble, and money in your pocket, with practically no effort to put it there.

Our co-operation will assist you in this work. Let us send you a can for sixty days' trial.

Remember, use CLING-SURFACE and you won't need belt

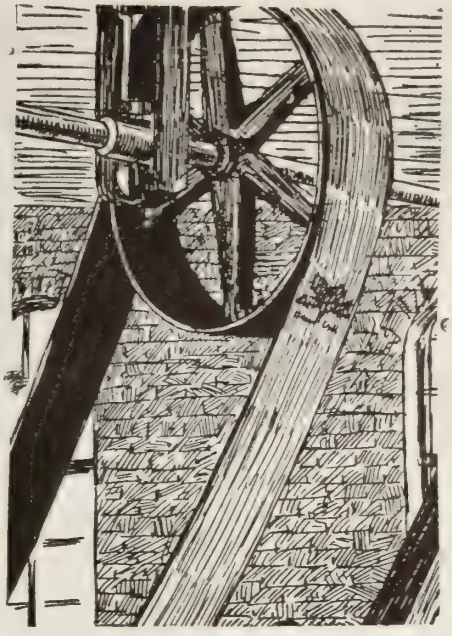
Mr. Chief Engineer—

Be able to say

"It's Working FINE"

when the Superintendent asks about the new belt you got your plant to buy.

Be sure to specify



D. K. McLAREN'S

Genuine British Oak-Tanned

LEATHER BELTING

when putting in your requisition for a new belt. And you'll ensure a long, trouble-free, efficient service.

Think what being able to say "It's working fine," will mean to you instead of having to report trouble every little while, as is the case in many places where precaution is not exercised in the purchase of belting.

D. K. McLaren's Leather Belting is made exclusively from close-trimmed butts of the finest selected hides, tanned by the old-fashioned but the proven most effective British Oak Tanning Process.

It doesn't require the attention and expense that is common where ordinary belting is used, because there is practically no slip, and it seldom requires tightening.

Many of the largest Canadian Plants are our steady customers. If you wish to ask them how they like this belting, we will be glad to send you their names and addresses.

GENUINE OAK

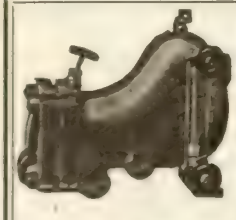
Why not Buy the Best, when in market for Packing?

HOLMES' Metallic Packing Is Guaranteed 3 Years

Lasts many times longer. 30 days' trial. Less oil. No cutting. Easily applied to any Steam Engine, Air Compressor or Gas Engine. Satisfaction or no pay. Write us.

HOLMES METALLIC PACKING CO., Wilkes-Barre, Pa.

Incorporated 1897



McDANIEL IMPROVED STEAM TRAP

FOR HIGH OR LOW PRESSURE.

Steam can't blow through. They have large discharge valves and cannot be flooded from sudden flushes of water.

MAY WE SEND ONE FOR TRIAL?

Reducing Valves, Pump Governors, Relief Valves, Exhaust Pipe Heads, Ejectors and Steam Separators.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID, Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D., Supt. Trades & Labour Branch

D. M. MEDCALF,
Chief Inspector of Steam Boilers.

ELECTRICAL SAFETY AND ECONOMY

ECONOMY
Renewable
FUSES

Cut Annual Fuse Maintenance Cost 80%

Economy "Drop Out" Renewal Links are responsible for this saving.

A "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.

A sustained arc is impossible.

It's the work of a moment for even a novice to replace the link and renew the fuse.

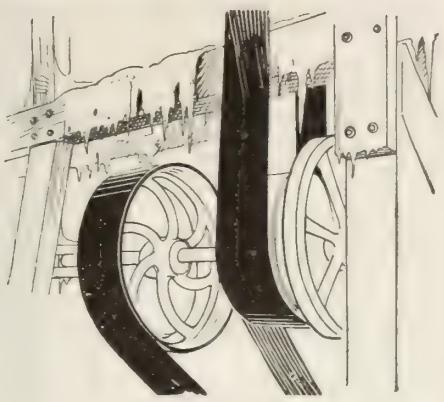
First in its field—first in efficiency.

Order from your dealer.

Write for Catalogue 24.

Economy Fuse & Mfg. Co.
of Canada, Ltd.
Unity Bldg. - Montreal

Manufacturers in Canada of S.& C.High Potential Fuses--to 150,000 volts.



Lanco Balata Belting
Works Well In Cold Places

This belt can in fact be used under any atmospheric conditions except those of heat.

This is a high-priced belt and you expect it to give long service. It does.

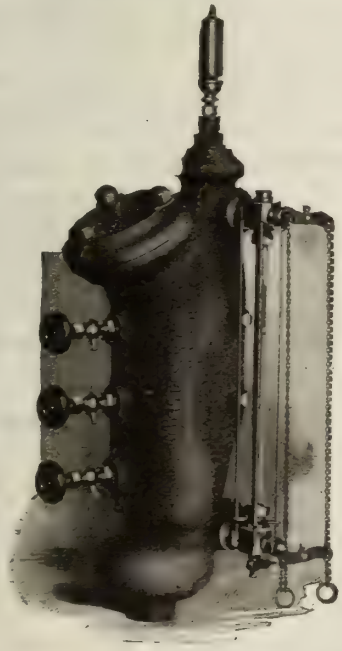
For work in wet or cold places you can buy cheaper belts that will do the work as well for a time, but would you not rather have a belt that would last longer even if you had to pay more for it?

Remember that changing belts is an expense and if you have to shut down your plant to make the change—and you sometimes do—the cost of the shut-down may be many times the cost of a Lanco Balata Belt.

We solicit the business of firms engaged in Mining, Stone Quarrying, etc.

Federal Engineering Co., Limited
172 John Street, Toronto

Water Must Be Kept At Its Proper Level—
Or Your Boiler Efficiency Drops



Exterior

When the water in your boilers rises above or falls below its proper level—it not only affects boiler efficiency, but **becomes dangerous**—you should know it instantly.

If you are depending upon a gauge glass you are taking risks. Rid yourself of all worry and care of boiler explosion in your steam plant by installing

THE ANDERSON
Safety Water Column

The "Anderson" sounds the high and low water alarm whistle plainly and unfailingly. With it you know whether the water is RIGHT or not.

The construction of the "Anderson" ensures you a big, reliable service. Nothing can go wrong.

The Anderson Safety Water Column is equally adapted for an old or new boiler—any make, size or description. Our illustrated catalog is worth sending for. Write now.

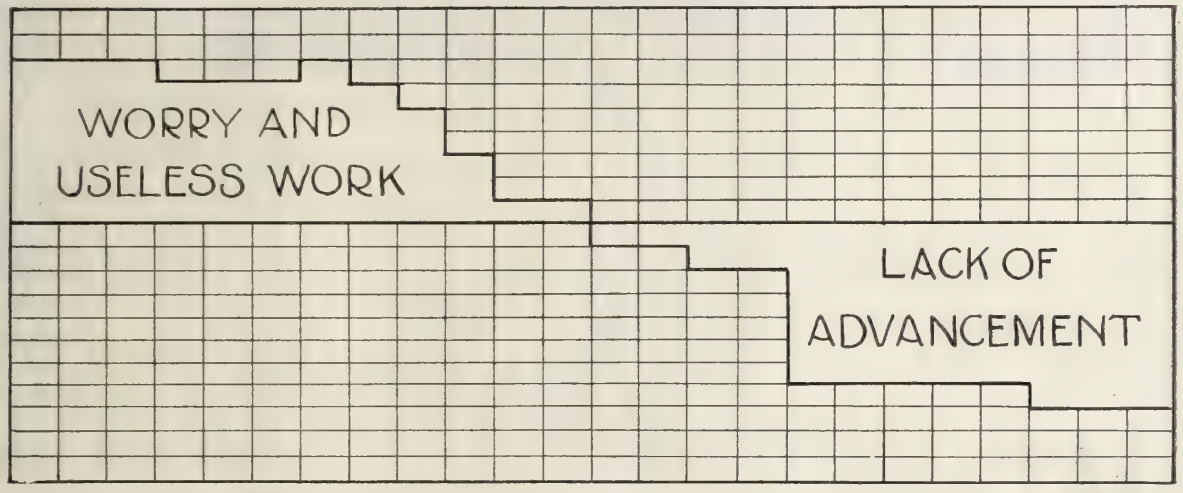
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

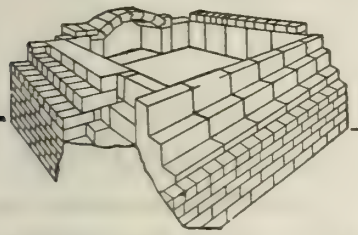
201 Royal Bank Building, Toronto, Ont.



Gates Boiler Furnace

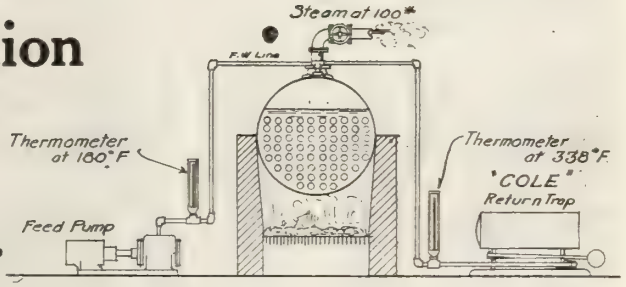
Patented 1916

Will last three times as long as ordinary good grade Fire Brick. These blocks are inter-locking, and made so that any handy man or fireman can renew them without disturbing any of the other brick work.

WRITE FOR PARTICULARS.

John W. Gates 2 St. James St., MONTREAL, QUE.

A Question for the Steam Engineer



Under these conditions—of alternative feed apparatus—how many lbs. of steam per lb. of coal would you expect?

GEO. W. COLE, Ltd. **2002 Dundas St. W.** **TORONTO**

ECONOMY!

In the Steam Plant

A remarkable number of dollars can be saved by having condensation returned to the boilers as pure **Hot** steam. This is what the "Morehead System" will do, automatically and completely—thus saving many dollars' worth of fuel in the course of a year.

The "Morehead System" does more. It effects economy in operation, gives freedom from all steam pump troubles, and maintains an equally-controlled uniform temperature throughout your plant.

The "Morehead System" offers you the simplest and most profitable way to handle steam condensation.

Requires practically no attention, needs no cylinder lubrication, will not race or run away, never sticks, takes little space, requires no foundation and will handle water of any temperature.

LET US SEND YOU SOME MORE FACTS ABOUT THE "MOREHEAD SYSTEM."

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CATALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.**

MACGOVERN & COMPANY, Inc.

The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH

Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.

Nut with Nut-Guards

INGLIS BOILERS

Inglis quality has not been attained in a day or a month or a year or two. It represents the fruit of over half a century in meeting the requirements of boiler users.

Inglis boilers are Canadian standard in materials, workmanship and efficiency. They ensure a lifetime service with a minimum of repairs.

We build boilers of all kinds for any service. We are also sole Canadian manufacturers of the Erie City Water Tube Boilers. Absolute satisfaction guaranteed.

Write us for prices and specifications.

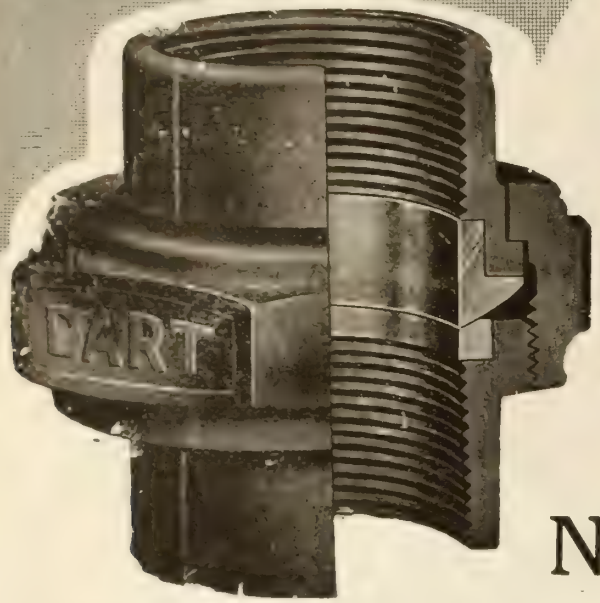
"DART" UNIONS

No Deterioration Here



That Joint Will NEVER Loosen Up

THE DART UNION IS THE KEY TO A PERMANENTLY TIGHT JOINT.

A leaky pipe connection is a thing of the past wherever it is used.

Dart Union Pipe Couplings stay tight because of the Bronze to Bronze face and seat which cannot rust or corrode, and the extra heavy iron parts which will stand unusual strains without any signs of stretching or pulling apart.

DART UNIONS SAVE TIME IN MAKING CONNECTIONS. The Ball-shaped Joint enables you to connect pipes quickly and without bother whether they are in or out of alignment.

NO UPKEEP COST. NO REPLACEMENT COST. NO LOSS FROM LEAKS.

DART TRADE MARK

ORDER FROM YOUR JOBBER and be sure this trade mark is on the kind you get—it's your guarantee.

A Barrel of Boico Saves Tons of Coal

BOICO is the One Sure and Safe Cleanser of Boilers

Quickly Removes and Positively Prevents Any Further Formation of Scale in Any Boiler

Think of the price you are paying for coal now! Every ton wasted runs into a lot of money. BOICO will save you this wasted expense by ridding your boilers of the cause of this waste—boiler scale. BOICO cleans the boilers thoroughly of the worst scale formation. While it's saving fuel it saves oil and packing, too.

Contains nothing that will prove injurious to the boilers or their accessories. Never causes priming or foaming.

When you use BOICO you get the results you are after. You should at least test it.

WRITE FOR FREE TRIAL.

Anti-Clinker Shell Bar Grates

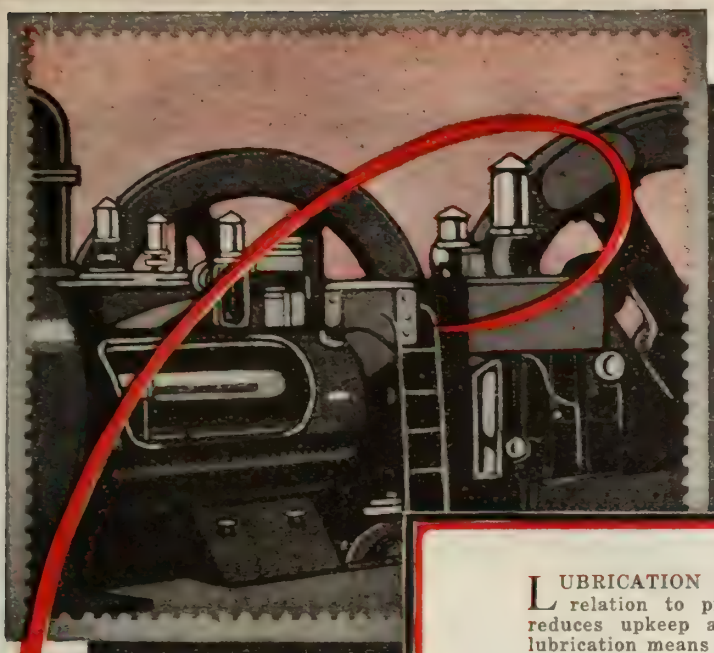
Give You More Heat With Less Coal

The scientific draft principle of Anti-Clinker Shell Bar Grates give as much as 25 per cent. more heat to fuel gases. There's no waste. There's no clinker formations, warping or twisting and the grates are easily cleaned. When you adopt Anti-Clinker Shell Bar Grates you save time, fuel, labor and money.

Copper Asbestos Boiler Gaskets

Made of copper, with pure asbestos cord-filled corrugations. They stop leaks in pipe lines; never blow out and never stick. Try them.

Shell-Bar } Boico Supply, Limited
376 Dufferin St., Toronto, Canada



A DIRECT CONNECTION

LUBRICATION always has a direct and important relation to production costs. Proper lubrication reduces upkeep as well as operation costs. Proper lubrication means a greater output, less repair bills and more years of service from power plants and other machinery.

Correct lubrication requires not only high quality lubricants but *carefully selected lubricants.* To properly lubricate your plant you must use the right lubricant for each specific purpose. Do not let poor lubricants or improper lubrication destroy expensive machines before their time. Imperial lubricants are always cheaper in the long run. There is indeed a direct connection between lubrication and your cost account book.

Our Lubrication Engineers will gladly advise you on anything relating to lubrication. Write us at 56 Church St., Toronto. All enquiries will receive prompt attention.

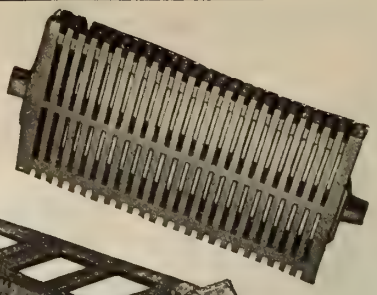
Cyclone Grates



are your best insurance against fuel waste. Their 60% Air Space and 90% Underdraught prevent the formation of clinkers. Their new jarring, shaking movement sifts the ashes through—but not one lump of good coal. You can use economically the highest grade hard coal, the lowest grade soft coal, even screenings, with these Cyclone Shaking and Dumping Grates. And if you want proof, just ask us for the names of users.

30-DAY Free Trial Offer

This offer fully protects you. We make it because we are confident you will be well pleased with our Cyclone Grates once you have given them a trial.
Ask for particulars to-day.

The Kaiser Wasted His Power—and Went Down to *DEFEAT*

Allied pressure together with friction between militarism and the people finally ended in speedy collapse of autocracy.

Reduce the Friction in Your Machinery *it Eats Power*

Make sure that friction is greatly reduced in your plant by using

Hoyt Babbitt Metals

and you save power which in turn saves fuel.

Hoyt Metals are giving super-service all over the world. Would our annual sales total over $5,000,000 if Frost King and other Hoyt Babbitts were not far and away superior.

Try Frost King—our general purpose Babbitt. We've put 40 years' Babbitt-making experience into compounding it.

Try Nickel Genuine—is as perfect as an alloy can be made for use in gas and gasoline engines, all classes of marine engines and automobile engines.

Frost King and our specific purpose Babbitts are described in the Hoyt Catalog. Also how these super-service Babbitts will lighten the Babbitt expense in your plant is told. Write for copy.

THE OLD FASHIONED WAY

--he's a good fireman; he gets up steam all right--BUT--

the cost of firing is at least 15% more than it needs to be

What is wanted here is a modern stocking equipment—the

JONES UNDERFEED STOKER

The "Jones" equipment automatically maintains a uniform steam pressure; it responds instantly to load fluctuations and will make 85 tons of coal go as far as 100 tons would go with the man with shovel.

No Losses Through Grates—
There are None

Simplicity is another of its cardinal virtues. No parts move in contact with fire. Works with very little attention and **saves labor.** Does away with a lot of fire worry. **Burns less coal and cheaper coal.** You get a steady steam pressure, regardless of load.

WOULD YOU LIKE TO GET IN TOUCH WITH SOME USERS OF THIS STOKER? WRITE US.

Jones Underfeed Stoker Co.
Limited

THE JONES MODERN WAY

Babbitt
—Adjustable—
SPROCKET RIM
with chain guide

Simplifies piping arrangements, reduces danger and expense, makes overhead or out-of-the-way valves easy to operate from long distance.

The "Babbitt" can be quickly attached, five minutes and a wrench will do the job. To operate—simply pull a chain —that's all.

Every valve should have a Babbitt. It's the **only** safe way to open or close a valve.

When Buying Thermometers

There's Just Three Things to Remember—

First, you must have accuracy and sensitiveness—

Second, durability is absolutely essential—

Third, the thermometer must be suitably constructed for the intended application.

Accuracy, sensitiveness and durability are absolutely guaranteed in

"Crescent" Thermometers

And with nearly seventy years of experience to our credit, we are qualified to properly interpret your needs.

Our Catalog P.H. 200 illustrates and describes "Crescent" Thermometers for every application. Also test thermometers, glass thermometers, etc.

TURBO BLOWERS

Burn Cheapest Coal Mined

and increases steaming capacity to 50 to 100% of Normal Rating of Boilers without doing slightest injury to Boilers

Coal is the biggest expense of your power plant. With **Coppus Turbo Blowers** you make steam with the cheapest kind of coal—with fuel that even looks like black dirt—and at the same time increases your boiler capacity 50 to 100 per cent. In a nutshell here is what **Coppus Turbo Blowers** mean—a saving in:

—losses from incomplete combustion;
—losses from choked grates and frequent attempts at cleaning;
—losses from extra work and worry in the vain attempt to properly work fires with only one element of combustion—coal—under control.

Further, **Coppus Turbo Blowers** give, by their instantly adjusted control of draft, a
—quick pick-up power on peak loads;
—sustained over-power for loads beyond the ordinary capacity of the plant;
—and the money-saving, capacity to burn anything in the form of coal with which the power plant man may have to contend in these days of great fuel scarcity.

You should investigate Coppus Turbo Blowers without delay. Ask for catalog and further information.

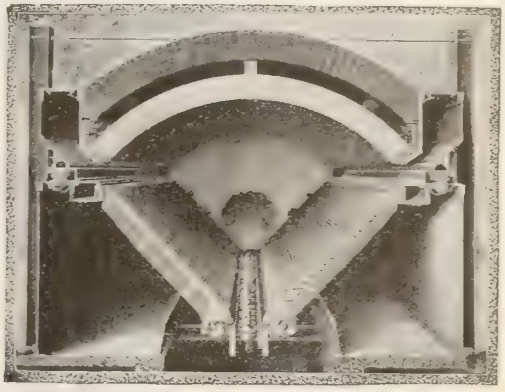
MURPHY AUTOMATIC FURNACES



The Webster Vacuum System of Heating

can be likened unto the Matterhorn. It has an individuality all its own. From its pinnacle of fame it commands everything in sight.

The Webster System cannot be anything but a good system because of its simplicity and excellence of operation.

It is a **Vacuum System,** which means, crudely, that steam leaving the boiler is sucked through the radiation, no matter where placed, and made to perform its functions to the last ounce.

But the real beauty of the thing is this: Your heating, or a large part of it, can be taken care of by the use of **Exhaust Steam from your Boiler. Think of it,** steam that you would otherwise waste can be developed into heating units by the use of the **Webster Vacuum System of Heating.**

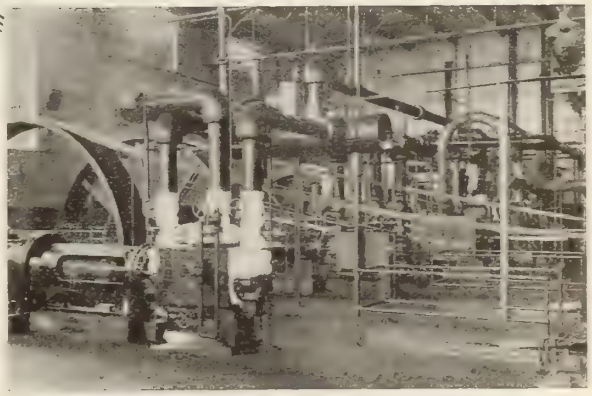
"The Best We Ever Had"

That's a pretty strong statement, but it indicates in no uncertain way just what the Harris Abattoir Co., West Toronto, Ont., think of Nonpareil Cork Covering. On June 7, 1918, Mr. H. D. Tefft, Superintendent, wrote:

"Referring to the Nonpareil Cork Covering you applied on the brine and ammonia lines throughout our plant. You will remember that this cork covering was put on about a year and a half ago, and we are pleased to say it has given the best satisfaction of any refrigerating pipe insulation we ever had."



Nonpareil Cork Covering on ammonia lines in the plant of the Harris Abattoir Co., Ltd., West Toronto, Ont.

Mr. Tefft is in a position to make comparisons, too, because the Nonpareil Cork **replaced** fibrous coverings that did not prove satisfactory.

There are good reasons why Nonpareil Cork Covering stands up under hard service. It is made solely of pure cork, which is cellular, not fibrous, in structure. Hence it does not suck in moisture by capillary attraction. If properly applied and given a reasonable amount of attention, Nonpareil Cork will save in ordinary cases enough refrigeration to pay for its cost in twelve months and will keep on saving refrigeration for years after that.

AN ESSENTIAL

Is Mechanical Refrigeration essential in my Business? You may have asked yourself this question many times. Or if you are at present the owner of a Refrigerating Plant you have doubtless struggled with the problem of improvements and additions. These are natural questions and should not be passed over lightly.

A function of the York Organization is to help you over the top in matters of this kind, with information—data—advice. If a prospective customer is well and truly advised and acts accordingly, he is sure to install a plant that will be a credit to the Industry, and even though we do not make the sale, we benefit indirectly.

Information from our Engineering Department, data from our Sales Engineers, and even advice from a Financial viewpoint, we are prepared to offer you as a part of the York Selling Plan, without cost or obligation on your part. Others have taken advantage of this offer to their lasting benefit. We do not believe you can afford to pass it by.

Think it over and write us if you are interested.

These refining grinders reduce ordinary ground pulp to an even finer texture for the better grades of wood pulp paper.

Making One Belt Do the Work of Three

IN a big Ontario paper mill this refining grinder drive had been a glutton for belts.

Ten months from 8-ply belts was considered exceptional service.

The superintendent was finally induced to try Goodyear "Extra Power." We prescribed 7-ply to replace the former 8-ply belt, giving a lower initial cost.

Now, after two and a half years, the superintendent writes of continuous, twenty-four hour a day service for all that time.

Just three times the service previously known. Less than one-third the cost.

Further saving — "Extra Power" gave *continuous* service. Only *one* stop to apply *one* belt in two and a half years.

This problem of belting costs is too vital to be decided off-hand. Belt life and belt performance must be balanced against belt price.

Thousands of executives who buy belts on facts, who keep belt costs, are turning to "Extra Power." It is the dominant factor in the belt field to-day.

It will be worth *your* while to talk with a man trained in belt problems by Goodyear. It places you under no obligation. Just 'phone, wire, or write any branch.

POWER HOUSE

Engineer's Life Not Always a Bed of Roses

The First Instalment of This Article Appeared in the August Issue—The Present Article Deals With the Reconstruction of the Plant and the Present Layout

By S. BALMFIRTH

THE original plan of doing the work was to use a locomotive type boiler, or boilers, set them up on skids, and run temporary mains to the existing steam lines. This plan, unfortunately, was considered impracticable, first on account of the heavy load on the bunker roof, which forms the yard, and secondly on account of it being almost impossible to erect a temporary stack high enough to carry the smoke from the hospital windows.

So the writer was in the unhappy position of the contractor, after the church vestry had decided:

First—To build a new church.

Second—To use the material from the old church to build the new one.

Third. — To use whilst the new one the old church was being built.

Prior to the beginning of this alteration the writer had had the pump-room wall removed below the engine room floor and the wall above carried on steel beams and columns. Whilst this cooled off the pump room, it heated the boiler room, so a large air shaft was put in over the pipe, tunnel and carried out above the power house roof. This carried away quite a lot of heat and improved the conditions somewhat. Removing the wall also gave more room, which was sadly needed, and especially so when the first boiler was removed.

PRESENT BOILER ROOM FROM FIRING FLOOR LEVEL

Work was begun the last week in June, 1916. The first thing to be done was to get more room to work in. Accordingly the old heating main, consisting of 16 in. by 14 in. pipe and fittings, was torn out. This heating main was shown in the old plans.

The building contractor had begun work on the excavation for the new fire room. The plans shown were adhered to fairly closely, about the only change being that the steam main was made into a ring main.

Small temporary lines were run to take care of the high pressure services so as to allow of the old valves and other fittings being used again, and also to give room for the men to work in handling the boilers. These alterations had to be done at night or on Sundays so as to interfere as little as possible with the routine of the hospital.

To take the place of a 6 in. live steam main for laundry, pasteurizing department, cooking, and sterilizing services, two 2 in. lines were run, and in the winter of 1916 the whole of the hospital service, lighting and heating included, was handled on the 4 in. auxiliary main.

By this time there was considerably more head room in front of the boilers, the floor of the boiler room had been cut up and the new foundation for the single boiler built, and the firemen were walking around the boiler room and pumps on planks.

There was considerable seepage into the new fire room, which was five feet below the level of the old one, so it was found necessary to keep one pump continually pumping out the excavation into the sewer, which was about fifteen feet above.

The east wall had been removed below grade line, and the portion above grade carried on steel beams and columns. This had been done in the usual manner by needling the wall, carrying one end of the needles on the boiler wall and the other end on heavy timbers. The removal of this east wall had also taken in with it the tunnel connecting the boiler room and coal bunker. The removal of this wall disclosed the fact that the breeching had no end wall but was built up to the building wall. It was not discovered until the reduced draft and consequent lowering steam pressure turned out the whole engine room crew to find the cause. So the bricklayers had to hurry and build a dry wall in the end of the flue and plaster it over, after which there was no more trouble from that source.

This made it necessary to devise some means of getting coal to the boilers, so 2 in. by 4 in. scantling was lag-screwed to the wall of the building above ground

level, and brackets of 2 in. by 4 in. scantling built on to the scantling. A trough of 2 in. by 10 in. plank was laid on the brackets, and the bottom of it covered with 16-gauge iron. A single chain carrying 2 x 9 flights dragging along the bottom of the trough was driven by a ¾ h.p. motor that happened to be around the job. The flights discharged the coal into a sheet iron concrete chute which the contractor obligingly loaned. It was necessary to use two countershafts to get the reduction of speed. The rig was rough and ready, the motor and countershaft were perched on a platform fastened to the side of the building in the same manner as the trough. The writer never heard of a flight conveyor being a new thing, but judging by the adverse prophecies of the contractor and others, it must have been so in the locality. Anyway, in spite of the calamity howlers it delivered the coal where it was wanted, the trolley beam and bucket having been left in front of the boilers.

Once in a while some fireman would let the bucket run off the end of the beam and down into the hole by way of breaking the monotony, but on the whole there were very few accidents, less even than might be anticipated in a job of this description.

One of the first shut-downs, which were almost invariably made at night, was to cut out the Cochrane heater preparatory to moving the same. It must be remembered that this heater was permanently connected to the exhaust main in such a manner as to form part of it, so before it could be moved the exhaust main had to be blanked off.

By breaking the exhaust pipe of the 25 kw. set, and running a temporary exhaust pipe out through the office window, lights were kept on the building.

Unfortunately, whilst there was quite a let the bucket run off the end of the the plant there was not a muffler or exhaust head, so the exhaust was open and unconfined, and made its presence felt. The engine runs at 600 r.p.m. and was carrying 50 per cent. overload, and at night the noise could be heard quite distinctly. Some of the neighbors objected quite strenuously, but then one cannot please everybody.

So the steam connections to the heater were broken and the two ends of the exhaust pipe blanked.

If the plans of the old lay-out are referred to it will be seen that the outboard exhaust runs along the east side of the boiler room. In the new lay-out the exhaust pipe runs along the west side of the room. Really, the old 9-inch low-pressure heating main to the main building forms part of the exhaust line, so one of the next steps was to connect the exhaust line to the 9 in. low-pressure line.

The weather was getting cool, so live steam was used to heat the buildings whilst the exhaust line was open.

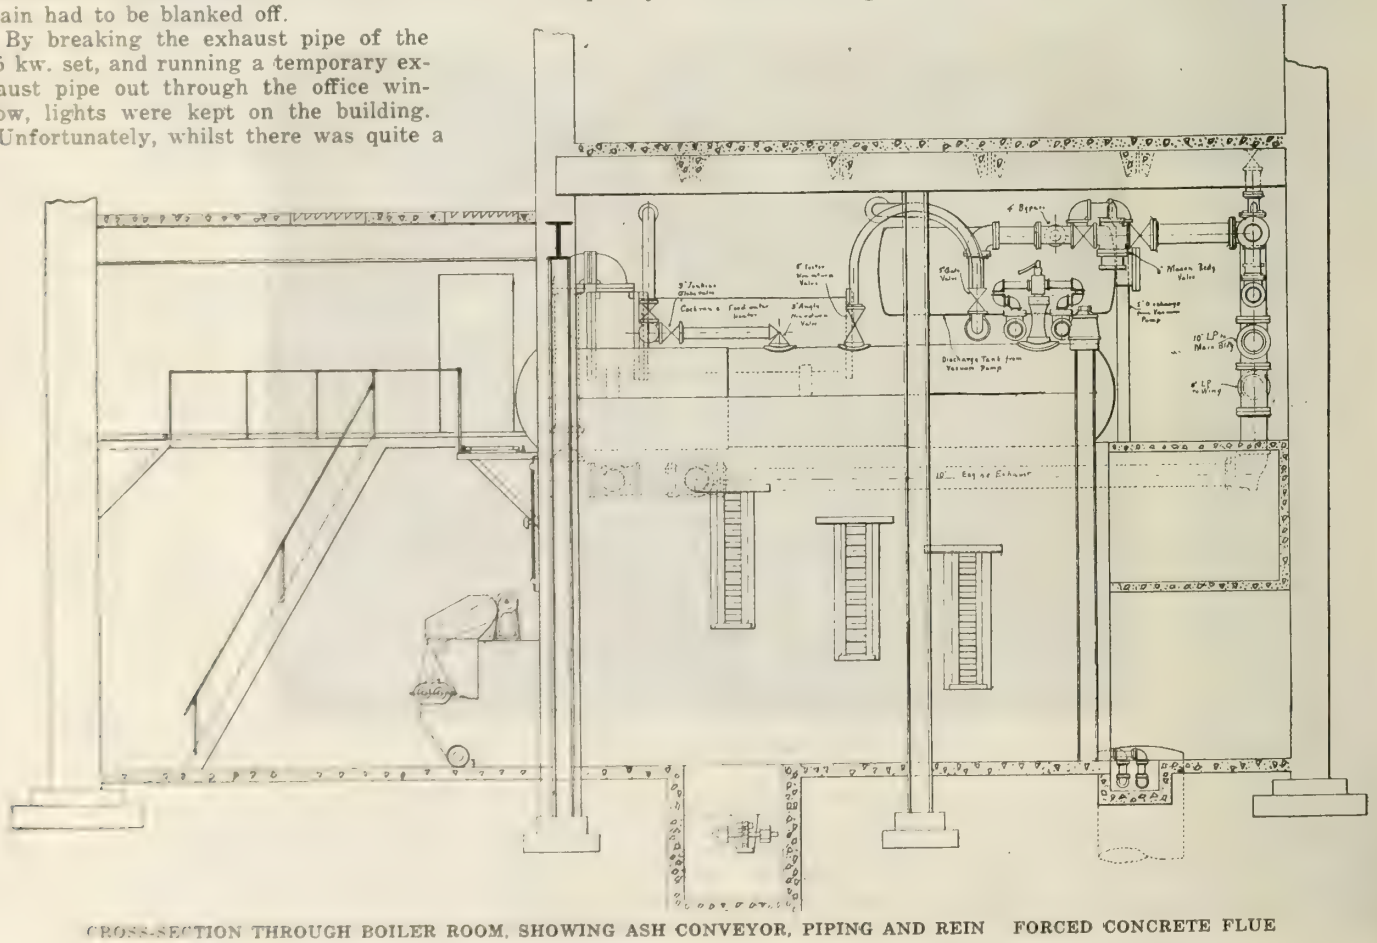
The same small set was run for lights, and the exhaust main pulled out where it entered the pump room, and by having the new pipe joined together as far as possible in the daytime, it was possible to get the connections made in one night. Outlets were left off for the exhaust from the pump and also for the Cochrane heater and the west wing and domestic hot water generators. In connection with this low-pressure main, the oil extractor comes before the heater, not after it.

The temporary steam lines being in place, No. 3 boiler was dismantled. In order to cut this boiler out it was necessary to close down the whole plant for a short time, because, as shown in the first portion of this article, there was only one valve on each boiler, and even had there been more it would not have helped in this case as the main had to be cut, so accordingly the auxiliary was shut off and the boiler No. 2 shut down, and the main header flanked at the 10 in. tee. This also cut off the 8 in. engine main, so that the auxiliary became the only main.

When it came to removing the 5 in. gooseneck band from the top of the boilers this was found to be impossible as there was not sufficient room to get it down (as a matter of fact these pipes were installed first, originally, and the floor above them laid in afterwards) so the pipes had to be sawn in two; 5 in. extra heavy steel, 2 ft. 9 in. headroom, temperature 150° in the shade—some job.

The stoker on this boiler was dismantled and taken outdoors and the brickwork pulled down and the rubbish cleared away ready for moving round. It had been the original intention to move the whole boiler intact without cutting, but tackle heavy enough could not be obtained and the room available was insufficient even if tackle could have been found.

The front and back nipples and circulating tubes were burned off and the nests of tubes lowered to the ground. These had to be carried forward and their whole length turned and laid on the new foundation. However, as there was

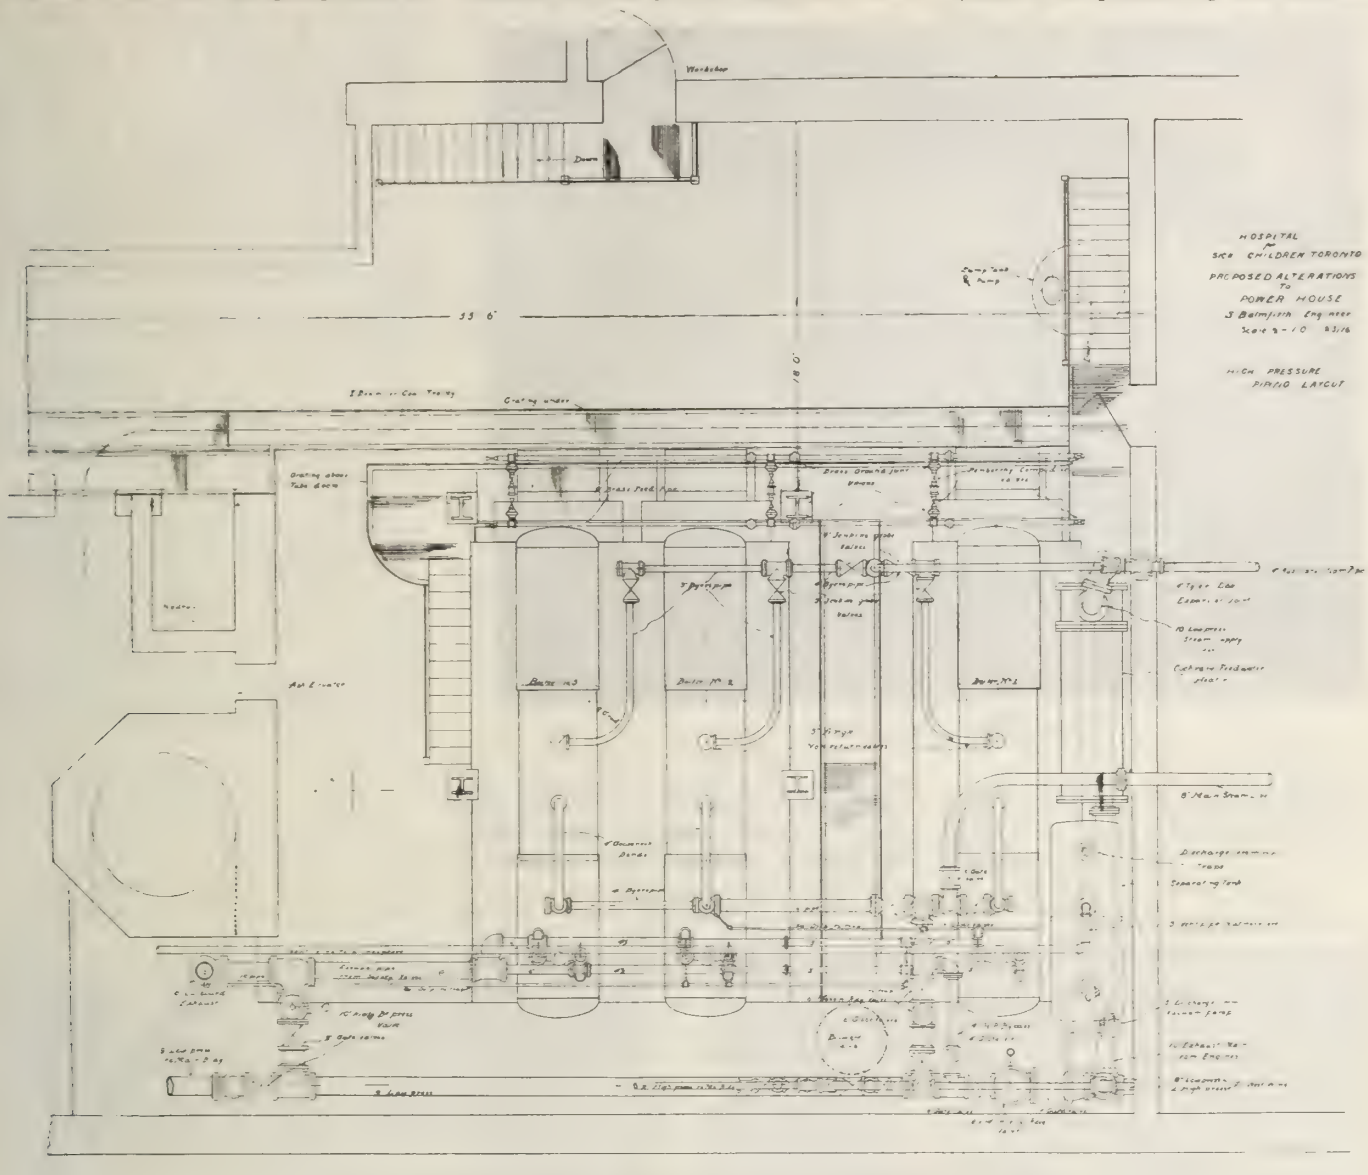


CROSS-SECTION THROUGH BOILER ROOM, SHOWING ASH CONVEYOR, PIPING AND REIN FORCED CONCRETE FLUE

only about fifteen feet of room in front of the boilers, and tubes about nineteen feet long over all, it was necessary to carry them right into the pump room in order to get sufficient room to swing them.

This being done, attention was paid to the steam drum. However, since the separating tank and feed water heater were to be above the boilers in the new layout, these were hoisted up to the ceiling and left hung on straps attached to the I beams.

Everything being clear, the moving gang started on the boiler drum. If there was not sufficient room for the tubes, there was even less for the drum, which was 24 feet long and 4 ft. diameter. The back end was lowered to the floor and front end left in the air, the only way in which it was possible to get it turned round on account of the lack of space, so it was held at an angle of about 45°, the front close up to the ceiling and the back dragging on the ground. There was still considerable piping close to the ceiling, and with the tank and heater in position there was not much more than two or three inches clearance past the stoker of boiler No. 2. When the boiler was about halfway round, the contractor quit the job, or rather his men did—just walked off the job at noon and never came back again—so there was nothing else left to do but to tackle the job ourselves. Accordingly, the day after Christmas day we started in. There were about five men on the job, two men on the boiler drum hauling on the tackle, one man at the back end with a crow bar easing it along, another steadying the drum, and the writer directly underneath the drum. Everything was going nicely, the back end of the boiler was being coaxed around into position, and had possibly ten feet more to go, when without an instant's warning there was a crack and a crash, and the drum was down amongst the crowd. It was the first time in his experience that the writer worked under a swinging load, and it is most likely to be the last. It came very near being the last, anyway. However, he moved very swiftly and stayed not on the order of his going, although that would not have done much good had not the drum fallen on the hopper of the stoker, which threw it over on to the new low-pressure main and against the engine room wall. The material damage was a broken stoker frame (which was patched up and the stoker kept running for another six weeks), flange on 10 in. low-pressure main and 4 in. L on pump suction line broken.



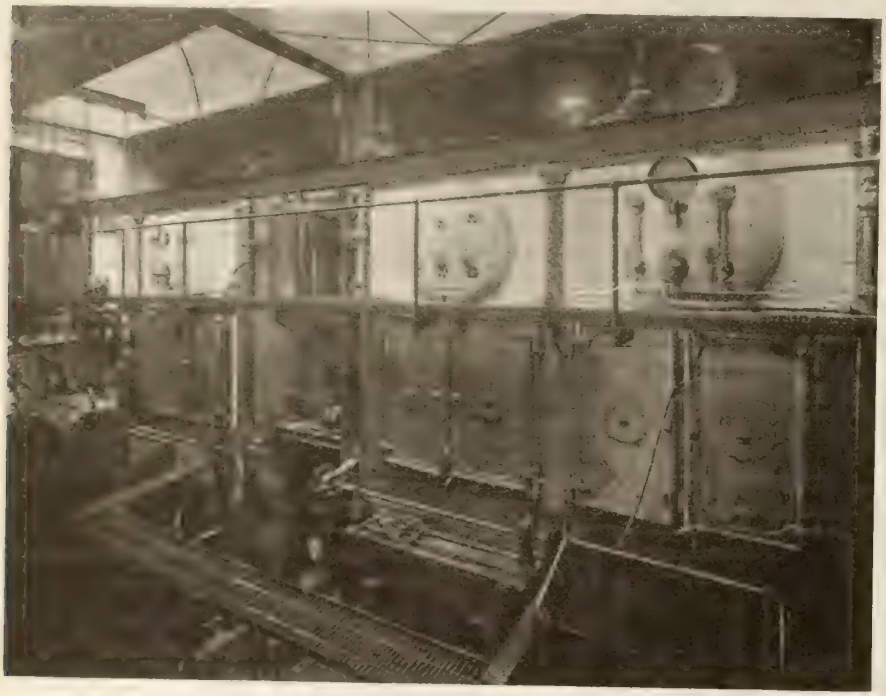
PLAN OF NEW BOILER ROOM, HOSPITAL FOR SICK CHILDREN, TORONTO

Amongst the men, the damage amounted to various bruises and abrasions, and the writer got a very hot shower bath as he passed under the same suction pipe. Moral: Put not your trust in another man's tackle.

However, as none of the men had lost his nerve the drum was picked off the steam main, the stoker got running, and the suction pipe repaired. Next morning the job was done. The back circulation tubes of the boilers were cut up and annealed and used for nipples.

Now began the hard times around the plant. As already mentioned, the floor was up and the firemen were walking around on scaffold planks. No. 2 boiler was stoker fired, but the No. 1 stoker on No. 1 had been removed and the front wall bricked up. The east side wall had been opened and two doorways built in and a lower half front braced up to the

side wall. Herring-bone grates were fitted and the boiler put in service. Since the floor on the east side was five feet lower than the floor at the front, a wooden platform was built the whole length of the boiler and about 9 feet wide, narrow enough, surely, for a firing floor, but as wide as was permissible.



BOILER ROOM FROM GALLERY LEVEL

It was not long before it was seen that No. 2 stoker was badly damaged from its collision with No. 3 drum; to relieve it as much as possible, No. 1 was put on forced draft.

The writer picked up a 40 in. fan and 5 h.p. motor. The motor was half buried with coal all the time, but we managed to get steam enough, which was the main consideration just at that time. Also we were able to burn anything that was black, which was another great help that winter, as soft slack was at a premium. That plant was certainly a smoke factory that winter. One idea developed to reduce the smoke was: The suction pipe to the pipe which ran to outdoors was broken and a Y let in; a branch was run to the end of the breeching so that a mixture of cold air and flue gases could be obtained. This mixture supplied under the grates resulted in a great diminution in black smoke. The amount of flue gases drawn in was regulated by a damper in the Y. On the whole the idea worked very well, and that boiler was in commission all winter.

As the work of bricking up the new No. 1 boiler proceded it was discovered that the stoker of No. 2 boiler would project into the brickwork of No. 1, so before the bricklayers had got much work done the stoker on No. 2 had to be dismantled and grates put under the boiler instead. So one week-end this had to be done, Saturday afternoon and night, Sunday and Sunday night the work went on. On Monday morning the new grates were in and the boiler under steam. No. 1 had to carry the whole load during that time. Very fortunately for us the weather was mild that week-end.

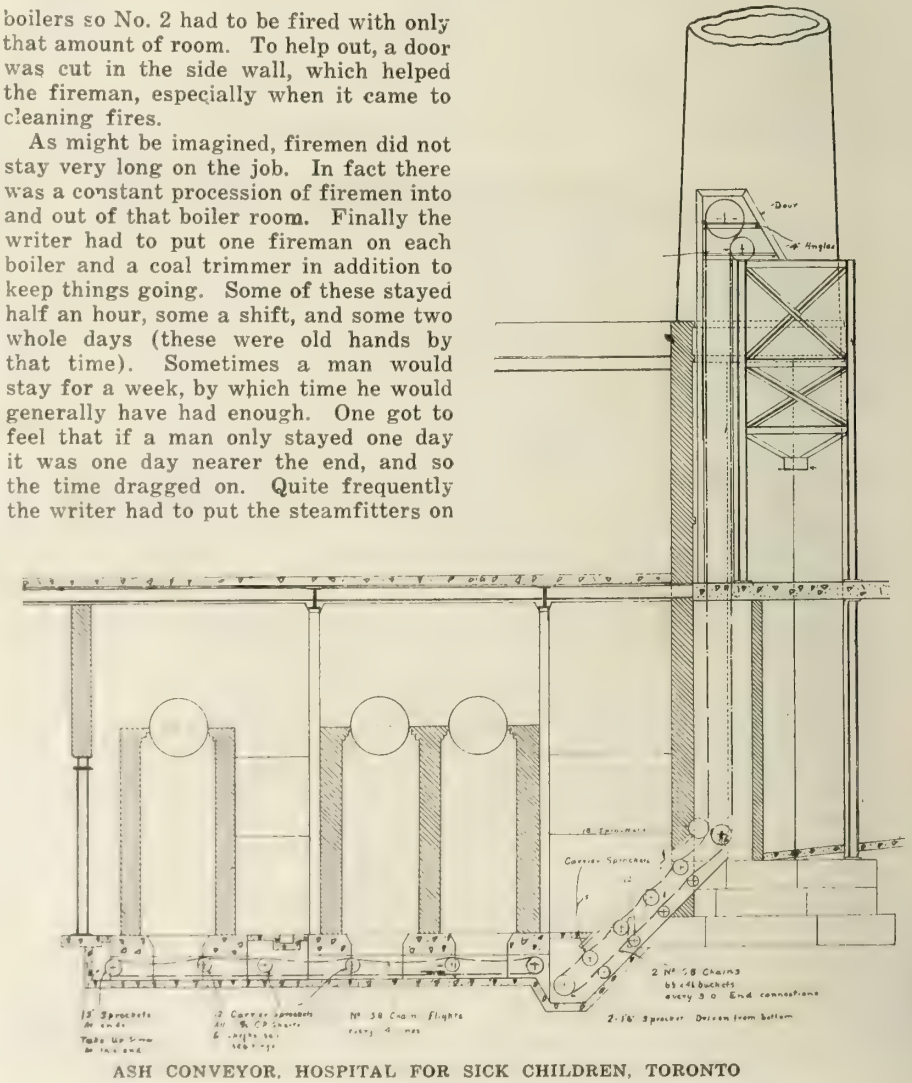
The new No. 1 boiler wall came about 4 ft. from the front wall of the other boilers so No. 2 had to be fired with only that amount of room. To help out, a door was cut in the side wall, which helped the fireman, especially when it came to cleaning fires.

As might be imagined, firemen did not stay very long on the job. In fact there was a constant procession of firemen into and out of that boiler room. Finally the writer had to put one fireman on each boiler and a coal trimmer in addition to keep things going. Some of these stayed half an hour, some a shift, and some two whole days (these were old hands by that time). Sometimes a man would stay for a week, by which time he would generally have had enough. One got to feel that if a man only stayed one day it was one day nearer the end, and so the time dragged on. Quite frequently the writer had to put the steamfitters on the boiler fires, which of course raised the cost of the job, besides holding it back considerably.

Whilst the old No. 3 boiler, now the new No. 1, was being rebuilt, which, by the way, was done by a local boiler maker (the makers being too busy to spare an erector) the ground under the old breeching was excavated and the north wall of the building underpinned. This underpinning helped considerably to boost the price of the job.

Where the No. 3 boiler had been was also dug out and the west wall underpinned and preparations made for building a new breeching. This is made of concrete, in the proportions 1-2-3, using cinders instead of gravel or broken stone. The inside measurements of the breeching are 6 ft. 3 in. wide by 5 ft. high, giving an area of over 31 sq. ft. as against 18 sq. ft. area of the old breeching. This was to allow for the increased length and a right angle bend.

The bottom of the breeching was carried on 7 in. I beams built into the building wall and into the boiler walls on the other end. The bottom was further reinforced with ¾ in. square twisted steel. The side walls of the breeching are 6 in. concrete with ¾ in. reinforcing. The top is 5 in. concrete, also reinforced. The concrete had to be run at two operations. The bottom forms were built and the



ASH CONVEYOR, HOSPITAL FOR SICK CHILDREN, TORONTO

concrete bottom 7 in. thick was run all in one piece. The sides and top forms were built up and the whole then run together, the men working day and night to make it one solid run without a break. Spaces were left in the walls of the breeching for No. 2 and No. 3 boilers, these spaces being built up with dry brick and then plastered over. The whole weight of the breeching was carried on a framing until the boilers were built up to it. which was a matter of three or four months.

In order to get as much of the breeching as possible in one piece and still keep the old one in service, the old one was cut off with a dry wall close to No. 2 boiler damper and the concrete run up to and joining the old breeching wall, which was of brick.

A manhole was left on the top of the new breeching for removing forms and rubbish. As soon as the building of the new breeching commenced the side door on No. 2 boiler was shut off, which made things increasingly difficult, especially round this No. 2 boiler, so that the boiler on forced draft was called upon to furnish most of the steam.

By the time the breeching was built the brickwork on the new No. 1 boiler was begun. If the place was cramped before, it was crowded out now, what with six or eight bricklayers and their boards for three different kinds of mortar (lime and cement, mortar, fireclay, and the special cement for Nonpareil brick),two or three laborers, two firemen and a trimmer, to say nothing of steamfitters, there was scarcely room to move. The drawings show a scant two feet of room between boiler and the engine room between the boiler and the engine room wall, and there was not more than four feet of room on the north side, and in this four feet coal had to be wheeled through and No. 2 boiler fired.

The lower six courses of brick were red or grey stock brick laid in cement mortar, according to the boilermaker's specifications, which were followed throughout, with the exception of using Armstrong Nonpareil insulating brick instead of one thickness of red brick. The bricks from the old setting were used as far as possible.

The boiler has 18 in. side walls and 14 in. back wall. The firebrick lining in the firebox is 9 in. thick laid in fireclay dipped, and the brick is laid, 1 course headers to three courses stretchers.

The lining in the first pass is 4½ in. thick, laid in a similar manner to the firebox. The firebrick is bonded into the red brick with firebrick headers, and the Nonpareil brick into the red brick, with red brick headers. Apart from the firebox, the boiler brickwork is laid 1 course headers to 4 courses stretchers. The use of Nonpareil brick has been justified by the low temperatures obtained on the brickwork of the boilers. With the boilers under full load and a firebox temperature of about 2,300° to 2,500° Fahr., judging by the color of the fire, one can bear to place one's hand on the brickwork and a thermometer shows a temperature of 150° Fahr. when placed on the brickwork for ten minutes.

As soon as the brickwork was safe to work on, the boiler was connected up for service. A 3 in. Davis non-return valve was placed on the front safety valve nozzle and a temporary line was connected to the high-pressure services. The back safety valve nozzle was blanked with a valve as this outlet was intended for use as the new main steam outlet. One side of the permanent feed main was placed in position as quickly as possible and the boiler filled and the brickwork dried out. One set of the herringbone grates were placed under this boiler temporarily and a slow fire lighted, after the new breeching had been cleaned and the dry wall knocked out.

By using the temporary gates about a week's time was saved as the stoker was rebuilt as the boiler was drying. Just at this time there was nowhere to place the motor to drive the stoker so the motor was placed on the gallery which runs around the boiler room and clamped down to the grating. A counter-shaft was hung under the grating and the stoker was running in about two hours after the work of placing the motor was started. There was some difficulty encountered after starting up this boiler. The local boilermaker, in spite of repeated instructions, managed to get in the baffle brick without fireclay, and the bricklayers left room below the baffle on the first pass to allow any nicely-heated gases a short straight cut to the stack, so that the Venturi meter only registered about 3,000 lbs. per hour. So the first Sunday that boiler had to be shut down again and the baffles made good. Neither boilermaker nor bricklayer are very likely to make that same mistake again.

Historical Development of the Steam Turbine—II

The Second Installment of a Series Dealing With Development of the Turbine—Growth in Size of Turbo-Generator Units in Recent Years—Compounding Adopted

THE past two decades have seen a growth in the size and economy of steam turbines beyond the most optimistic expectation of twenty years ago, as is shown graphically in Figs. 4, 5 and 6. The types of machines which represent the various stages in this development are illustrated and their performances are given in the following discussion:

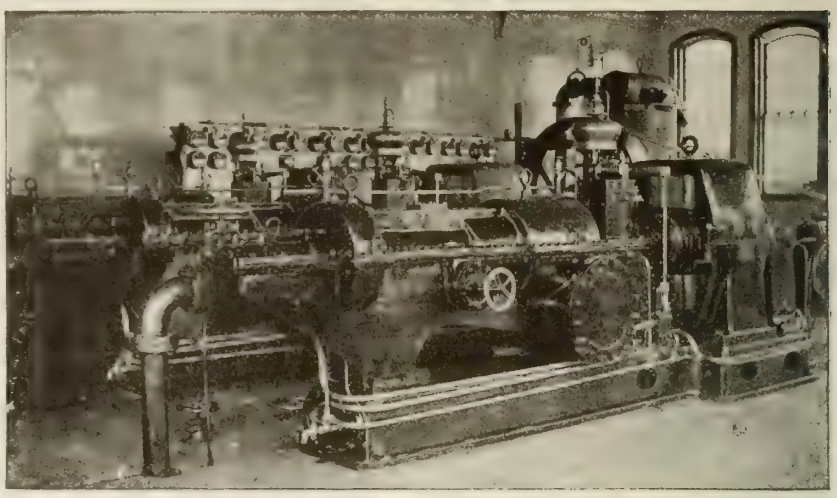

FIG. 11.—400-K.W. TURBINES INSTALLED 1899

1899

The 400 kilowatt 3,600 r.p.m. turbines, driving revolving armature, 440-volt generators shown in Fig. 11 were installed at the plant of the Westinghouse Air-brake Company. These turbines are still in service. Sixty-six machines of this size were sold.

1900

The 2,000 kilowatt turbine for the Hartford Electric Light Company shown in Fig. 12 was shipped in 1900. This turbine was of the straight Parsons single-cylinder construction and was designed to operate at 1,200 r.p.m.

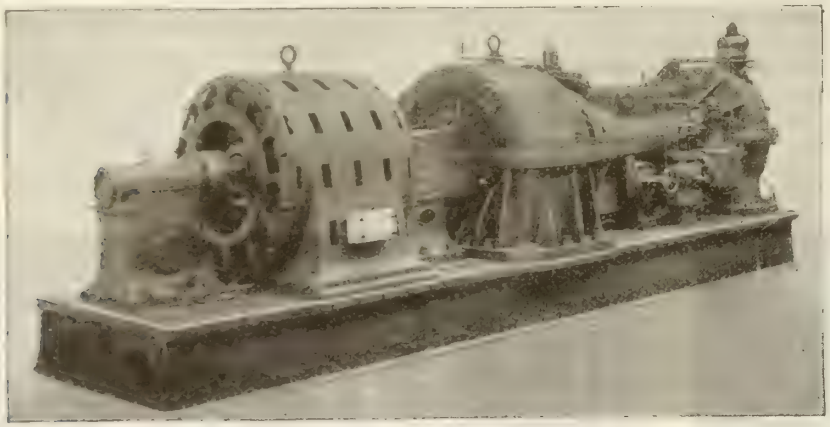

FIG. 12.—2,000 K.W. UNIT

1903

The 1,000 and 1,500 kilowatt two-cylinder machines arranged in tandem, shown in Fig 13, are of the straight Parsons design. Sixteen of these turbines were built.

1904

The single-cylinder machines of 1,000 kilowatt rating were built of straight Parsons design, the turbine as shown in Fig. 14 being operated either at 1,500 or 1,800 r.p.m. One hundred and twenty-nine of these turbines were sold in this year.

1905

Some large machines sensible of being given a normal rating of either 5,500 or 7,500 kilowatts were shipped in 1905. These were regarded at the time as of unprecedented capacity. They operated at 750 r.p.m., and were also of Parsons design, as shown in Fig. 15. Fourteen of these machines were built. Twelve of these are still in serviceable operation.

1905 to 1909

Between these years a very large number of straight re-action turbines were built of similar type to those described under 1903, varying in capacity from normal ratings of 300 kilowatts to normal ratings of 3,000 kilowatts, speeds varying from 3,600 to 1,200 r.p.m., and others at 7,500 kilowatt capacity at 750 r.p.m.

1909

Improvement in generator construction permitted increased capacities at a given speed as it was then considered undesirable to materially increase the blade speeds. A feature was developed for providing the turbine with low-

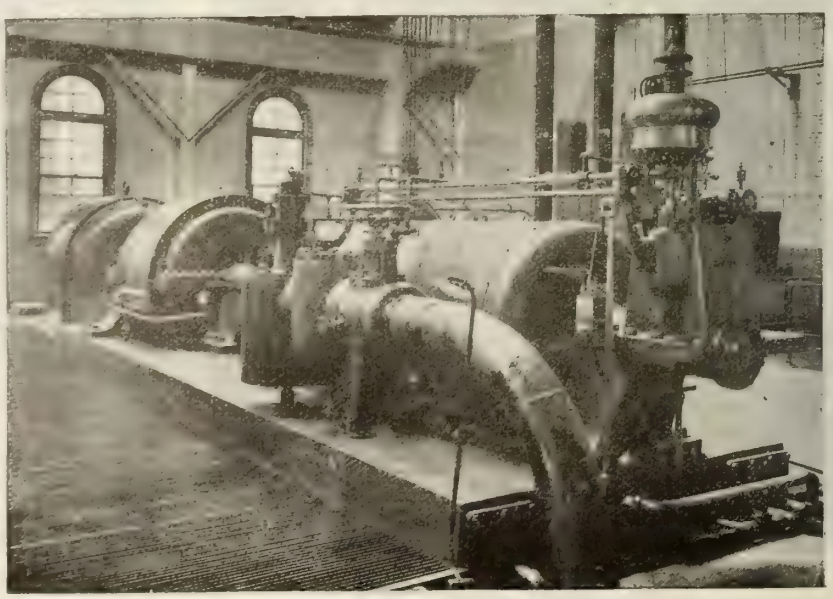

FIG. 13.—TANDEM COMOUND TURBINE

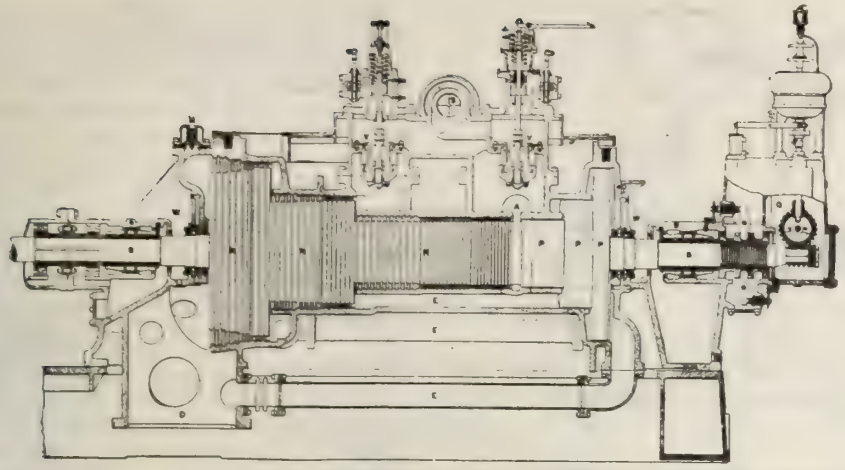

FIG. 14.—1,000 K.W. TURBINE OF PARSONS DESIGN

pressure elements of double-flow construction, thus doubling the capacity of those elements and replacing the first barrel of Parsons blading in the older design machines, whose dimensions were small and consequently subject to large leakage losses, by an impulse element, producing what is now known as a single-double flow turbine.

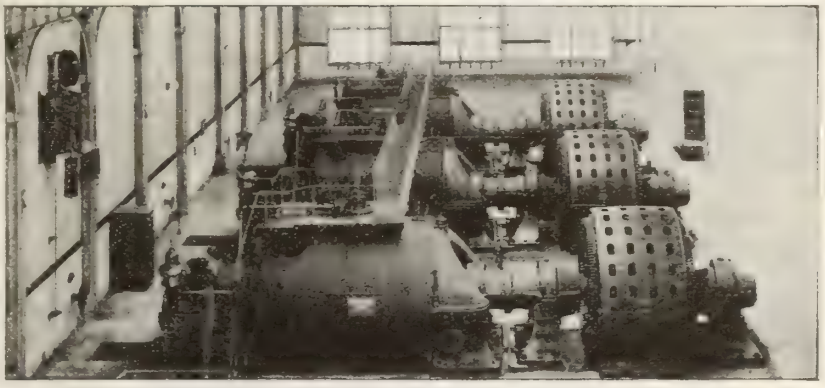

FIG. 15.—A 1905 INSTALLATION

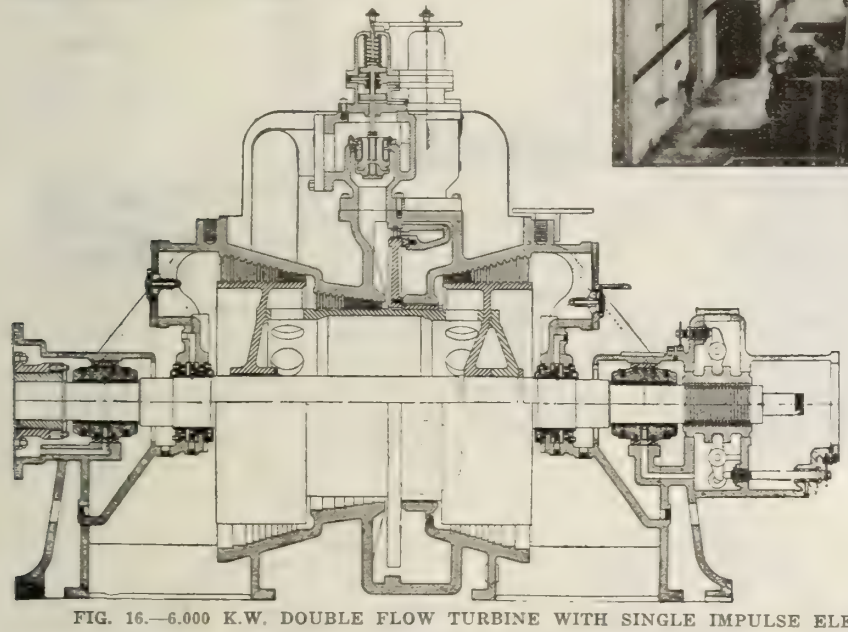

FIG. 16.—6.000 K.W. DOUBLE FLOW TURBINE WITH SINGLE IMPULSE ELEMENT

During this year there were shipped a number of 6.000 kilowatt, 1,500 r.p.m. normal rated machines as shown in Fig. 16. At the same time some 10,000 kilowatt, 750 r.p.m. machines of the same construction were built and are shown in Fig. 17. Also during this year there was shipped a 1,500 r.p.m., 10,000 kilowatt maximum rated machine to the Metropolitan Street Railway Company

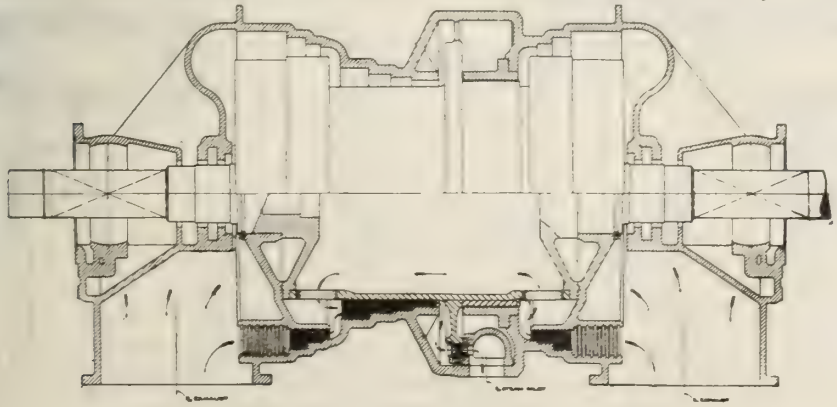

FIG. 17.—10,000 K.W. MACHINE OF SIMILAR CONSTRUCTION

of Kansas City, of single-double-flow construction. With a load of 8,551 kilowatts at 166.5 pounds, gauge steam pressure at 75.4 degrees F. superheat and a vacuum of 28.73 inches mercury, the steam consumption of this turbine was 14.50 pounds per kilowatt-hour, and its efficiency ratio was 65.0.

In the same year an epoch-making machine was shipped to the City Electric Company of San Francisco, of 10,000 kilowatt normal rated capacity, 15,000 kilowatt maximum, at 1,800 r.p.m. This machine, as shown in Fig. 18, was of double-flow construction, except that the impulse element only was single-flow, all of the re-action blading being double-flow.

1910

A 2,000 kilowatt normal rated, 3,000 kilowatt maximum machine was developed of precisely similar design to the 10,000 kilowatt turbine, except that it was arranged to operate at 3,600 r.p.m. In the absence of authentic tests its performance at 2,000 kilowatts is stated to be 15.4 pounds per kilowatt-hour, giving an efficiency ratio of 63.5, with 175 pounds gauge steam pressure, 100 degrees F. superheat and 28.0 inches mercury vacuum.

1911

Some bleeded turbines as shown in Fig. 21 were developed of 750 to 1,500 kilowatt capacity for industrial plants where heating was required for some industrial process, also for small communities which required exhaust steam in the winter time for district heating, the turbine operating completely condensing in the summer. These turbines automatically maintain the desired pressure in the heating system, and that which is not required for heating purposes passes through the low-pressure turbine elements to the condenser.

1912

A 3,500 kilowatt normal rated, 4,500 kilowatt maximum, double-flow turbine as shown in Fig. 20 was shipped in this year, the impulse element only being single-flow, designed to operate at 3,600 r.p.m., in which blade speeds as high as 500 feet per second were employed. In the absence of authentic tests their performance is stated to be that shown in connection with Fig. 20. In this year

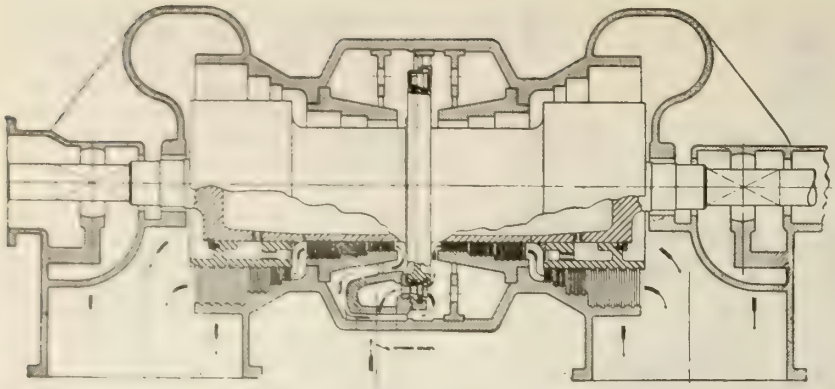

FIG. 18. 15,000 K.W. TURBINE, DOUBLE REACTION BLADING AND SINGLE IMPULSE ELEMENT

two of the largest geared direct-current units of 3,750 kilowatt capacity were shipped. These turbines, which were shown in Fig. 1, operate non-condensing against 20 pounds back pressure, the gear reduction being from 1,800 to 180 r.p.m. The operation of these gears and turbines has been of a most satisfactory character.

1913

A 20,000 kilowatt maximum rated turbine operating at 1,500 r.p.m., as shown in Fig. 23, and a 15,000 kilowatt maximum turbine operating at 1,800 r.p.m. were developed of a design similar to the 3,600 r.p.m. turbine of Fig. 20. There were a large number of these built

1914

Some important machines of 30,000 kilowatt capacity were shipped to the Interborough Rapid Transit Company of New York City, in which the principle of so-called cross-compounding was introduced; the steam expansion being divided in two separate elements, each driving a separate generator. The high and low-pressure element respectively operating at different speeds, each at the nearest synchronous speed most suitable to the steam volume involved, as shown in Fig. 19. The advantage of cross-compounding is commended for the increased reliability thereby gained.

1915

Machines of 20,000 kilowatts maximum capacity, 25-cycles, 1,500 r.p.m., as shown in Fig. 22, having higher design co-efficients than those heretofore built for machines whose expansion was complete within a single cylinder, were shipped in 1915.

1916

A 60-cycle machine of 1,800 r.p.m., of similar design to the above was developed in 1916.

1917

During the year, 30,000 kilowatt machines of single-double-flow construction were shipped, having all-re-action blading, the complete expansion being carried out within a single cylinder, as shown in Fig. 25.

Another high efficiency machine of 35,000 kilowatt capacity has been shipped to the Commonwealth Edison Company of Chicago, the steam expansion being divided in two elements like those described under 1903, the cylinders being arranged tandem fashion, and driving one generator, as shown in Fig. 24. The first of these machines has been placed in successful operation during the year.

Some 40,000 and 45,000 kilowatt, 60-cycle, cross-compound machines, similar to the Interborough Rapid Transit Company's machines, have lately been put in service. The high-pressure element operates at 1,800 r.p.m., and the low-pressure at 1,200 r.p.m. There are also under construction 60,000 kilowatt turbines for both 25 and 60-cycle service, which are a further development of the compound principle, in that the turbine element will comprise one high-pressure and two low-pressure elements, the steam passing through the latter in parallel and each driving separate generators. Means are provided that, should the circuit-breaker open on any of these elements or should the unit be put out of service by means of the emergency stop, the remaining two units will continue operating, thus providing in a measure the economy commensurate with a very large unit with the flexibility of a number of smaller units.

It is expected that the new 35,000 kilowatt, 60-cycle, 1,200 r.p.m., tandem compound turbine with direct-connected exciter, with a load of 25,000 kilowatts

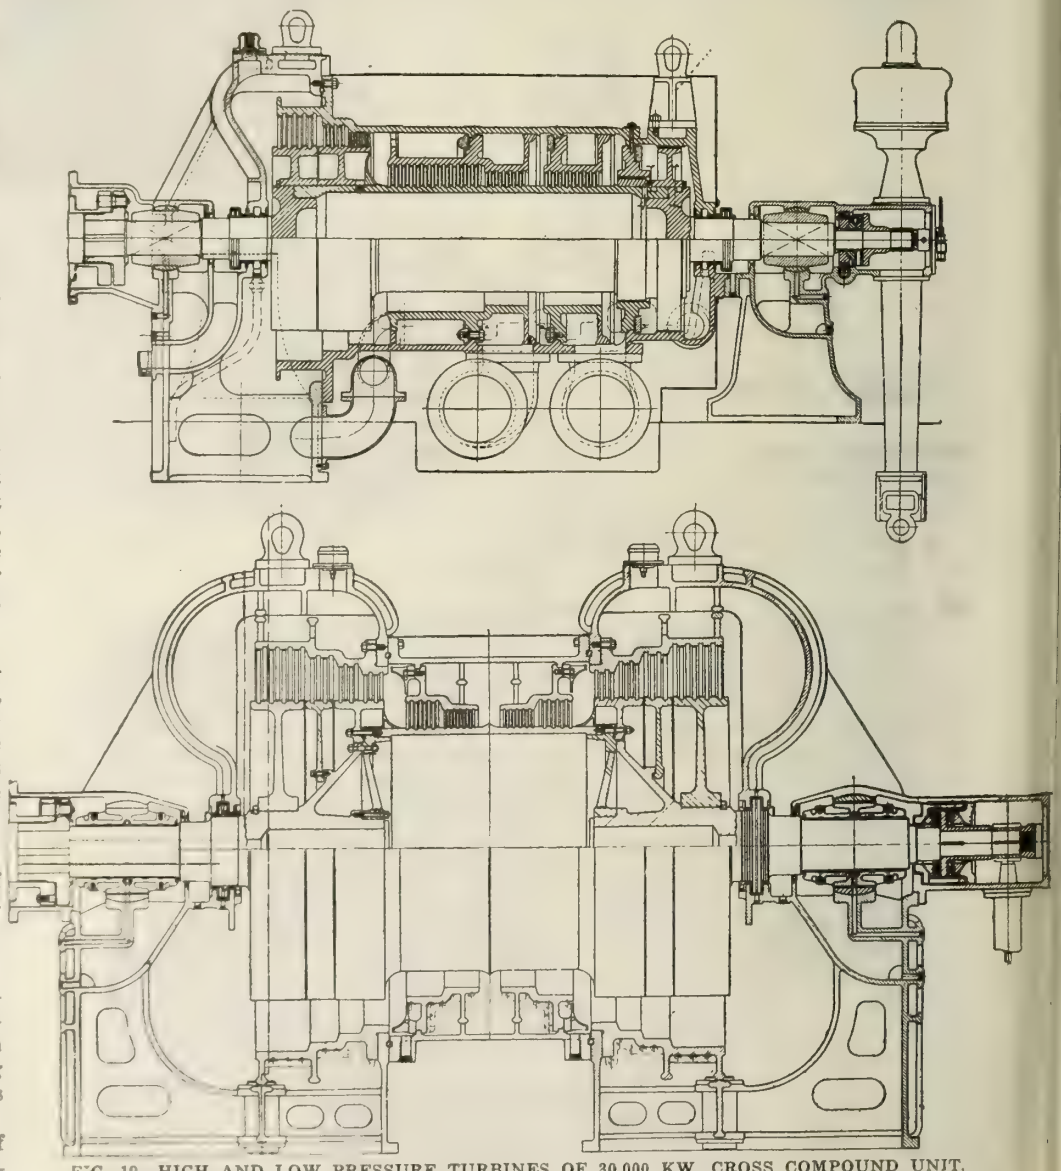

FIG. 19—HIGH AND LOW PRESSURE TURBINES OF 30,000 KW. CROSS COMPOUND UNIT.

at 85 per cent. power-factor, at 220 pounds, gauge steam pressure, 200 degrees F. superheat and a vacuum of 29 inches mercury, will have a steam consumption of 10.65 pounds per kilowatt-hour, and an efficiency ratio of 75.4.

With a load of 50,000 kilowatts at 275 pounds gauge steam pressure,, 200 degrees F. superheat and a vacuum of 28.5 inches mercury, the new 60,000 kilowatt, 60-cycle, 1,800 and 1,200 r.p.m., three-cylinder, cross-compound turbine at 85 per cent. power factor will have a steam consumption of 10.65 pounds per kilowatt-hour and an efficiency ratio of 76.2. Also the 60,000 kilowatt, 25-cycle, 1,500 r.p.m., three-cylinder, cross-compound turbine at 100 per cent. power factor with a load of 40,000 kilowatts at 205 pounds, gauge steam pressure, at 150 degrees . superheat and a vacuum of 29 inches of mercury, will give a steam consumption of 10.75 pounds per kilowatt-hour and an efficiency ratio of 77.7.

In comparing the foregoing performances, cognizance must be given to the fact that the efficiency ratio cannot be used as a direct comparison, for the same turbine will give a higher efficiency ratio with higher superheat. This emphasizes the quite remarkable performance of the earliest machine. The efficiency ratios quoted in the foregoing include generator losses. It may be proper to explain that by efficiency ratio is meant the ratio of the energy actually obtained from an engine to that which is theoretically obtained by the adjabatic expansion of steam between the specified pressure and also temperature limits.

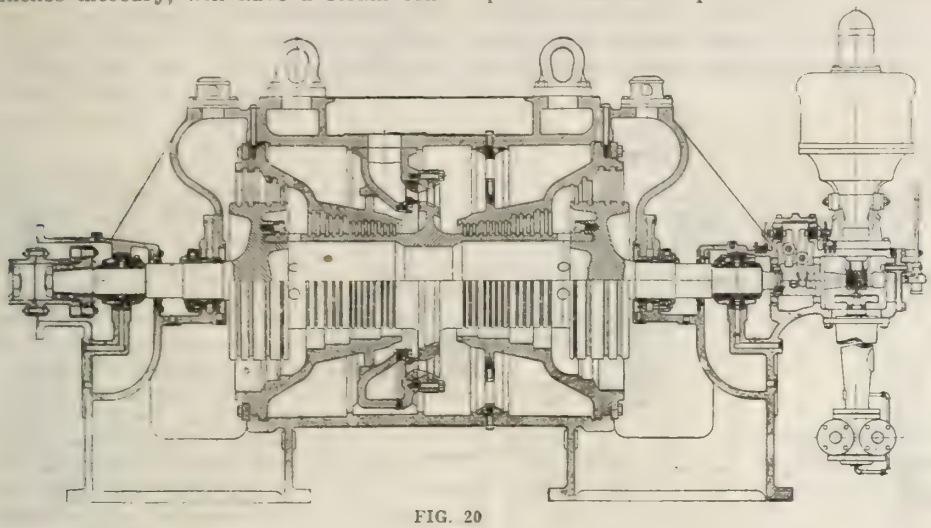

FIG. 20

It is interesting to record that owing to the changed condition of the merchant marine in the United States a large number of vessels are under construction in which geared turbines are being employed. The Westinghouse Company has built and has under contract steam turbine propelling machinery for two hundred and forty-four merchant ships with an aggregate horse-power capacity of 480,000. Four of the above have been to sea and proven eminently successful. In addition to the above the same company has built and has under contract turbine propelling machinery for fifty-six naval vessels aggregating 1,600,000 horse-power. In the case of 10,000 horse-power passenger ship trading in the Pacific, 22.8 per cent. gain in fuel consumption is experienced as compared with a sister ship having modern four cylinder three stage reciprocating engines.

Along with the improvements in turbine performances already discussed have been corresponding improvements in details which have materially increased the reliability of steam turbines. Some of these details, for example, the blading and governing systems, have in themselves gone through a process of development which will be reviewed briefly. (To be continued)

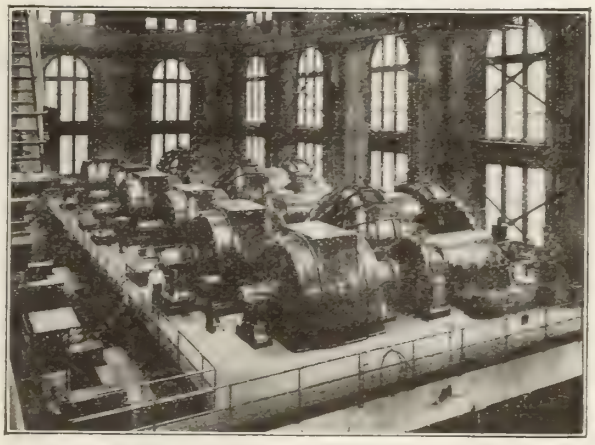

FIG. 24

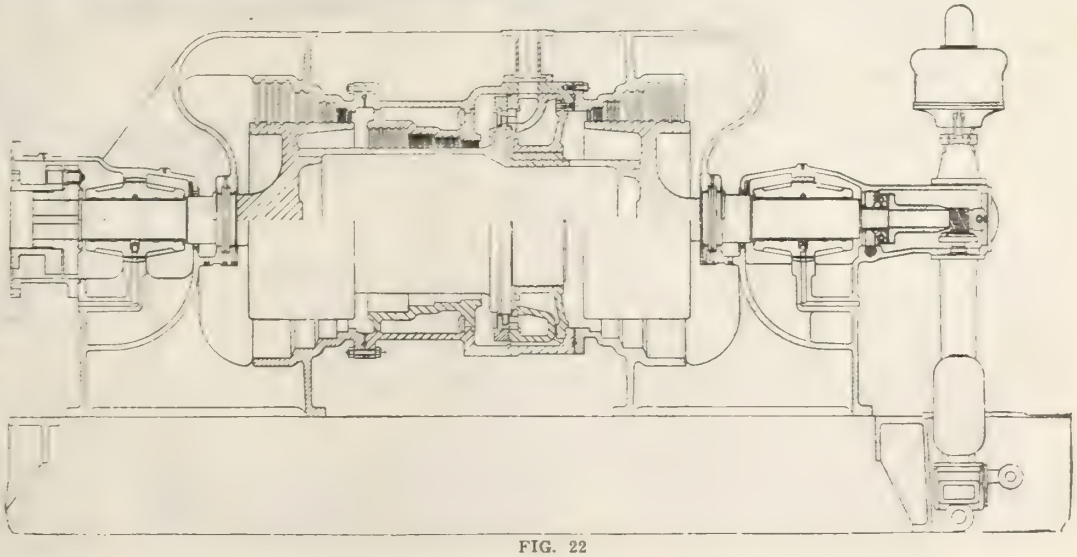

FIG. 22

LUBRICANT ECONOMY

By D. Street

One of the minor troubles in the mechanical business at the present moment, which is certain to become more acute as time advances, is that of lubrication. Oils, fats and greases, of whatever origin, do not increase and multiply. They grow scarcer and dearer. The troubles in this respect in enemy countries are their own, and it is certain that rolling stock of all kinds must be in a deplorable condition there owing to the blockade, and this matter alone is forcing the pace with regard to Rumania and Russia. Lubricants are as essential to the conduct of war and transport as food. With a shrinking tonnage available, importation must inevitably be restricted further still, and there is no natural supply of oil available in many countries. Tallow, lard, mineral oils, as well as those of vegetable origin, are all in like case. The shortage of edible fats has led to rationing these equably to the population, and practically the whole available supply of vegetable oils can be considered as withdrawn for food purposes in Great Britain.

Out of this shortage and scarcity arise several matters worth mention; the first of these exerts a natural check upon consumption; prices are rising steeply. The second matter is that relief in this particular cannot be expected; indeed, the conditions of scarcity will prevail after hostilities cease. Conservation of existing stocks therefore must be rigidly practised.

So far as possible all wastage should be avoided. In the normal shop quite half the expenditure upon lubricants is thrown away; every unit in the shop force should, as a point of honor, contrive to use as little oil as possible. For instance, the use of the oil can to drill a hole, or on any machining operation should be barred; it's up to the storekeeper to ration the supply with the strictest economy. The management should display in a conspicuous place warnings upon the matter, taking the percentage increase in cost and the need for rigid economy, of the national stocks.

Most moving mechanism can be efficiently lubricated with about half the considered normal amount. Where drip lubrication is in use a little careful investigation will show how to cut expenditure of lubrication. In deed and fact, without being parsimonious, and without grudging the needful supply, the drops per unit of time can in many instances be halved without danger of rise in temperature.

It was an experienced operating engineer who maintained from experiment that doing his own oiling round he cut oil bills 33 1-3 per cent. Bearings of common type, unprovided with drip trays, needing adjustment, and with surfaces in poor condition, require much more oil than those under the reverse conditions. To compensate and spin out the supply, and so save tonnage, every piece of greasy waste should be treated to recover the oil; a small centrifugal extractor and filter pays large dividends in a big works.

Care should be exercised over the oil can to see that this is in good shape and not leaky. One way in which the mechanical trades, and every man in association therewith, can help victory is to be sparing with the oil can. Owing to the fact that ball bearings need but one filling of grease, and this simply to exclude the grit, over a long period of time, the present high price of lubricants and the national need should instal these wherever possible.

A ball bearing will (dust excluded) run without lubricant at all, and present circumstances should make them more prominent than before. All grease and greasy material should be collected.

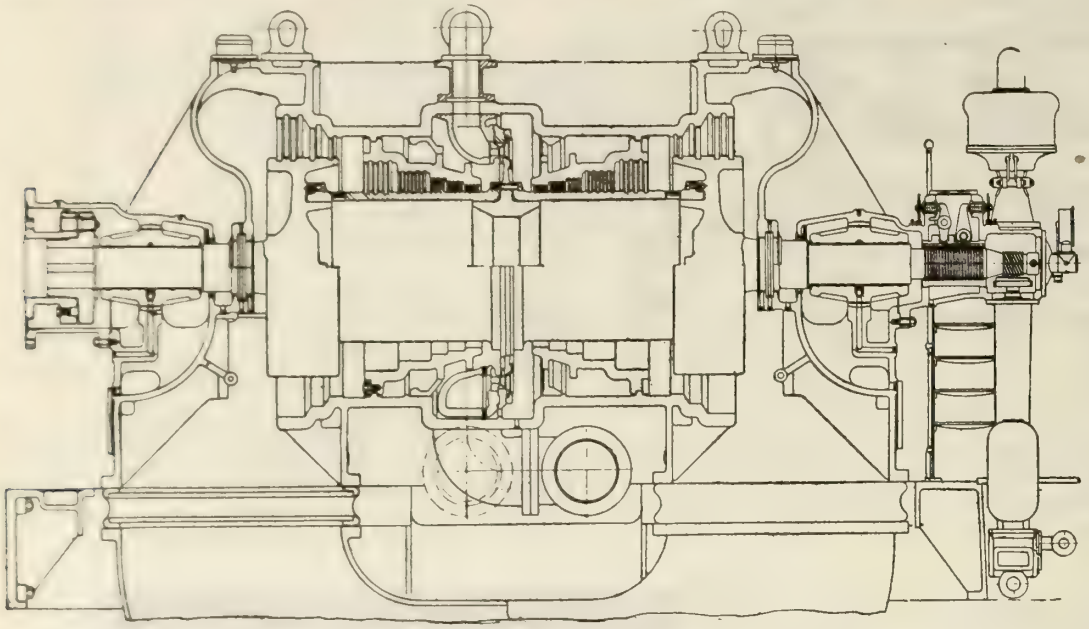

FIG. 23—20,000 KW. TURBINE, DESIGNED IN 1913

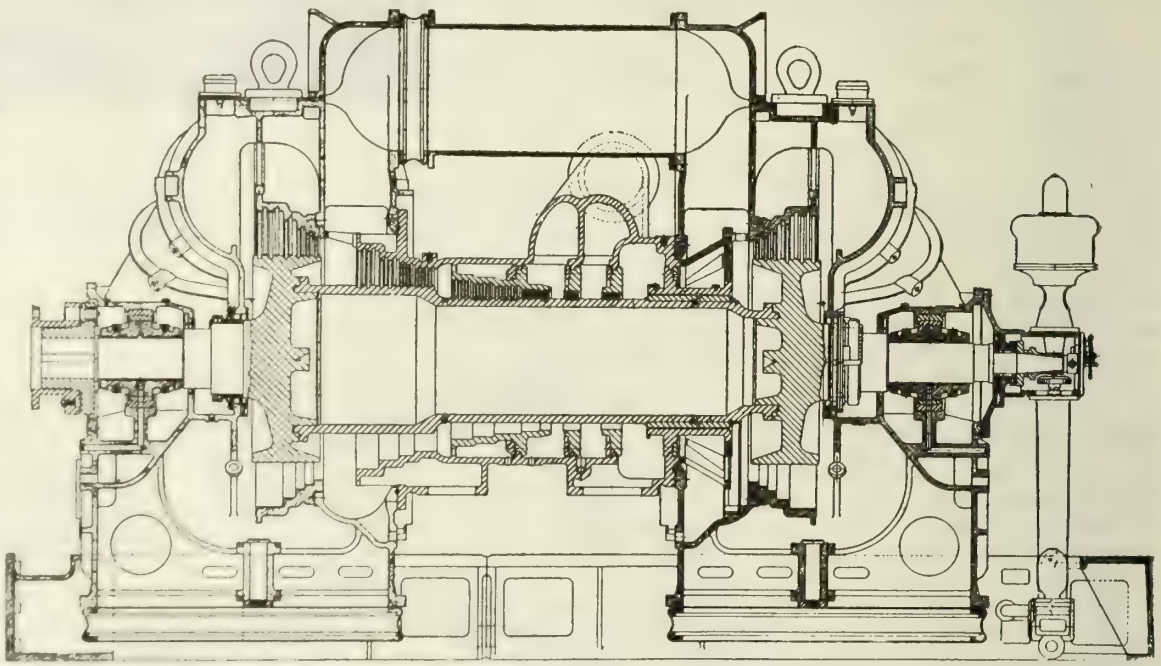

FIG. 24—TANDEM COMPOUND UNIT OF 35,000 KW. CAPACITY FOR THE COMMONWEALTH EDISON CO., CHICAGO

The Growth and History of Refrigeration

Refrigeration is All Essential in Maintaining Modern Civilization —Cities, Battleships, Armies in the Field, All Are Dependent For Their Food Supply on the Refrigerating Plant

By JAMES F. PATTON

HOW many of us realize the enormous part mechanical refrigeration plays in modern civilization? When the price of meats soar high we usually condemn the "profiteer" packers, not considering the fact that a large per cent. of our population is herded together in the large cities, and progressive communities make no provision for the old-time butcher who killed his own cattle under unsanitary conditions, nor are they likely to do so. Without the packers and their wonderful system of mechanical refrigeration we would have no meats at all.

In carrying on the work of supplying hundreds of population centers with a highly perishable product in the kinds and quantities demanded, at the time needed, and in perfect condition, one Chicago packer has developed a chain of branch supply houses, nearly 400 in number, uses over 9,000 trained employees, 400 motor trucks, and over 7,000 refrigerator cars. The foundation on which the entire business is based being mechanical refrigeration.

Our boys "Over There" are absolutely dependent on the refrigerating systems as used on cars, storage houses, and on shipboard. The battleship uses such a system to keep the ammunition in a satisfactory condition, and the temperature of the shop in which the ammunition is produced is regulated by such a system.

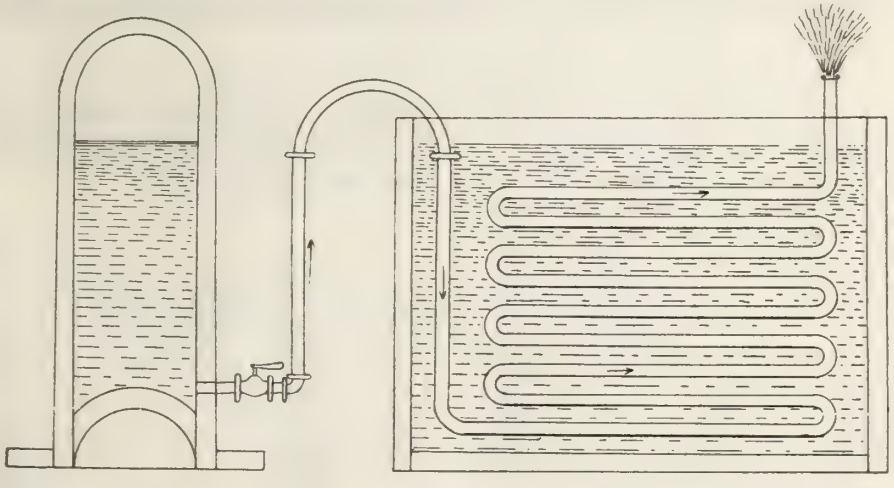

FIG. 1

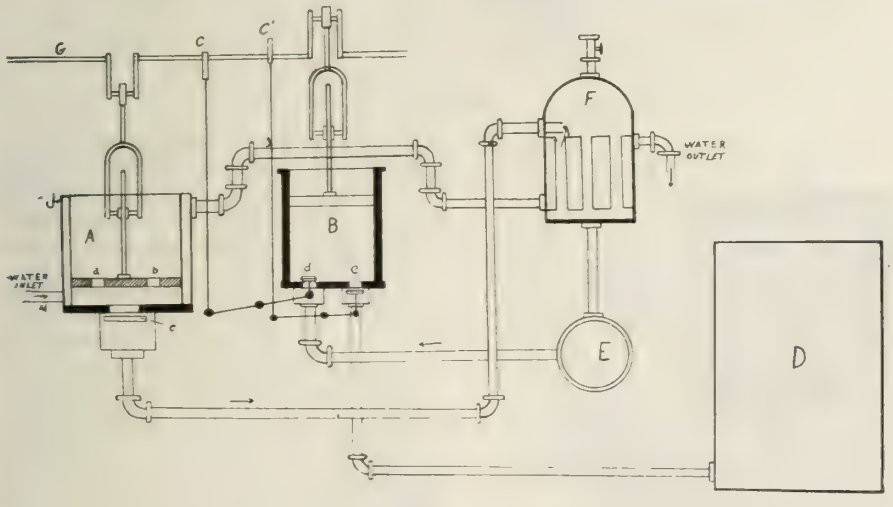

FIG. 2

Practically speaking, every modern food product to be found on the markets to-day has at some stage in its journey from producer to consumer, come under the influence of a refrigerating plant. The day is past when the producer was forced to dump his product on an overstocked market at an unsatisfactory price. Further, "seasons" do not affect the consumer because refrigerators have made it possible for us to purchase any particular delicacy we have set our hearts on at any time. The home, hospital, hotel, all are dependent upon refrigeration. The lady of means puts her furs in cold storage, while the poor woman of the slums in the great cities is thankful for artificial ice, which can be bought where natural ice is out of the question. Refrigeration also plays an important part in our amusements. We enjoy the "movies" on a hot afternoon, because the air has been artificially cooled, and even when the temperature it 102° Fahr., we can skate on smooth ice in the modern ice rink, if we desire to do so.

While the product of refrigerating machines is well known to all, and every housewife knows how much it costs to fill the lamily ice box, yet few of those who use the product know how it is produced. There is a natural state for all matter. Under the ordinary conditions, a liquid tends to remain a liquid, or a gas to remain a gas. A change in state is accompanied by change in temperature. It takes heat to melt iron, and when this iron solidifies, it gives out this heat again. Put some ether on your hand, a feeling of cold results. The ether was naturally a gas, and in its return from the liquid form to its natural state, heat is absorbed. Figure I illustrates an early type of machine known as the compression system. This is the simplest possible form, and if volatile liquids could be obtained at nominal cost, no other apparatus would be necessary, but as such is not the case, some means must be had of catching the vapor and using it again. The liquid is allowed to flow through the pipe and expand into the atmosphere. This will cool the liquid surrounding the pipes.

In 1845 Dr. Gorrie invented the cold air ice machine, shown in Fig. II. We are all familiar with the process of changing heat into work, the steam engine and gas engine are examples. The process used by Dr. Gorrie was the exact reversal of this, the change of work into heat, but in such a way as to produce cold. The underlying principle of operation is the fact that the expansion of a gas will produce cold, or rather remove heat, because heat is energy, something which exists, and cold is the absence of this, so in a strict sense we cannot produce cold, we can only remove that which exists—the heat. You can easily prove this principle. Pump an auto tire by

rapidly working a hand pump. Put your hand on the cylinder of the pump, and note that it is hot. Now open the valve

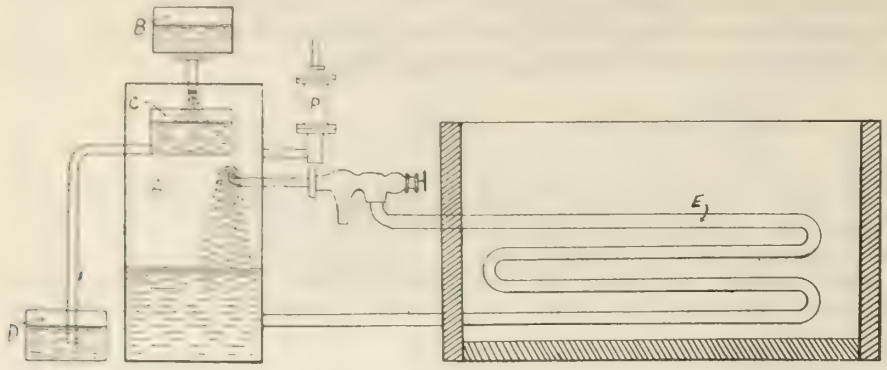

FIG. 3

in the tire and let the air out, feel it, and note that it is cold. The expansion of the compressed air has been accompanied by a decided cooling. Referring to Fig. I, we have a source of power represented by the line shaft G. This shaft furnishes power to drive the piston shown in the cylinder A. This piston has valves A-B, which close on the down stroke, and valve C, which opens on the down stroke. A downward stroke then compresses the air in the cylinder A. Valve C opens, and this air is forced through the pipe into the condenser F. The compression of the air in A generates heat, and in order to remove this the entire cylinder is water-jacketed, the water inlet being at M. This water flows through the upper pipe, through coils shown in the condenser F to the water outlet. The water serves two purposes; it helps to remove the heat generated by the compression in A and it also helps to further cool the air in F, for the air circulates between the coils. From the condenser the cooled air goes to the receiver E, from which there is a connection to the cylinder B. This is the expansion cylinder. The valves E and D are worked automatically by eccentrics, the valve D being closed during the compression stroke. The air

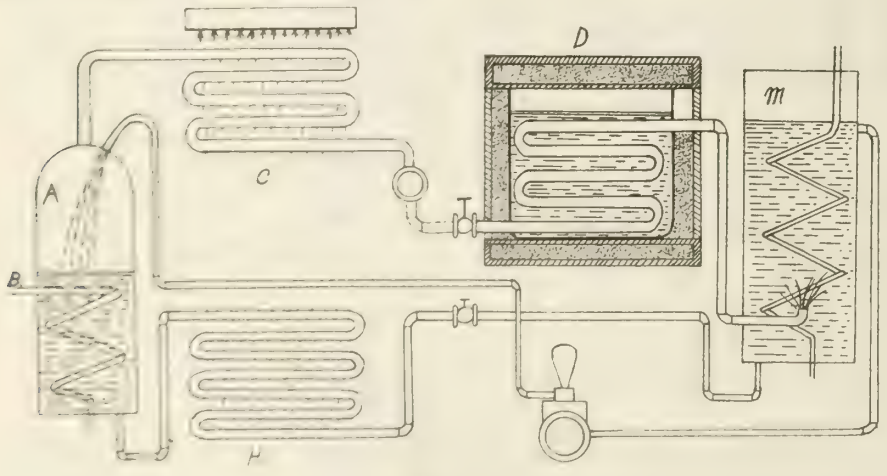

FIG. 5

in B expands, is further cooled by this expansion, and is discharged on down stroke of piston through the valve E to the refrigerator D, where it circulates in coils among the goods to be cooled, and is then returned to the machine or discharged. This type of machine has been largely used on shipboard owing to the entire absence of any obnoxious gases, but it is not efficient.

Nearly one hundred years before the cold air machine was perfected, Dr. Cullum applied the vacuum principle to ice-making. A solid substance may be changed to a liquid, or a liquid to a gas, but heat is needed to do the work. It takes heat to melt ice, and more heat to change the ice water to steam. In heating one pound of water 1 degree, 1 heat unit is used. This is the standard B.T.U. Now to change 1 pound of water at 212° to steam, 966 heat units are used. This is the reason why the sprinkling of the street on a hot day cools the atmosphere. The water evaporates, and the heat needed to cause this evaporation is taken from the air, pavement, and from the water itself.

In Fig. III an air pump P is used to produce a vacuum in tank A, which is partly full of water, which, as pressure is reduced, begins to evaporate. Vessel B contains sulphuric acid, which is permitted to spray into the smaller tank C, from which it is discharged to receiver D and repumped to reconcentrator not shown, then back to B. As this acid has an affinity for water it absorbs the water

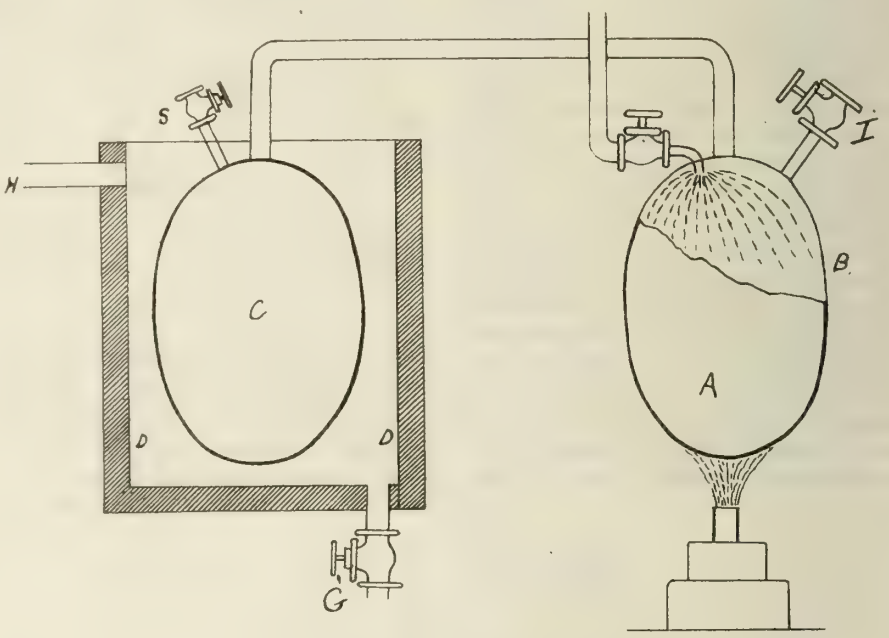

FIG. 4

vapor in chamber A. Fresh water is supplied through injector, which also assists in calculating the brine through the coils E in the refrigerator. This is an involved and costly process, not used to any extent commercially.

In Fig. IV we have two very strong iron vessels, which are connected by an iron pipe. In A we place a quantity of liquid ammonia. Under jar A we place a spirit lamp, the heat from which distills the liquid and the vapor passes to jar C. This jar is in a tank surrounded by cooling water. This water, being changed constantly and kept at a low temperature, forces the ammonia gas to condense in C. When the distillation is completed the lamp is removed, cooling water is allowed to flow over A, and the pressure is therefore reduced, which causes the liquid ammonia to vaporize and return to A, when it is reabsorbed by the water. As this ammonia evaporates it removes the heat from the liquid which surrounds B, and freezing is

accomplished. For many years following the discovery of this principle it was not used, as continuous operation could not be obtained. This was finally accomplished, however, and Fig. V shows the main parts of the modern absorption plant. Steam flows through coil B in tank A, thus raising the temperature of the ammonia solution, so that ammonia gas is driven off at a high pressure, going to the condenser C. The temperature is regulated so that it is always below the boiling point of water, consequently no water is evaporated.

Water flows over this, removing heat from the gas and condensing it. The gas passes through valve to coils in D, where the expansion of the gas removes heat from the brine or other liquid in the tank.

Liquid from the bottom of A flows through coil H, where it is cooled, to tank M, where it meets and absorbs the gas from D, the pump forcing the liquid back to A.

There are three processes in the modern plant: first, the gas must be reduced in volume by a compressor; second, the heat generated by this compression must be removed and gas reduced to a liquid; third, it must then be re-expanded so as to absorb additional heat. The can and plate systems are most used in ice making. In the former the insulated tanks contain brine, which is kept at a temperature considerably below the freezing point of water, evaporating coils being used. In this brine, galvanized iron cans are immersed. These contain the water to be frozen. In the plate system a hollow plate of boiler iron is immersed in a tank containing water to be frozen. The plate is filled with brine, which is cooled by evaporating coils. In the course of time layers of ice form on the sides of the plate.

Why Stokers Are Efficient—Smoke Prevention—Stokers and Laborer Types of Stokers—Chain Grate Stokers, Characteristics of—Instructions For Operation

By ROBT. JUNE

STOKER-FIRED furnaces have many advantages over hand firing, but where a stoker installation is contemplated there are many factors to be considered. It is true that the stokers if the coal to the fire automatically, but if the coal has first to be fed to the stoker hopper by hand its automatic advantage is lost. This is as true of the removal of ash from a stoker. In a general way it may be stated that a stoker installation is not advantageous except possibly for diminishing smoke, unless the automatic feature is carried to the handling of the coal and ash, as, where coal and ash handling apparatus is not installed there is no saving of labor. In large plants, however, stokers used in conjunction with modern methods of coal storage and coal and ash handling, make possible a large labor saving. In small plants the labor saving for stokers over hand-fired furnaces is negligible, and the expense of installation is no less proportionately than in large plants. Stokers are, therefore, advisable in small plants only where the saving in fuel will be large, or where the smoke question is important.

Interest on investment, repairs, depreciation and steam required for blast and stoker drive must all be considered. The up-keep cost will, in general, be higher than for hand-fired furnaces. Stokers. however, make possible the use of cheaper fuels with as high or higher economy than is obtainable under operating conditions in hand-fired furnaces with a better grade of fuel. The better efficiency obtainable with a good stoker is due to more even and continuous firing, as against the intermittent firing of the hand-fired furnaces; constant air supply, as against a variation in this supply, to meet varying furnace conditions in hand-fired furnaces and doing away, to a certain extent, with the necessity of working the fires.

Why Stokers are Efficient

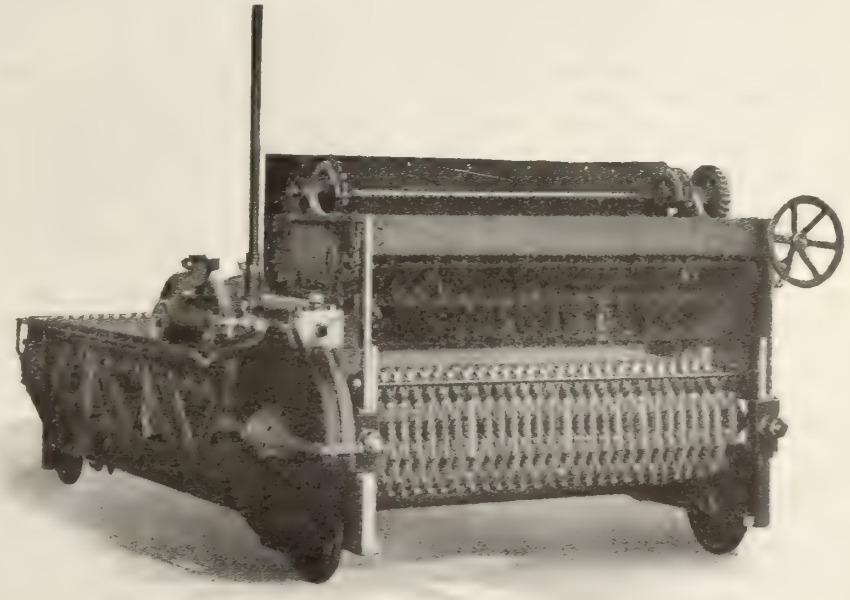
Mechanical stokers, as a class, are more effective in preventing smoke than hand-firing, for the reason that their continuous action is productive of uniform development of the volatile gases. Where stokers feed irregularly the effect is identical with hand firing, and it is necessary not only to employ an auxiliary mixing apparatus, but also to furnish at times an extra supply of air by means of fan or otherwise, to take care of the enormous volume of volatile gas evolved after a fresh charge of fuel is added. It follows that, for periods of light load, the stoker engine should be throttled down to the lowest possible speed rather than to be started and stopped intermittently.

The high efficiency of mechanical stokers is due to:

1. Uniformity of feed.
2. Proper proportion of air and combustible.
3. Absence of excessive air dilution. as when the fire doors are opened in connection with hand firing.
4. Self-cleaning grates.

There is a tendency in all stokers to cause a loss of some good fuel through siftings to the ash-pit, and suitable arrangements should be made to reclaim this.

Just as with hand firing, daily records are essential with any type of stoker if the most economical results are to be obtained. Only by frequent observation is it possible to determine the proper adjustment of air supply, depth of fire, and rate of feed. Don't leave the deter

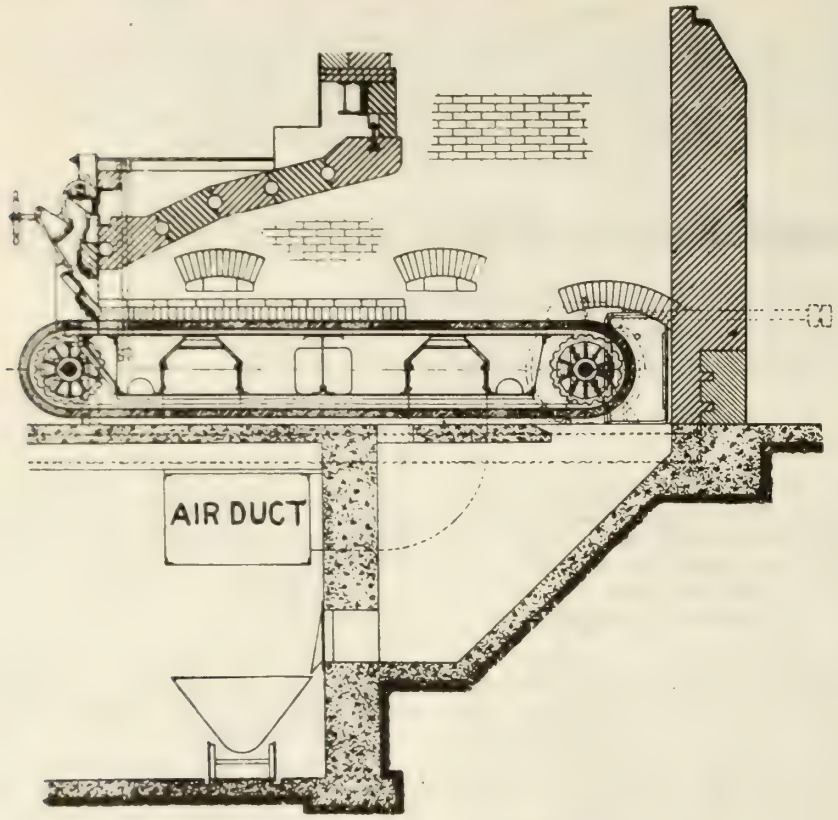


BABCOCK & WILCOX CHAIN GRATE STOKER

Editor's Note:—This is the sixth in a series of articles by Mr. June, on Power Plant Problems. Succeeding articles deal with principles of heat absorption, coal and ash handling equipment, storage of coal, abuse of steam, etc. Later articles sum up the best current practice in the business management of the power plant. The series is of timely interest and should prove of interest to our readers.

mination of these to your fireman's casual guess. The best engineer you can get—in or out of your plant—is the cheapest man to standardize your firing practice.

And once he has formulated standard practice don't think that all is done, and that you and he can go away and forget your stokers. Ten chances to one your boiler room crew is constantly shifting, and you have no guarantee that two succeeding shipments of coal will come from the same mine or that they will be of similar characteristics. Call your engineer back to check up methods and results of firing every week or two at first; later, his visits can be cut down to once a month if conditions warrant, but even with a stable, intelligent and willing boiler room crew and uniform coal, the monthly inspection should be rigidly adhered to. Stokers are often condemned by owners as inefficient and inferior to hand firing because no particular attention has been paid to them beyond keeping them supplied with coal.



COXE CHAIN GRATE STOKERS

Smoke and Stokers

The stoker is not a cure-all for the smoke evil. It is a decided alleviative in many cases, and an actual specific in many others, but to say that the installation of stokers will eliminate smoke in any and all circumstances, is to ignore evident facts.

There are any number of plants burning a wide variety of fuels in ordinary hand-fired furnaces, in extension furnaces, and on automatic stokers, that are operating under service conditions practically without smoke. We know from experience, however, that no plant will operate smokelessly under any and all conditions of service, nor is there a plant in which the degree of smokelessness does not depend upon the operating force.

When fires must be brought up quickly, operatives, in handling certain types of stokers, will use their slice bars freely to break up the green portion of the fire. In fact, when a load is suddenly thrown on a station, the steam pressure can often be maintained only in this way, and such use of the slice bar will cause smoke with the very best type of stoker. In a certain plant, using a highly volatile coal, and operating boilers equipped with ordinary hand-fired furnaces, extension hand-fired furnaces and stokers in which the boilers with the different types of furnaces were on separate stacks, a difference in smoke from the different types of furnaces was apparent at light loads, but when a heavy load was thrown on the plant all three stacks would smoke to the same extent, and it was impossible to judge which type of furnace was on one or the other of the stacks.

While it is absolutely true and should at all times be remembered that the question of smokelessness is largely one of degree, and dependent, to a much greater extent than is ordinarily appreciated, upon the handling of the fuel and the furnace by the operators, be these furnaces hand fired or automatically fired, it is a fact that the best results are obtained with a good stoker properly operated. The reason for this is that in practically all stoker installations there is, as compared with hand firing, a much longer time for combustion, the volatile gases as they are distilled being acted upon by ignition arches or other arches before they strike the heating surfaces. In many instances, too, stokers are installed with extension beyond the boiler front, which gives an added length of travel during which the gases are acted upon by the radiant heat from the ignition or supplementary arches, and here again the long travel gives time for the volatile gases to be properly consumed.

Stokers and Labor

In plants of 2,000 H.P. and over, the installation of mechanical stokers and coal conveyors effects a considerable saving in labor. With smaller plants, interest on investment, depreciation and other items of expense may make hand firing more desirable, although it should be noted that there are stoker plants of 200 H.P. which are considered a good investment by their owners.

A stoker of the self-cleaning, slow-running type, requires much less attention than a hand-fired furnace. With hand firing one fireman can effectively attend to the water, coal, and ashes of about 200 H.P., or handle coal for 500 H.P., whereas with good automatic stokers, equipped with overhead bunkers and down spouts, he can readily take care of 4,000 H.P.

Types of Stokers

There are three principal types of stokers—chain grate, overfeed and underfeed. In addition, there are several special types such as down draft and sprinkler. A clasification of the best-known American makes follows:

Chain Grates

Babcock & Wilcox; McKenzie; Lacelede-Christy; Green; Illinois; Westinghouse; Playford; Coxe.

Overfeed

Step Grates—Frontfeed: Roney; Wilkinson; Acme.

Step Grates—Sidefeed: Murphy; Detroit; Model.

Underfeed

Jones; Taylor; Westinghouse; American; Riley; Type "E".

Down Draft—Hawley.

Sprinkler—Swift; Vulcan.

Chain Grate Stokers

The standard type of chain grate is one of the most popular forms of automatic stokers for burning small sizes of high ash and free-burning bituminous coals (30 to 40 per cent. volatile matter, and 10 to 20 per cent. ash). It is also adapted to lignites and the very high ash coals of the West. With low ash coals at high rates of combustion the grate is apt to become overheated and breakage with attendant high maintenance may result.

The standard chain grate embodies a moving, endless chain of grate bars, mounted on a frame, with provision for the continuous and uniform feeding of coal into the furnace, the fuel and the grate moving together. As usually installed, the surface of the grate is horizontal, though in some designs it is given a slight incline toward the bridge wall. The operations of feeding the coal, carrying it through the progressive stages of combustion, removing the ashes

and clinkers, and maintaining a clean grate and free air supply are automatic. The driving mechanism consists of a gear train actuated by ratchet and pawls, the arms carrying the latter being given a reciprocating motion by an eccentric mounted on a line shaft. The latter may be driven by any type of engine or motor, and the speed of the grate regulated by varying the stroke of the arm carrying the pawls.

Fuel is fed into a hopper placed at the front end of the furnace and the depth of the fuel regulated by a guillotine damper. The front part of the furnace is provided with a flat or slightly inclined ignition arch, the function of which is obvious. The entire grate and driving mechanism is mounted on a permanent truck and may readily be removed from beneath the boilers. The thickness of the fire and the speed of the grate should be so regulated that when the fuel has reached the end of the grate it shall have been completely consumed and incandescent ashes only will be discharged into the pit.

With chain-grate stokers there may be leakage of air through the coal in the hoppers. In the earlier forms chain grates had an objectionable feature in that the admission of large amounts of excess air at the rear of the furnace through the grates was impossible. This objection has been largely overcome in recent models by the use of some such device as the bridge-wall water box and suitable dampers. A distinct advantage of chain grates over other types is that they can be withdrawn from the furnace for inspection or repairs without interfering in any way with the boiler setting.

Chain grate stokers in general produce less smoke than either overfeed or underfeed types, due to the fact that there are no cleaning periods necessary. Such periods occur with the latter types of stokers at intervals, depending upon the character of the fuel bed and the rate of combustion. With chain grate stokers the cleaning is continuous and automatic, and no periods occur when smoke will necessarily be produced.

This class of stoker is particularly successful in burning low grades of coal running high in ash and volatile matter, which can only be burned with difficulty on the other types.

The standard type of chain grate is not adapted to coking coals on account of the swelling and fusing action of the fuel under the ignition arch. The chain grate may be modified to burn this class of fuel by introducing inclined coking plates immediately under the front of the distillation. This agitation prevents the coal from fusing together, and by the time the fuel reaches the grate proper it no longer tends to coke.

Characteristics of Individual Chain Grate Stokers

The general characteristics of chain grate stokers have already been described. It may be of interest, however, to set down the individual characteristics of a representative number of chain grate stokers. It should be understood, of course, that the fact that a particular stoker is mentioned by name does not mean that the use of that stoker is recommended in preference to some other which is not mentioned.

Babcock and Wilcox Chain Grate Stoker

Coals best adapted for: Bituminous high volatile.

Draft: Natural or forced.

Arch construction: Parallel to grate, extending over two-thirds or more of grate surface.

Constructional features: Bridge wall fitted with water back to prevent grate bars from being burned. Construction excludes air at side of stoker. Structural channels between upper and lower layers of chain at rear of grate form a number of air baffles. Arrangement is such that a varying amount of air may be admitted to the rear of stoker to meet varying conditions of combustion. Any leakage of air at rear, prevented by bridge-wall water box, connected to circulation of boiler.

Operational features: With normal uniform load the type of ignition arch and setting insures smokeless combustion, but careful manipulation is necessary with rapidly fluctuating loads to prevent the formation of smoke.

Illinois Chain-Grate Stoker

Coals best adapted for: Illinois, Kansas, Iowa, Ohio, Arkansas, and other Middle-West coals, running 10 to 25 per cent. ash.

Draft: Natural or forced. Draft should be about .6 inch for high ash and .4 inch for low ash coals. At these drafts the stoker will average 42 lbs. of coal per sq. ft. of grate surface.

Arch construction: Flat suspended.

Constructional features: Hand operated dampers, built into place between upper and lower traveling links permit cutting off active chain-grate surface. Arrangement permits use of a "short fire" at light loads, without excessive air leakage.

Operational features: Fuel bed depth 5 to 6 inches. Rate of combustion varies proportionately to square foot of draft over fires.

Green Chain Grate Stoker

Coals best adapted for: Type "K" is built for long-flaming bituminous. Type "L" for coking bituminous coals.

Draft: Type "K" uses natural draft. Type "L" either natural or forced.

Arch construction: Ventilated flat suspended type.

Constructional features: Air leakage between chain and side walls prevented by adjustable flanges. In type "L" an inclined apron is provided to coke the fuel before it passes out onto the chain. A stationary water-back at times is used on the bridge-wall.

Operational features: Approximately 10 lbs. of coal per sq. ft. of grate surface can be burned for each .1 inch draft available over fire. .6 inch draft required to burn 50 lbs. per sq. ft. of grate surface per hour on type "K."

Playford Chain Grate Stoker

Coals best adapted for: Free-burning bituminous.

Draft: Natural. .15 to .2 inch over fire for normal loads. .2 to .4 inch over fire for loads up to 200 per cent.

Arch construction: Ventilated air-cooled flat type.

Constructional features: Air in-leakage in rear prevented by either fixed or movable water-back, or in some types of construction by a special air-cooled movable back. Stress laid by manufacturers on movable feature on ground that it permits holding fuel-bed on the grate until entirely consumed.

Operational features: By adjusting movable back large clinkers, if formed, can be dropped into the ash-pit. Backfiring of coal in the hopper prevented by water-cooling of entrance gate.

Leclede-Christy Chain Grate Stoker

Coals best adapted for: Illinois, middle Western bituminous; also Eastern long-flaming coals.

Draft: Natural.

Arch construction: Flat suspended type.

Constructional features: Air in-leakage at front and sides prevented by fuel gate being set against ignition arch and side frame construction, using ledge tile composed of special abrasive refractory. Leakage at rear prevented by baffles between upper and lower chain. Bridge-wall overhangs grate.

Westinghouse Chain Grate Stoker

Coals best adapted for: Long-flaming bituminous.

Draft: Natural. Minimum, .15 inch; maximum, .6 inch.

Arch construction: Flat suspended.

Constructional features: Air in-leakage in front and rear prevented by arrangement of frames and baffles.

Operational features: Combustion rates up to 50 lbs. of coal per sq, ft. of grate surface can be obtained.

Coxe Traveling Crane

Coals best adapted for: Anthracite and anthracite-rice, coke-breeze, as well as bituminous.

Draft: Forced only.

Arch construction: Upward inclination toward rear.

Operational features: 175 to 200 per cent. load can be carried with 3-inch pressure in the ash-pit.

Next month we will take up general instructions for chain grate operation and will also discuss the various types of overfeed and underfeed stokers.

On and after January 1, 1919, the Sanford Riley Stoker Company and Murphy Iron Works will combine their sales policies so as to render the greatest possible service to all customers.

Offices will be located at Worcester, Boston, New York, Philadelphia, Pittsburgh, Buffalo, Cleveland, Detroit, Cincinnati, Chicago, St. Paul. Each office will handle both the sales and service for the Riley Underfeed Stoker and the Murphy Automatic Furnace.

The engineers at the various offices will not only help customers to select the equipment most suitable for their conditions or requirements, but will also be at their service at all times to show them how to get the most out of their present equipment.

Electricity; Its Relation to Matter and Energy

Matter and All Forms of Energy May Be Said to Be Different Manifestations of Electricity—Atomic Theory Has Been Extended to Embrace the Ultimate Nature of Matter

By J. F. HEFFRON

THE MYSTERY OF MATTER AND ENERGY

THE aim of knowledge, the philosopher Hegel tells us, "is to divest the objective world of its strangeness, and to make us more at home in it." This idea has actuated the world's thinkers throughout the ages, and in connection with the problem under review we find that one of the chief ambitions of the early Greek speculators was to discover some one primitive substance or principle from which the contents of the universe had been developed. It may be said that at present this problem of the structure of matter has increased in importance, until it has become, among physicists, the problem of problems.

But a few years ago the actual accomplishment of providing a satisfactory answer to so difficult a problem seemed so improbable that we find so eminent an authority as Professor Tait saying that "the discovery of the ultimate nature of matter is probably beyond the range of human intelligence."

The rapid developments that have taken place in the scientific world during the last two decades have, however, opened to our view a new universe entirely unknown to the author of this quotation, and with this new acquisition of knowledge the problem of problems has received a fresh impetus which has carried it so far beyond the point reached in Tait's day, it would seem in the light of present events, that an achievement which seemed an improbability to a former generation has become a probability for the living present.

The assertion has frequently been made that the conception the physicist forms of the basic stuff out of which the universe is made is fundamentally the same as that of the earliest philosophers. In a certain sense this may be true, but in the mind of the early Greeks, this speculation had practically no basis of exact observation of nature and was not supported by a patient mastery of natural law. The Greeks made many brilliant suggestions, which it should have been the task of later generations to test and develop by actual observation of nature, but they slighted this necessary task and concerned themselves instead with mystical considerations which hung like a veil between the mind and nature. Hence their physical speculations were for the most part vague, and trifling.

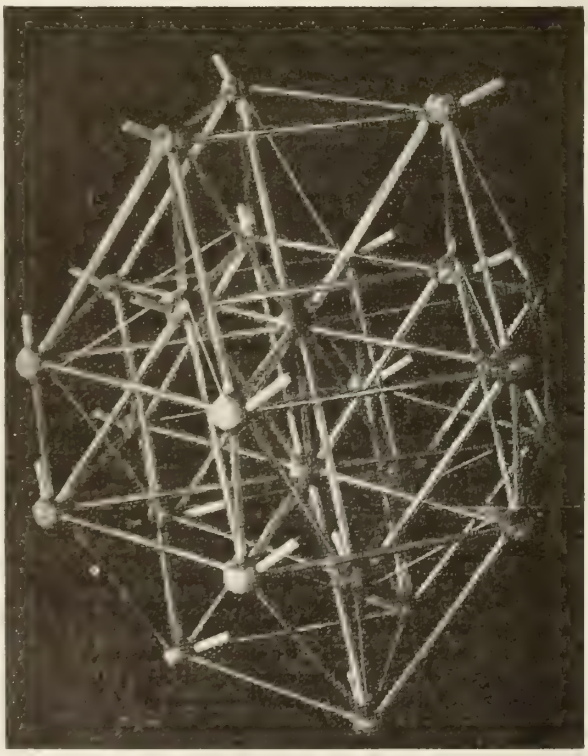


FIG. 2—DIAMOND MODEL

In our time each year sees science making additions to its already vast store of collected data, and it is to be expected that our ideas of the constitution of matter must present a very different aspect in the light of this new knowledge.

Aristotle's conception of the external world was that of a vast series of forms imposed upon a primitive stuff which underlay everything, being merely a sort of framework for various forms. The physicist of to-day, however, has learned the value of doubting an assertion until it has been checked and proven, and so continuously propose to himself the question whether there really is an "Urstoff" or "protyle" from which complex things have been evolved.

If we consider, for example, electricity, which appears a fairly concrete concrete thing, is it matter or merely a property of matter, or is it on the other hand "the" matter? Physics and chemistry as they exist to-day, can not be dissociated from it. Modern physical science can scarcely advance a pace without coming inti contact with some manifestation of electricity.

When, by a process of analysis, we follow matter back to its ultimate and so far irreducible expressions, we are ever brought face to face with clear evidences of electrical reactions. Less than twenty years ago the atom was looked upon generally as a simple piece of simple stuff. To-day, however, science is not so sure of the stability of the element, and although the atom will resist reduction beyond a certain point, science is impressed with its obvious duality. All atoms are regarded by science as having a definite structure. That is to say, every atom has a nucleus (or a circumference) of positive electricity, and a certain number of units of negative electricity—electrons. But since the electrons repel one another there seems to be proof that they cannot be arranged haphazardly in the element but must have a definite series of positions with regard to the positive nucleus, otherwise it would be impossible for them to preserve neutrality, viz., to maintain their respective positions. We see, therefore, that the simplest and smallest particle of matter of which we are at present able to conceive, possesses

a very real complexity of structure indeed.

Electrons

A discovery which has exercised a most profound influence on the development of physics in general and on our ideas of the structure of atoms in particular, was made in 1897 by Sir J. J. Thompson, when his experiments disclosed for the first time the existence of a new body having a mass of only 1/1845 part of that of the hydrogen atom. The lightest of the atoms composing the mass of the earth is that of hydrogen, and the heaviest that of uranium, which is 236.6 times heavier than the hydrogen atom, each of the atoms of the other elements weighing somewhere between these two comparatively narrow limits. This new body, at first called a corpuscle by its discoverer, and now known as an electron, is so very much lighter than the heretofore lightest known body, the hydrogen atom, that it could hardly be put in the same class with the atoms and called the atom of another element. The ratio of the mass of the hydrofien atom to that of the electron is 7.8 times as great as the ratio of the heaviest to the lightest atoms known.

In addition to this, a further unique characteristic distinguishes this body from the atoms of the elements. The electron is always associated with a negative charge of electricity, while the atoms of the elements in their ordinary condition in the earth appear to have no charge, or, if they have any, the negative is exactly neutralized by an equal amount of positive charge. A closer study of the atoms since the discovery of the electrons has made it probable that the atoms themselves are really made up of nearly equal amounts of positive and negative electrical charges, for ratio of the mass of the hydrogen atom under different conditions from the ordinary passive state and it is then found that they sometimes become charged with electricity. The electrical charge on an electron has been estimated in a variety of ways and measured with accuracy in others, and the remarkable fact has been established that in all these ways the charge upon one electron is equal to that upon any other, no matter where it is found.

Having established the constancy of weight of the individual atom and the constancy of charge on the electron, together with its small mass compared with the hydrogen atom, and coupling these facts with the observation that electrons appear to be universally present in all forms of matter, it has led naturally to the belief that the atoms themselves are structures, or assemblages of electrons grouped in different ways and in motion.

We have not the space in which to outline the very important consequences that followed in many directions from this fundamental discovery of the independent existence of the electron and its connection with matter. It was found by Kaufmann that the mass of the electron was not a constant, but increased with its speed, and from this result it was deduced that the electron was an atom of disembodied or condensed electricity occupying an exceedingly small volume whose mass was entirely electrical in origin.

The Constitution of Crystals

Science, we have stated, believes all atoms to possess a definite structure. As a striking example of what science has accomplished in opening up to our view a world incredibly minute, let us consider for a moment the form that matter sometimes assumes in the geometrical arrangement of the atoms in a crystal.

It is now well known that many substances under suitable conditions form crystals possessing a definite geometrical form. This arrangement of atoms in a crystal has been likened in plan to a thoroughly satisfactory garden city, and the form assumed is characteristic of the particular atoms or groups of atoms involved. Science has classified the great variety of crystal forms that are known and finds that each belongs to one or more of the 230 forms of point symmetry which are theoretically possible. It would seem that while considerations of symmetry are a sufficient guide to the classification of crystals, they offer no satisfactory explanation of the definite architecture of the crystals nor of the nature of the forces that cause the atoms or molecules to arrange themselves in such definite geometric patterns.

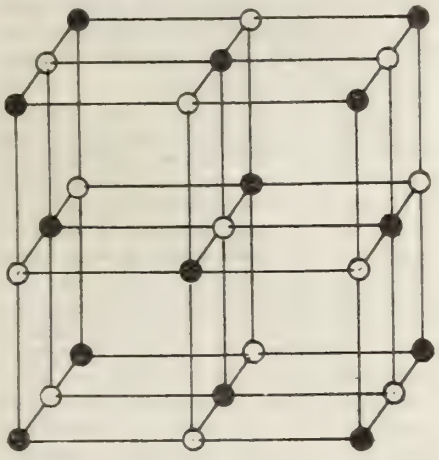

FIG. 1—MODEL OF ROCK SALT CRYSTAL

We are inevitably led to the conclusion that the atoms of the crystals are arranged according to a definite system, which is characteristic of the particular crystalline form, and the unit of structure is repeated indefinitely with continued growth of the crystal. In fact, had we no other evidence, the crystalline form of matter would itself point to the necessity of an atomic structure of all matter.

While many attempts have been made to explain the grouping of the atoms in a crystal little success has rewarded the labor expended in this connection, and it was only two years ago that Professor W. H. Bragg and his remarkable son, Doctor W. L. Bragg, applied a new and powerful method of attack on this problem.

The Braggs, father and son, have proven that the atoms in a crystal stand in regular order at definite distances apart and that these distances can be measured. They have been awarded the Nobel prize for physics in recognition of the importance of their joint work in this connection.

On account of the definite ordering of the atoms in a crystal it acts like an almost perfect optical grating. In this connection it might be well to point out that it is known that when Rontgen—X rays—are passed through a crystal, definite interference patterns can be observed. This of course shows that Rontgen rays must consist of the very short transverse waves akin to those of light. The Braggs have shown that the reflection, or rather diffraction, of Rontgen rays incident on the face of a crystal, afford a very simple method of determining the wave length of the bright lines generally present in an X-ray spectrum. By a study of the position and intensity of the spectra in different orders thrown on the crystal, it is possible to examine in detail the structure of the crystal, and to deduce the grating space, i.e., the distance between successive planes of atoms.

The subject, however, is so large and the discovery of this method of investigation so recent, that so far only a few of the typical crystals have been examined, but in all these cases we are able to obtain most positive evidence of the grouping of the atoms in the crystals. The results indicate that the atom and not the molecule is the unit of the crystal structure.

In Fig. 1 we have an illustration of the arrangement of the atoms in a rock salt (Na Cl) crystal as deduced by the Braggs. The sodium atoms are marked by little black spheres, the chlorine atoms by white spheres. It must be understood of course that the diagram is not drawn to scale since an attempt to accomplish this, owing to the relatively vast distances between the atoms would be almost impossible. The simplicity, however, of the crystal architecture is obvious, for all the atoms are equidistant. The structure of the diamond is slightly more complicated, but is one of great interest, since all the atoms in the diamond are of one kind, carbon. In the case of the diamond the atoms are all equidistant, but the general arrangement differs markedly from that of rock salt as may be observed in Fig. 2.

Having discovered a method by which we may determine the arrangement and distances apart of the atoms in a crystal, the next step will be to examine the intensity and type of the forces which are brought into play to keep the atoms in a state of equilibrium and relatively fixed in their places. The atoms are able to move to and fro about their position of equilibrium, and this is indicated by the effect of lowering the temperature of the crystal, for the intensity of the diffraction spectra increases as the amplitude of motion of the atom diminishes. The sharpness of the diffraction spectra, Rutherford tells us, suggests that the atoms are not only arranged at definite distances from one another, but that each atom is orientated in a definite position with regard to its neighbor.

Are Electricity and Matter One?

We have seen that in recent years methods have been developed for determining with precision certain attributes of any atom of matter. As a result of these investigations into the constitution of atomic structure it would appear that to-day science has reached the point where it inclines to the view that electricity and matter, together with the electron itself, have become one and the same thing.

Professor W. C. McLewis, of the University of Liverpool (England) in supporting this view, tells us that it has long been known that any substance which has been rubbed by a dissimilar substance exhibits the property of attaching to itself light particles of matter, such as paper or cork. The substance which has acquired this property is said to be electrified. Says Professor McLewis in "Science Progress" (London): "Since the attraction can be made to vary in amount (by altering the extent of the rubbing or by the use of different materials), we infer that there must be such a thing as quantity of electricity. Very early experiments also demonstrated that two pieces of the same material, when rubbed with a second substance, exhibited towards one another a certain repulsive force. On the other hand, each piece vigorously attracted the substance with which it had been rubbed in the first instance. Such observations lead naturally to the idea that electricity is of two kinds, called positive and negative respectively, and, further, that two pieces of matter carrying electricity of the same sign repel one another, while oppositely-charged pieces attract. Electrical charges of various amounts can be given to a piece of material and can be removed from it by suitable means."

If we bring sufficiently close together two substances highly charged with electricity, the one carrying positive electricity, and the other negative electricity, a spark may be observed to pass from one to the other, after which we find the materials possess no charge whatsoever, provided, of course, the initial amounts of the positive and negative charges were the same. It is possible, therefore, to discharge the electricity from a substance by neutralization with electricity of the opposite sign. It follows that an uncharged or electrically neutral substance does not necessarily contain no electricity at all. It may really possess equal amounts of the positive and negative kinds.

These early observations and deductions, however, do not give us much information about the mechanism of the process of electrification. The charges of electricity considered above reside essentially on the surface of the materials examined. The first evidence that electricity could be transported through the body of a solid was obtained when an electrical current was propagated through a wire by joining the two ends of the wire to the poles of a battery. That an electric current or electricity in motion exists under these conditions is shown by its effect on a small magnet suspended close to the wire, the magnet being rotated through a certain angle when a given quantity of electricity passes through the wire. The modern view of an electric current is that it consists of a stream of very material particles called electrons or corpuscles, each of which, as we have before pointed out, carry an electric charge. The sign of this charge has been shown in various ways to be a negative one. These electrically-charged electrons existed in the wire all the time. Their movement from one end to the other was brought about by joining the wire to the battery, one pole of which acts like a reservoir-head applying a certain electrical pressure or potential which causes the electrons to stream just as water streams from high pressure to low.

Since the electrons are thus shown to be present in the wire, they must constitute part of the atoms of which the wire itself is composed. In virtue of the fact that it allows electricity to pass through it, a metallic wire is called a conductor, its conducting power being due to the pressure of electrified particles distributed through its mass. But wire is by itself an electrically neutral piece of matter. It follows, therefore, that there must be exactly as many positively-charged particles as there are negative. We now know as a matter of fact that in a piece of metal some of the atoms have lost each an electron, so that the atomic residues are positively charged, the charge being necessarily the same in amount as that carried by the detached electron.

To quote Professor McLewis further: "Certain aqueous solutions, notably solutions of acids, bases and salts, likewise allow electricity to pass through them. They are also called conductors, but the mechanism of the process is known to differ from that in metals. In the case of solutions the carriers of electricity are particles identical in mass with atoms, of which some are charged positively, some negatively. The solution as a whole is electrically neutral, there being just as many positively-charged atoms, or ions as they are called, as there are negatively-charged ions. These ions are present all the time in such solutions. Their presence is shown when we cause them to move by putting on an electrical pressure or potential through the intermediary of electrodes. It is then found that the positive ions move in one direction, the negative in the opposite. Each ion is attracted towards the electrode which has electricity opposite in sign to that carried by the ion. When an ion reaches an electrode it gives up the electricity to the electrode, the ion becoming thereby discharged. It is now simply a neutral atom. Several things may happen to this atom; e.g., it may be deposited on the electrode as in electroplating, or it may go off in the form of gas, as happens when we electrolyze a solution of common salt and obtain gaseous chlorine at one of the electrodes —each molecule of chlorine, by the way, consisting of two atoms of chlorine which have united with one another after being discharged at the electrode—or, finally, the discharged atom may react with the water, as happens in the case of the sodium atom, giving rise to new reactions such as the production of hydrogen gas and caustic soda, the latter in the dissolved state. The essential difference between the conduction of electricity in a metallic solid and that in a solution is the fact that no chemical or other change is produced in the metal, whilst marked chemical changes may be produced in the solution."

Recent investigation has shown, however, that we are unable to add or subtract any amount of electricity we please. There is a certain limiting amount below which we cannot go. This amount is identical with that carried by the single electron. Electricity or, more properly speaking, electrical charge is built up of certain natural units, each unit being identical in magnitude with the charge on an electron. In other words, electricity must have a discrete structure, just as matter has.

Electrons constitute the cathode rays, a stream of very fine particles produced when an electrical discharge is passed through a gas at low pressure. The stream of electrons is made manifest by a glow in the Crookes tube, in which this phenomenon can be produced. The glow itself is due to the collisions of electrons with gas molecules, the latter suffering ionization. The stream can be deflected by a magnetic field, which shows that the particles composing it are electrically charged, and the direction of the deviation so produced indicates that on the usual convention of positive and negative electricity the electrons are negatively charged. In addition to the cathode rays, in which the electrons are produced from the matter composing the electrodes, we likewise meet with their production from radioactive elements, from the alkali and alkaline earth metals, and in general from any material which is excited in a suitable manner, that is by exposure of the material to short wave or ultra-violet light. It seems natural, therefore, to regard the electron with its discoverer, Sir J. J. Thompson, as one of the bricks of which atoms are built up.

The existence of the natural unit of negative electricity being demonstrated, the question arises: is there a similar unit of positive electricity? Professor McLewis says: "So far, the answer is in the negative. We have not yet encountered a natural unit of positive electricity which is indivisible and capable of independent existence as in the case of the electron. At the present time positive electricity really denotes absence of a certain amount of negative electricity, i.e., absence of a certain number of electrons. Thus, it is possible to remove an electron from an atom of sodium, leaving us with a positively charged atom-residue or ion. The quantity of positive electricity on the ion is necessarily equal in amount, though opposite in sign to that of the electron itself.

"The charge on the electron is the smallest quantity of electricity capable of independent existence. Similarly the electron itself is the smallest portion of matter capable of independent existence.

The primary quality of matter is mass, and an electron is the smallest mass of material conceivable. No smaller mass has ever evidenced itself, though it has been carefully sought for. It is known that the mass of an electron is one eighteen-hundredth part of a single atom of hydrogen, that is, the mass of an electron is 5 x 10.28 gram.

"This quantity is so very small that its removal from an atom (of hydrogen, say) leaves us with a positively-charged residue, the hydrogen ion, which possesses a mass practically identical with that of the neutral hydrogen atom itself.

"The remarkable conclusion at which we have arrived, is then this: the smallest particle of matter capable of existence is known to us only in the electrified state—an unelectrified electron is physically inconceivable—and the amount of electricity which it carries at the same time is the smallest quantity capable of existence. This 'coincidence' of matter and of electricity is exceedingly significant. In fact, Sir J. J. Thompson has shown that the whole mass of the electron is electromagnetic, that is, in the electron, matter and electricity have become one. It is impossible to define the one except in terms of the other."

Atom Worlds

The conclusion reached above may seem startling, but so are all comprehensive conclusions startling when first we come in contact with them, yet the evidence scarcely permits our doubting the correctness of the conclusions that have been reached.

Professor Tait once said that all matter is in a sense alive, "Life sleeps in the mineral, dreams in the vegetable, and wakes in man." The latest conclusions of science in this regard seem to force us to the conclusion that there is no such thing as dead matter, that instead, the keynote of the whole universe is life. Science has taught us that the world just about us is quite as wonderful and as puzzling as that great army of worlds that glitter eternally over our heads, ever commanding our admiration at night. Even the delicate, star-shaped snowflake that rests for a moment on our sleeve in its white purity before it melts, is just as much a riddle to us as the stars of the universe. It is the colossal scale of construction of the heavenly bodies that renders those flaming worlds so imposing to our sight.

We know that even the smallest formation on earth consists of innumerable millions of those minute bodies we have been discussing, and which we call atoms or electrons; we know also that these minute bodies are in incessant motion even in the stones that lie apparently motionless at our feet. Natural science and chemistry have shown us that in every body, be it ever so tiny and composed of what it may, there are so-called atom-suns and atom-planets of almost incredible minuteness which constitute the whole. If we look at a pebble, or even a grain of common salt with this fact in our mind, and fancy ourselves the size of a germ, or even thousands of times smaller, and then imagine ourselves existing on an atom-planet in our pebble, it is quite possible that we should perceive the millions of atoms, divided from each other by relatively considerable distances, in the guise of a sea of stars similar to the one in the heavens of man. The whole of the atoms forming the stone would represent a Milky Way system to the stone inhabitant; and great men have frequently expressed the idea that the inhabitants of an atom might take their atom-universe to be the only existing world, just as we believe the mass of suns and solar systems above to be the universe, beyond which there is but an inconceivable void.

Verily an odd, a bizarre idea? And yet, where is there a final measure for nature's great handiwork—what is really "great," and what "really small"? It is just as easy to imagine a world on a scale as vast as the atom-world is tiny, to whose inhabitants our Milky Way system, with its millions of suns would be naught but a small body, and its suns but atoms. Singular thoughts you say. and hardly supported by the evidence that science brings before us. Yes, that is so, and to indulge in such dreams is almost to sink into bottomless space, into a shadowy realm of misty fantasy, where all our philosophy, work and strife, our whole being, energy and desires fade into ashen grey immeasurabilities. The stern realities of this our life dissolve the grey mists of our speculations into nothingness and the strange dreams that sometimes oppress our senses accompanies them.

The world whose existence we sometimes almost argue away ever lies before us in all its pristine freshness, and it is the one foundation of our toil, our development, and our being.

ENGINEERS LIFE NOT A BED OF ROSES

Continued from page 345

About a week after this, No. 1 boiler (the old No. 1) was cut out, No. 2 having been out of commission for some time, and the two boilers pulled down. The electric service was carried on outside power, the engine from the 25 kw. set had been removed and placed on a new base to drive the CO_2 compressor. The exhaust from this engine heats the domestic hot water and also any heating during the summer months (heating during the summer months may sound somewhat extravagant, but in reality it is very necessary, as many of the patients are babies). Tearing the boilers down took about two weeks. One set of tubes was stacked in the boiler room and the drum laid on top, the other drum was hoisted up to the ceiling and hung on straps and the tubes were hoisted out of the boiler room and laid out on the street. The foundations were at once dug and the concrete run in, during which time the pumps were moved round and placed in their new positions. The feed water line is in duplicate. There had been trouble with corrosion in the feed water pipe in the old layout, so it was decided to make the new line of brass. From the feed pumps to the feed water filter the pipe is iron, but from the filter to the end it is all brass, with the exception of the Venturi meter tube. After leaving the Venturi tube the line branches to two 2 in. pipes. All the fittings are extra heavy, and the nipples are extra heavy cast brass. The threads, both male and female, were cleaned with gasoline, and turned and screwed together whilst hot, after which the joints were wiped on the outside. The result is an absolutely tight main, a thing which is very difficult to obtain with brass pipe and fittings. The two lines are valved at two or three points in their length, and are connected together with unions, so that it is possible to take either line down and still feed all three boilers. The extreme ends are valved and unions are left so as to allow for washing the boilers or filling without metering the water. One feed pump was already in service on No. 1 boiler.

As soon as the concrete was hard enough to work on, the two boilers were reassembled and bricked in. However, having room and brick enough, these boilers were given 22½ in. side walls and 18 in. back walls. This allowed the Nonpareil brick to be placed inside the red brick. The bond between the red brick and the Nonpareil brick was a header course of Nonpareil brick.

When this was done the steam services were shut off one Saturday night and the stub end of the old breeching torn down and rebuilt to the size of the new breeching. This ended the brickwork in the boiler room. The floor of the boiler room in front of the boilers was immediately laid, the concrete mixture being 1, 2, 3, with Master Builder's finish. The floor is sloped from one end and drains into the sump, having aa gutter close to the wall all round the boiler room.

As already mentioned, the middle steam nozzle on No. 1 boiler was blanked with one of the old 5 in. gate valves, so the expansion bend of 4 in. extra heavy Byer's pipe was put on and the installation of the steam main proceeded with. As was shown in the original plans, the engine main was 8 in., and the intention had been to connect this 8 in. pipe to the new main with a 6 in. connection. However, during the period of construction the 8 in. main began leaking in two or three places at the pipe threads, so it was decided to replace it with a 4 in. line. So a 4 in. line is now in place of the 8 in., and is carrying all the engine load.

As soon as the double battery was built the feed pipe was run across to No. 3 boiler and the main header was proceeded with. The connections for No. 3 boiler were blanked off with valves so as to reduce the time needed to get one boiler into service. As soon as No. 3 was under steam the steam connections to No. 2 were gone on with and then the auxiliary main was finished. Last of all the high pressure permanent mains were put in and connected. It was found advisable to provide a duplicate steam line for the main operating room service. This is made up of two 2 in. lines about 150 ft. long, and takes care of operating

room, kitchens, dish sterilizers in the wards, and also supplies steam to a 12 x 8 x 15 Duplex house and fire service pump. There is a reducing valve at the end of the line for kitchen service.

The safety valves were connected as shown in the new plans, using swing joints to take up the expansion to the outboard exhaust pipe so that there is very little noise either inside the plant or out, when the valves blow.

The bottom blow-offs were connected to the blow-off tank separately, using Byer's extra heavy pipe and extra heavy long turn fittings. The valves are a 2 in. bronze gate valve, supplied with the boilers, and a 2 in. Jenkins Y valve. All the other brass valves are Penberthy Company's, the iron body valves are Jenkins Bros. The blow-off tank is buried in the floor. It was painted with three coats of bituminous paint and placed on end on a concrete base and filled around with six inches of concrete, reinforced with ⅝ irons. The manhole of the tank is above ground. Each blow-off pipe has a suction tee on the end, which acts as a muffler. The discharge from the tank is a 3 in. pipe laid in a floor trench which acts both as pipe trench and floor drain. The boilers can be blown down thoroughly now without the men getting nerves over the job

The pipe covering was applied by the Armstrong Cork & Insulation Co., who, by the way, were the only contractors besides the building contractors. The tops of the boilers were covered with 1 in. high-pressure cement, then Nonpareil insulating brick on edge, 4½ in. thick, and a final coat of Portland cement. This has proved entirely satisfactory, the top of the covering feeling only warm to the hand.

As mentioned previously, a 2 in. Venturi meter was installed on the feed line, the recorder being in the chief engineer's office. There are also connected to the breeching of each boiler a thermocouple of a Thwing electric pyrometer, and a suction pipe for a Hay's flue gas analysis set. These are also in the engineer's office, so that it is possible for the engineer to get the feed water, the flue gas temperature and the CO_2 reading without going down to the boilers.

The stokers are driven by individual motors. These are 1 h.p. Roth, 220 v. d.c. motors, back-geared, using a rawhide pinion on to a cut steel gear. Roller chains are used to drive the stoker countershafts from the motor jack shafts. The countershafts are all in line and fitted with Clark couplings so as to allow them all tobe driven from one motor or engine if found necessary. S. K. F. ball-bearings are used on the stoker countershafts and on the ash conveyor and wherever dirty or dusty conditions prevail, and up to the present, which is now about two years from time of installation, have proved quite satisfactory.

This concludes the description of the remodelling of this plant. Any other points of interest which may develop will be made the basis of future articles.

AN AUTOMATIC ENCLOSED GASOLINE ENGINE

By FRANK C. PERKINS

The automatic four cylinder enclosed gasoline engine noted in the accompanying illustration was developed at Bridgeport, Connecticut, U.S.A. This four cycle marine motor is said to have maximum economy of fuel and upkeep. It has a bed consisting of a substantial one-piece iron casting, the lower half being octagonal in shape, cast integral with base and with large oil reservoir located in center. There are flanges on either side for bolting to the frame work, and a square groove through center of base for crank shaft bearings. The sub-base is fully enclosed and securely bolted to the bed, on top of which are mounted the cylinders, magneto and governor assembly. In the side of the sub-base are hand holes for ready access to make adjustments on connecting rod and crank shaft bearings, while the cam shaft is also located in sub-base.

The square groove in the bed receives the crank shaft bearings and upper half of the gearing is reinforced by a steel plate onto which the cap adjusting screw rests. The bearing adjustment is made by turning an extra large octagonal head screw with keeper. This method permits adjustment without loosening the cap, which is thoroughly and permanently fastened in position. The keeper prevents this screw from working in either direction, and makes a quick and efficient adjustment.

The balance wheel is made with a split hub, bolted to crank shaft with four large bolts; also fastened with a large square key, insuring a perfect fit with no side motion or wobbling. Because of this split hub the balance wheel is easily taken off when necessary to do so. The crank shafts are hammered from solid blanks of high-carbon steel and one cam shaft only is used, of 40 carbon machinery steel and on the shaft are cams for operating inlet and exhaust valves. The solid bearings for this shaft are of cast iron with bronze bushing.

The cylinders are of L type, one-piece castings, having separate heads. The top face of cylinder is without cored holes, except one for circulating water, and this is outside, so that there is no possibility of water entering the cylinder. The cylinder heads are cast of the same iron as cylinders, with ample water space around valve hole covers. In coring the cylinder heads there is no opening whatever between the head and cylinder, except at the extension for water provided to meet extension in cylinder. The water circulation is of special interest. Extra large water space has been allowed in the cylinders, cylinder heads and around valve seats, the water being supplied by a plunger type of pump attached to the aft end of each engine and operated by an eccentric on the cam shaft.

The valves are of nickel steel, the end of the stem being threaded and provided with special clasping locknut for adjustment. The valves are so situated that they may be reground and seated without removing cylinder head. The valve head caps are of cast iron with air-cooled vanes to assist cooling spark plugs. The valve lifters are of the mushroom-head type, slightly off center of cams, and made of open-hearth steel, fitted into separate cast bushings and held securely to the sub-base. This type of lifter allows a great area of opening for a long time, which is most desirable.

The lubrication is provided by a large geared force pump, connected to the spacious reservoir in bed of motor. The question of oiling an engine thoroughly has been taken care of. The oil pump is located inside forward end of engine.

Simple Methods of Determining Power Costs

Ability to Show Engine Room Performance by the Medium of Dollars and Cents Useful to the Engineer—How to Arrive at Costs When No Instruments Available—Easy Methods

By T. H. FENNER, Associate Editor

IT is by no means an unusual thing to hear a power plant engineer say, "It's no use trying to improve this plant. The manager won't spend a cent." In some cases this may be true, but in many more cases the reason is that the arguments put forward by the engineer fail to convince the manager or owner of the benefits to be derived from the outlay. This does not perhaps apply to the larger plants but to the average run of industrial power plants. The large power plant is usually well equipped to begin with, and costs are fairly accurately known. In the smaller plant very often the only costs that are known are the actual wages, coal, and stores as items of expense, without any definite knowledge of the proportion of power costs to manufacturing costs. This works to the disadvantage of the engineer, both as regards his chances of increased salary and his credit as a successful operator. It is therefore to the benefit of every engineer to study the elements of cost accounting so as to arrive at an understanding of his plant considered as a business proposition. That, after all, is what any power plant really is, whether it is a 50,000 h.p. central station or a 200 h.p. factory plant. The central station is manufacturing power to the public, and the factory power plant is manufacturing and selling power to the factory. The engineer should so endeavor to run his plant as to show a profit at the end of the year, and to do this he should know the actual cost of running each unit, main and auxiliary in his power house. If the office staff carries a cost accountant, the engineer, by getting in touch with him, can learn much that is of value to him, and incidentally can help the cost accountant to some extent in return. Where such a person is not employed it is up to the engineer to figure things out for himself. This does not mean that he should become an expert in costing, for that requires years of training, but a little study will well repay him by putting him in a position to be able to talk intelligently when the subject of new equipment and alterations come up. A little enquiry into the way that costs are figured will sometimes reveal things which are distinctly unfair to the power house. For instance, it is the practice of some companies to compare the weekly coal consumption against finished production. This may be a handy method of general results from the executive's standpoint, but it is grossly unfair to the engineer. For instance, we will take two consecutive weeks. The first week, the plant burns 20 tons of coal, and the factory produces 1,000 finished articles. The following week the plant burns 20 tons of coal and the factory produces 800 articles. Now this drop in production may be the result of any number of causes in which the power house does not figure, and the same amount of power may have been expended in producing the 800 articles as there was to produce the 1,000. For instance, there may have been 1,000 articles finished as far as any operations needing machine work are concerned, but still requiring some small additions, perhaps soldering, or transfer ornamenting, or final inspection. The same amount of power has been used but without producing the result. Now this comparison is probably brought to the engineer, who in many cases knows nothing about factory conditions, and he is informed that production costs are going up, and he is burning more coal than he should for the results obtained. He can't understand it, but in the face of the manager's figures,

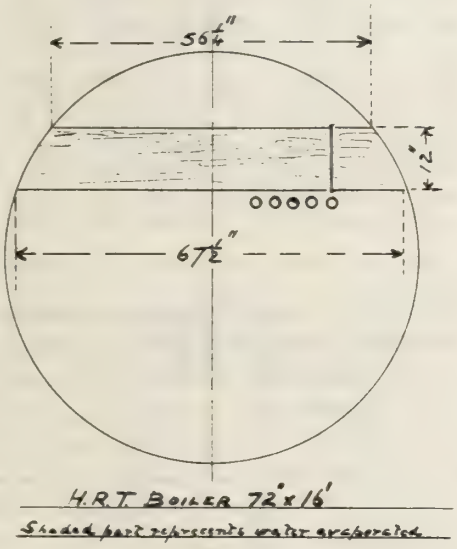

FIG. 1

against which he has none of his own, he is helpless. He feels that he is suffering from an injustice, but can not lay his finger on it. In another case, due to change of labor, breaking in new hands, inspector's carelessness, etc., a great deal more scrap may be made one week than another. In this case more power is used for less production. The engineer should always have figures to shew that his coal costs bear a definite relation to the power generated, and then production is a matter for the factor, and not for him. The means of obtaining these figures will vary according to the plant, as to its size and the provision or lack of suitable recording instruments. Let us take the simplest case, that of the plant containing one boiler, and an engine, driving a shaft through a belt, or direct connected to a dynamo. The auxiliaries in this plant will be limited to the boiler feed pump, and perhaps a vacuum pump connected to the heating system. The instruments available will be likely confined to a recording steam pressure gauge, and perhaps not even that. Here, it will be said, there is not much chance of getting particulars. However, they can be got. If the engine is driving a generator, which supplies current for power and light, the amount of power generated can be read off the switchboard instruments direct. Readings taken hourly or half hourly over a period of say two weeks will establish a very fair average of total load. By running the engine for half an hour at night with power off and all lights on, the total lighting load can be found, and the proportion of lighting load to power load determined. The next step will be to find the average consumption of coal per k.w. hour. To do this it will be necessary to run the boiler on the engine only. The methods to be pursued to do this will depend on the arrangement of the plant, but generally speaking a plant such as we are discussing will have one main stop valve on the boiler, and a branch leading to the heating system, and any steam used for process work is taken off this line. It is generally possible, by a little tact, to arrange with the several foremen or factory superintendent, to shut the steam off the factory for an hour or two, during the day, and if this can be done, the task is easy. Have the floor in front of boiler cleaned up, and the fire in good condition, when the time arranged for shutting off the auxiliary steam arrives. Then have two or three barrows of coal ready weighed, and start on them right away. Note the time, and keep the water level in the glass. When the time is up, weigh any coal that is left over, and deduct from the total used. Read the switchboard instruments carefully while the test is on. You then have a definite amount of coal for a definite amount of power, and the consumption per k.w.h. is readily arrived at. This figure includes the feed pump consumption, but as the feed pump must run whenever the boiler pump runs, this is quite legitimate. There is now to be considered the consumption on process work and heating. The best method for determining the consumption on drying ovens, etc., is to weigh the returns, and the method of doing this lies mostly with the individual engineer's ingenuity. A consumption meter devised by the writer is described in last month's POWER HOUSE. A tank placed on a scale and watched by a boy might serve, or the number of times a trap discharges in a given time could be recorded. The heating system pretty well takes care of itself in this way; that during the day time the engine exhaust is usually supplying the steam for heating, and any extra consumption at night or over week

ends observed in winter as against summer, can be put down to heating. However, if necessary, the heating consumption can be pretty accurataely figured. The total heating surface in square feet can be measured up, and then if 1.5 B.T.U. per sq. ft. surface per degree difference of temperature is allowed, the total quantity of B.T.U. required is given. Take steam at 2 lbs. gauge, and divide the total heat of one lb. of steam into the total heat required, and you have a fair estimate. This does not account for different exposure, but if it is figured on a 60° difference, it comes pretty close. It can be checked up by actual experiment. Take some Saturday afternoon or Sunday when no work is being done, and the heating system is running. Simply weigh the coal for an hour or two, and you have the coal consumption. None of these experiments have given us the evaporation per lb. coal. This can be obtained by direct observation, in a simple way. Fill the boiler till water is up to the top nut of the glass, and stop the pump, noting the time carefully. Wait till the water is at bottom nut, and note time again. Fill up and repeat several times, the more the better. Weigh the coal carefully during this time, and you have lbs. water evaporated per lb. coal actually.

Boiler 72" dia. x 16' long.
Length of glass between nuts, 12".
Width of top surfaace, 56¼".
Width of bottom surface, 67½".
Mean width =

$$\frac{\text{Top} + 4 \text{ times middle width} + \text{bottom}}{6}$$

$$= \frac{65.25 + 4 \times 63 + 67.5}{6} = 62.625 \text{ in.}$$

$$\text{Volume} = \frac{62.625 \times 12 \times 192}{1728} = 83.5 \text{ c.f.}$$

$$\text{Weight} = \frac{\text{Cub. Ft.} \times 62\ 5}{} = 83.5 \times 62.5$$

In this way the consumption of the engine can also be determined if there are no switchboard instruments to read. This does not give horsepower, but consumption steam per hour. If the plant has an indicator, then engine horsepower can be obtained, but we are taking the case of a plant with no instruments for measuring or with merely the switchboard instruments. Supposing our engineer to have been sufficiently interested in his job to make these simple tests, he can now go ahead and tabulate the results in a form that will be easily kept written up, and compared one week with another. We have determined the lbs. of coal required to produce 1 k.w.h. and also the coal required for all process work, and heating. We have also determined the evaporation per lb. coal. It is not pretended that these results are minutely correct, but they are quite close enough for the purposes required. A form drawn up as follows will enable the engineer to show exactly what he is doing, and also to see if any quantity increases suddenly from its normal. On the form should be shown the hours run per day and per week, average volts and amperes per day and week, kilowatts, and kilowatt hours. The coal consumption having been determined, the total k.w.h. generated × lbs. coal per k.w.h. gives consumption for power. The proportion of lighting load can be separated if necessary from this. As a matter of fact, where hourly or half hourly readings of the switchboard are taken, the increase due to lighting load can be plainly seen. Another column shows number of hours steam is being supplied to drying ovens, and as we have determined the steam consumption per hour, and also lbs. steam per lb. coal, the steam consumption divided by lbs. steam per lb. coal multiplied by number of hours gives consumption for this purpose. This would be

$$\frac{\text{hrs. run} \times \text{stm. cons. per hour}}{\text{lbs. steam per lb. coal.}}$$

Take another column for repairs carried out in the usual run of operation, and cost of same as nearly as can be ascertained. Keep a record of oil used per week in another column, with its cost. Summarize all these as shown, and you have detailed information regarding the operation of your plant. If any one item shows an unusual quantity you can investigate it, and find the cause. If there is a discrepancy between the amount of coal actually burned, and the amount accounted for by your form, look into it. The two quantities should check up nearly equal. In making up the cost per k.w.h. the first cost is determined by simply taking the lbs. coal burnt per k.w.h. as determined by test. Say that 4 lbs. coal is burnt per k.w.h. was the quantity determined. There are 2592 k.w.h. generated, 2592 × 4 = 10368 lbs. coal. Coal

Steam generated = 137192 lbs.
Cost per 1000 lbs = 31.3 cts. fuel only.
Cost per KW Hr = 1 cent "
" " " " = coal & maintenance (wages - Repairs - depreciation etc)

Engine Room Report. Week ending March 25/18

James Smith Chief Engineer

FIG. 2

at $5 per ton is ¼ cent per lb. $10368 \times .25 = 2592$ cents.

$\frac{2592}{2592} = 1$ cent per k.w.h. Cost of steam per 1000 lbs. is taken by multiplying the total coal burnt by the evaporation figure obtained. Say this is 8 lbs. steam per lb. coal. Total coal burnt is 17149 lbs.

$17149 \times 8 = 137192$ lbs. steam.

$4287 \div 137.192 =$ cost per 1000 lbs.

or $\frac{1000}{8} \div$ lbs. coal per 1000 lbs. steam.

$\frac{125 \times 500}{2000} =$ cost per 1000 lbs.

In making up the cost per k.w. hour, including maintenance charges, etc., we must figure proportion of wages, etc., to be charged to power only, also depreciation of buildings, repairs, etc. In the kind of plant we are thinking of the engineer will probably do all his repairs himself. He will have a fireman all day, and the night work will usually be attended by the the watchman. As there will be no power at night this does not come in. We have a total amount of coal burnt, 17149 lbs. The proportion of this coal for power only is $\frac{10368 \times 100}{17149} = 60.4\%$.

We will say the engineer's wages are $25 per week, and the fireman $18, that is $43. The proportion of this amount to be charged to power will be $\frac{43 \times 60}{100} =$ $25.80. Repairs amount to $15. Oil to $3.85. The depreciation charges must be obtained from the office, in fact this item could be made up entirely by the office staff. However, taking the costs we have, we get—

Coal	$25.92
Wages	25.80
Repairs	15.00
Oil, etc.	3.85
	$70.57

$\frac{70.57}{2592} = 2.72$ cents per k.w.h.

The cost should be, generally, much less than this, but will, of course, depend on the efficiency of the boiler and engine. In the case of the engine driving the factory through a belt, the cost per horsepower would have to be taken, instead of that per k.w.h. The consumption per horsepower can be arrived at by use of the indicator, or if there is none, by using the measurement of water evaporated as already explained. With these quantities on file week by week, the engineer is able to meet the manager on ground which the manager is familiar with, and is able to shew if production costs are rising, whether the power plant is to blame or not. The initial determination may entail some work, but once obtained the figures are good unless some radical alteration in the fuel is made, or the equipment suffers deterioration. The figures themselves will show if efficiency is going up or down.

The Control of Large Amounts of Power

The Author, in a Paper Read Before the Institution of Electrical Engineers, England, Gave Some Interesting Information Regarding the Control of Large Amounts of Power and Use of Reactances

By E. B. WEDMORE

THE increasing use of electrical energy and its economical production require the use of larger generating stations and the linking together of existing plants. These extensions involve something more than the use of larger units and the adding of unit to unit. New conditions are reached. Factors which were negligible in smaller aggregations of plant become serious and limiting features.

The forces accompanying a disturbance are increased, and the total number of disturbances to which a system is subjected increases automatically with each extension; thus there are introduced new problems in the design of individual parts of the plant and in the arrangement of them.

There are no insurmountable difficulties in the design of larger machines, heavier cables, and of switchgear all able to cope with larger forces than have yet been met with, but a little consideration will show that the limiting features are to be looked for not only in the generating station, but in the distributing system. Stations and networks spread over a large area may be coupled together without necessarily seriously modifying the forces to be dealt with at any point, but a striking characteristic of developments now in prospect in the principal industrial areas is the increased concentration of large amounts of power in small areas. This inevitably follows the extended use of electricity for domestic purposes as well as for power production, and introduces new conditions not yet fully recognized.

One may double the size of a generating station with advantages in economy and without excessive expenditure on switchgear to take care of the conditions in the station itself; but for every machine, switch, and conductor in the main station there are large numbers of smaller machines, switches and conductors in the distribution system, and if these also are subjected to increased forces a very heavy expenditure may be necessary to ensure satisfactory service. Not only is this true as applied to an individual town, but similar conditions may arise where a large bulk-supply scheme is devised and a number of existing small plants are linked up to a common and larger source.

It is, therefore, very necessary to give full consideration to the new conditions introduced, and in this paper an attempt is made to anticipate the probable developments of the immediate future, and to show how the conditions arising may be dealt with.

The problem of maintaining continuity of supply and of protecting the plant is found to require for its solution the proper proportioning of the impedance of the different parts of the system.

There are also a number of practical details to be considered in the design and arrangement of the distribution apparatus and the feeder system.

The employment of current-limiting reactances has been already dealt with in a paper by Messrs. Faye-Hansen and Peck, but the subject has been treated afresh with the object of ascertaining the limiting features in the practical applications of reactance and presenting them in a form for immediate use.

Prospective Developments

Engineers have long since anticipated the possibilities of big developments in the use of electric power, and in its more economical production and distribution. The use of electricity in metallurgical and chemical processes is opening up a new field, but apart from new outlets there is scope all over the country for manifold extensions in the use of electricity for domestic and general industrial purposes.

In this report the design and use of alternating-current generators in units up to 50,000 h.p. and over has been discussed.

Stations have been laid down for an ultimate output exceeding 200,000 k.v.a., and this figure has been approached in installations already in operation.

In this paper the station with 100,000-k.v.a. output is taken as typical, but consideration is also given to the linking together of such stations, and of smaller sources of power such as waste-heat stations and existing generating stations of limited capacity.

As for the size of generating units, it will be seen in what follows that the general use of generator units of the order of 50,000-k.v.a., output would

throw excessive stresses on distribution apparatus and small plant generally unless special precautions are taken. There are, however, other considerations also which point to the use of smaller units.

In the first place the question of spare plant has to be considered. We have to consider that a large unit may fail at a time when another similar unit is temporarily out of commission, pointing to the provision of two spares of the largest size. This is increasingly important on large systems where more and more services become dependent upon the electric supply, and where the load factor is high. The time required to restore to service units of this magnitude that may have been put out of commission is much greater than in the case of units with which most of us are familiar.

This and the fact that such large units could not be employed economically except on large interconnected systems with a total output greatly exceeding 100,000 k.v.a., all supports the contention for the general use of machines of 20,000 to 30,000 k.v.a.

Means must be found to ensure maintenance of voltage at all parts of the system and to prevent the disturbance of running machinery.

Means must also be found to limit the power which can be concentrated at any point on a fault occurring, and to a figure not calling for excessive expenditure in the construction of individual pieces of apparatus.

That special steps are necessary will be abundantly clear when it is stated that if practice hitherto prevailing is followed in the extension of existing plants, switchgear on consumers' premises may be subjected to forces comparable with those now met with in large generating stations.

Let us assume a generating station of 100,000 k.v.a. output feeding a large town by stepping up to 20,000 volts and transmitting 20,000 k.v.a. to each of five centres at a distance of about 3 miles. The generators and step-up transformers may be taken to have 14 to 15% short-circuit reactance; thus there will be liberated 700,000 k.v.a. on a fault near the station. Allowing 4% reactance in the step-down transformers, and allowing for feeder impedance, there will be 200,000 to 350,000 k.v.a. liberated on a fault on the busbars at a distributing centre according to whether or not these centres are interconnected.

If now the pressure is stepped down to 6,000 volts for distribution through 0.1 sq. in. feeders a mile long, the additional impedance of individual feeders will not limit the energy liberated even at the remote end to below 100,000 to 150,000 k.v.a., and this figure may be doubled by feeders in parallel. Thus not only will all switches on consumers' premises within a mile radius have to meet these severe conditions, but all conductors or pieces of apparatus will be subjected to the corresponding mechanical forces and heating effects.

It must be remembered, too, that these figures of 100,000 to 150,000 k.v.a. represent values which will not be materially reduced before the switches open, even though delayed as much as a second, as the generating plant is much better able to maintain this output than it can the heavier short-circuit currents met with close to the source of supply (see Fig. 1).

If the plant was originally a small one supplying at 6,000 volts and were to be extended to the same capacity of 100,000 k.v.a. output, there would not be the limiting effect of the step-up transformers, and the maximum short-circuit near the source would be 1,000,000 k.v.a., and at the end of parallel 0.1 sq. in. feeders one mile from the distributing centres 400,000 k.v.a.

This figure is about 20 times what commercial switchgear on consumers' premises will withstand without support. It would raise the temperature of the feeder conductor at the rate of 2,000 degrees C. per second, and this fault in an individual consumer's premises would pull down the voltage throughout the whole system.

By suitably proportioning the impedance of the different parts of the system, and by the employment of quick-acting selective protective apparatus, we can, however, both limit and localize these disturbances.

Limitation by Sectionalizing and the Employment of Reactance

By the crude method of sectionalizing the plant we reduce the conditions to what they would be on small plants, and this has been done extensively. The object, however, of large combinations of generating plant is economy in production, and this is obtained by an interchange of energy between the different sections, which enables larger and more economical units to be employed, reduces the number of spare machines necessary, and improves the load factor. Thus it is interchange of power we have to provide for.

On a large plant we can to a considerable extent regain the easier conditions of small plants by dividing the system into sections and paralleling these through reactances. This will admit of the interchange of energy for purposes of economy, and at the same time limit both the interchange of energy during severe faults and the disturbance of sound sections.

The employment of reactances for interconnecting, whether between busbar sections in an individual station, in trunk mains between busbars in different stations, or in interconnectors between adjacent parts of the distributing system, has the distinctive merit that, so placed, they carry only that portion of the load being transferred from section to section, and thus waste a minimum of energy and do not interfere with regulation.

Reactance may also be employed in series in any part of the system, but, so used, the reactance will have to carry the total load fed to that part.

Wherever employed the reactance limits the disturbance in all parts of the system beyond it and tends to isolate the disturbance from all parts nearer to the source of supply.

The desired results will be most economically obtained when interconnecting reactances are employed, but if the inherent reactance of the circuits, transformers, etc., is insufficient adequately to localize the disturbance, the employment of a certain amount of artificial reactance in series will be necessary also.

The different methods of employing reactance with their advantages and disadvantages are set forth in the schedule given herewith.

The conclusions in the schedule are now to be explained and illustrated.

In discussing the use of reactance it is found convenient to rate the reactance in terms of the percentage reactive voltage-drop it will give on the full-load rating of the part of the plant with which it is associated. Just as we speak, for example, of a transformer having a reactance of 4 per cent., so we speak of a busbar section reactance of 10 per cent. based on the current rating of the section. This rating of reactances is considered further along.

Limitation by Generator Reactance

Reactance may be employed at the source, viz., in or with the generators themselves, where it need not interfere with the losses. It is anticipated that this method will be carried further than it has been hitherto.

It is quite feasible to build machines economically with much larger internal reactance than has been common practice hitherto. The inherent regulation will not be so good, but the normal load fluctuations on large plants with large machines are relatively slow, so that no difficulty arises in practice.

Some of the reactance may be external to the machine. Whether the reactance be internal or external the busbar voltage is maintained by hand or automatic control of the field.

An external reactance serves to limit the short-circuit current which can flow into a faulty machine, but this provision should not be necessary. After provision has been made on a large system for the proper protection of supply and of the plant generally, it will be found that the generator will not be subjected to excessive forces. From this standpoint it is better to put the reactance into the machine.

Most generating sets will be used in conjunction with step-up transformers, the machine and transformer forming one unit. In this case the transformer reactance will be additional to that in the machine and will add, say, 4 per cent., but there is no reason why the transformer should not be designed to give more than this, and at a lower cost than that of employing a separate external reactance.

There is a practical limit to the extent to which satisfaction can be obtained by the use of generator reactance, and that arises from the fact that reactance in this position serves only to reduce the magnitude of the short-circuit currents and does nothing towards maintaining the supply voltage in the rest of the system in the event of loss of voltage by a fault at a point. In order to maintain the supply voltage, we must employ a proper ratio of busbar reactance to generator reactance and of feeder reactance to generator reactance; and as it will be found that the amount of busbar or feeder reactance which can be used is limited on account of interference

SCHEDULE.

CONTROL OF LARGE AMOUNTS OF POWER BY USE OF REACTANCE

Requirements.

To limit the area affected by a disturbance at any point.

To limit the power concentrated at any point on a fault occurring.

Characteristic.

Wherever employed, reactance limits disturbance in all parts of the system beyond it, and tends to isolate disturbance from all parts nearer to the source of supply.

Means.

A—*Utilization of inherent reactance.*—Advantages: Saves cost of special reactances and does not add to resistance and consequent losses.
Limitations: Where the load is at all concentrated. cannot be carried far enough for economical reasons.

B—*Utilization of artificial reactance.*—Advantages: Can be located where most effective.
Limitations: Must not interfere with regulation.

Method of Employing Reactance in General.

I—*Reactance in series.*—Advantages: Easy to apply.
Limitations: Carries total load fed to part protected.

II—*Reactance in parallel.*—Advantages: Carries only portion of load transferred. Wastes less energy.
(Sectionalizing or interconnecting) Interferes less with voltage regulation.
Limitations: Requires sectionalizing of distributing system. Is not sufficient alone if good regulation maintained.

Methods of Employing Reactance in Series.

(*a*) *In generator.*—Advantages: Cheaper. Does not hinder voltage control under normal conditions.
Limitations: Considerations of design of machine. Must not swamp isolating effect of busbar and feeder reactances.

(*b*) *Added to generator.*—Advantages: Limits current which can flow into faulty machine.
Limitations: Increased cost and space required. Must not swamp isolating effect of busbar and feeder reactances.

(*c*) *In feeder.*—Advantages: Gives best protection to rest of system.
Limitations: Interferes most with voltage on part protected.

(*d*) *In group of feeders.*—Advantages: Minimum number of reactances required. Protects feeder switchgear.
Limitations: Involves several feeders where fault in one.

with regulation, it follows that the generator reactance is also limited if a proper ratio is to be maintained between the two.

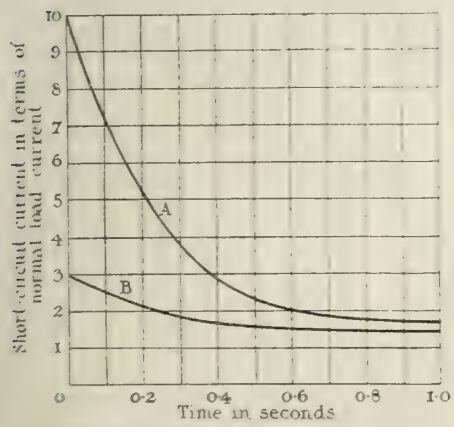
We are concerned with the magnitude of the rush of current which follows the development of a fault. The heavy current demagnetizes the field and reduces the current values, as indicated in Fig. 1, but at the first instance the field is sustained by eddy currents set up in the magnetic circuit, and the current is limited solely by the reactance of the windings.

Limitation by Feeder Reactance

The employment of artificial reactance in series with the load leads in any case to waste of energy and impaired regulation, and is, therefore, to be sanctioned only where no better solution is available.

Resistance and reactance in an individual feeder anywhere in the system affect disturbances in the following manner:—

(1) The feeder impedance helps to



A=Dead short-circuit
B=Short-circuit limited by reactance in circuit

FIG. 1—SHOWING DECREMENT OF SHORT CIRCUIT CURRENTS IN TYPICAL GENERATOR.

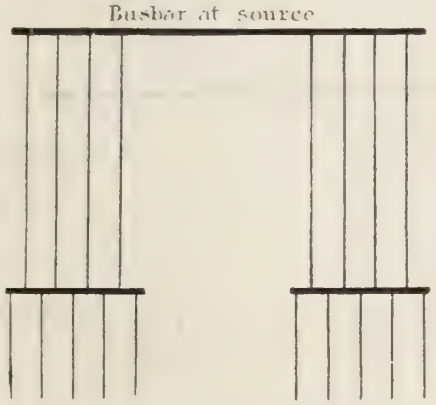


FIG. 2—ARRANGEMENT OF FEEDERS. GIVING LOW INHERENT IMPEDANCE.

maintain the voltage on all parts of the system connected on the source side of the impedance.

(2) The feeder impedance assists in limiting the magnitude of the fault current at any point beyond the impedance.

(3) The voltage at all points beyond the impedance is equally disturbed.

If artificial reactance is to be employed, functions (1) and (3) call for the reactance to be located as near as possible to the point to be protected, whilst function (2) calls for the reactance to be located as near as possible to the source of supply.

Inherent reactance may be utilized, however, in such a way as to serve all three functions, as may be seen by comparing Figs. 2 and 3. Fig. 2 shows power fed through eight feeders to two substations and distributed through 10 outgoing feeders. In Fig. 3 the same eight feeders are divided into four groups of two and there are 16 outgoing cables of smaller section.

It is clear that in the latter diagram we have not only increased the number of sections and thereby reduced the area affected by a given fault, but we have doubled the impedance between each substation and the main station, and greatly increased also the impedance in the outgoing feeders.

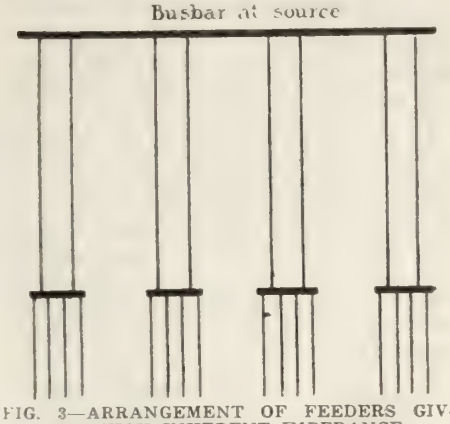

FIG. 3—ARRANGEMENT OF FEEDERS GIVING HIGH INHERENT IMPEDANCE.

From the practical standpoint, Fig. 4 may require more cables by way of spares and a larger staff of attendants, but there is an offset in that the substations may be placed nearer to the demand and the average length of the feeder reduced. Moreover, cable can be reduced by interconnecting stations if appropriate protective apparatus is employed, so that in fact subdivision can be pushed a long way without increased cost of distribution, and with great advantage from the standpoint of continuity of service.

Thus by separation of feeders we can introduce more impedance both near the source and near the parts to be protected.

At the same time if the total section of copper remains the same (neglecting the slight impairment of load factor) the losses are not increased and the regulation is unaffected.

In large systems where step-up and step-down transformers are employed, these introduce further inherent reactance, so that in practice, except where there is considerable concentration of load, the use of artificial feeder reactance should be avoidable.

Where artificial reactance is required, it should be put as near as possible to the point to be protected. Thus in Fig. 4 reactance should be inserted at "X" only if it is necessary to protect the substation plant. For the protection of consumers' apparatus position "Y" is the best, as this gives better voltage regulation.

Fig. 4 represents a distributing system with series reactance inserted at the source end and at distributing centres, in successively smaller branches of the system. We have to consider the relative merits of the two positions. The reactances at X and Y respectively carry each one-quarter and one-sixteenth of the total output. If we require to protect the individual feeders and their equipment, should we select the position X or Y? For equal protection we shall require equal ohmic value in the reactance in either position, so that the k.v.a. ratings will be proportional to the square of the current capacity. The cost of the reactances will be very roughly proportional to the square root of the k.v.a. rating, so the total cost of the reactance equipment will be of the same order for either position.

The effect on the working conditions, however, will be very different, for reactance at X will give four times the drop and waste about four times the energy of reactance at Y.

The use of series reactance interferes with the regulation to an extent which

may be quite serious for lighting unless the energy is transformed to continuous current. The permissible pressure drop ultimately decides the practicability of the proposition.

If the power factor of the load is 80 per cent., then the magnetizing component is 60 per cent. and a 10 per cent. reactance will cause a 6 per cent. drop, and for other sizes pro rata.

In the case cited where the inherent reactance limits the kilovolt-amperes on short-circuit to 100,000 to 150,000 k.v.a., for example, this figure can be reduced to 20,000 k.v.a., or well within reasonable limits for consumers' premises, by the employment of series feeder reactance introducing potential drops as follows on a load circuit of 80 per cent. power factor:—

Load.	Potential drop.
1,000 k.v.a.	2½ per cent.
2,000 k.v.a.	5 per cent.
5,000 k.v.a.	12½ per cent.

In this case the potential drop could be reduced only by improving the power factor, or by the use of less reactance and switches of larger rupturing capacity.

We shall see, however, that much better conditions can be obtained by a proper use of reactance at the generating station, in the machines, busbars, or feeders as required, to reduce the short-circuit currents at the substations.

In new large power stations it is wise to provide space for the possible addition of feeder reactance.

We conclude that inherent reactance should be utilized as far as possible, and additional artificial reactance should be used only to ensure that disturbances should be sufficiently localized and plant adequately protected against excessive stresses.

These two conditions require a similar distribution of reactance in the system, but the results obtainable from the standpoint of voltage disturbance depend upon the kind of plant employed.

Limitation of voltage disturbance:—We may consider three typical cases, viz.—

(a) Distribution for lighting, through transformers.
(b) Distribution through induction-motor-driven sets.
(c) Distribution through rotary converters and synchronous motors.

(a) Where the distribution is by transformer the voltage must necessarily be disturbed to an extent visibly affecting the lighting on sections adjacent to the faulty one, but the disturbance will last only until the protective gear has isolated the fault.

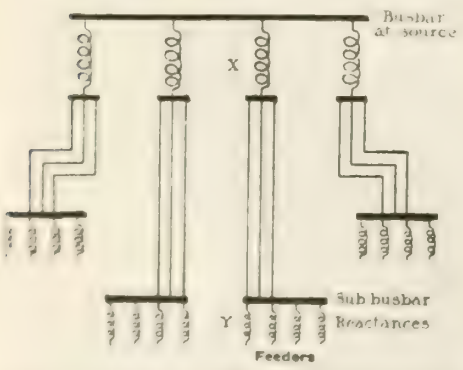

FIG. 4 LOCATION OF FEEDER REACTANCES.

(b) In the case of induction motors a heavy fall of voltage is not serious so long as the fault is cleared in about 2 seconds or less, which lies well within the capacity of modern protective apparatus.

(c) In the case of rotary converters and synchronous motors, we have only approximate data, but can form a good general idea of what is required. A rotary converter running fully loaded will not be pulled up if the voltage falls to one-third or one-quarter of normal, but the machine is sensitive to sudden changes of phase angle. The reactance which limits the voltage drop also reduces the phase-swinging. Faults remote from the source present no difficulty, but we cannot employ sufficient reactance in outgoing feeders in the generating station to prevent the voltage being pulled down on a fault. It is likely, however, that the machines on sound

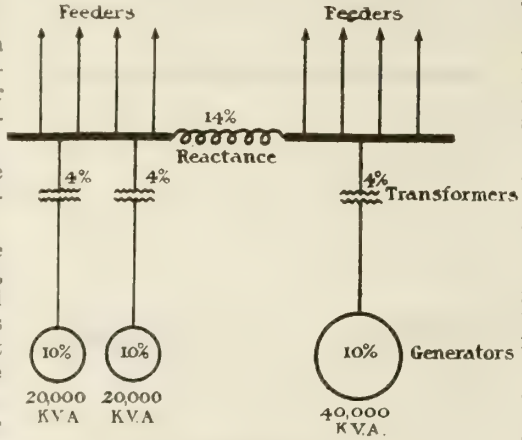

FIG. 5 ILLUSTRATION OF RATING REACTANCES.

circuits will not be disturbed if the voltage does not drop below 50 per cent. of normal at the source. At the first instant the drop will be much less than this, but the generators will be quickly demagnetized and the voltage will approach the limit in less than a second.

If the generators have a short-circuit reactance of 15 per cent. and are furnished with potential regulators, it is likely that they would require a feeder reactance of 33 per cent. based on the generator rating to meet this condition. If now there are 10 feeders (and about the same proportion of spare feeders and spare machines), this requires at full load a feeder reactance of only 3.3 per cent. based on the feeder rating. At times of light load, however, when, say there is only one machine running, the feeder reactance would have to be proportionally higher, so that it is clearly not possible fully to protect the rotary converters all the time, even with reactances in each outgoing feeder.

It should be borne in mind, however, that in modern practice where the mid-point of the system is earthed, all faults to earth will be cleared without serious voltage disturbance, and the large majority of cable faults in particular are of this character. Moreover, the above figures apply only to the worst possible

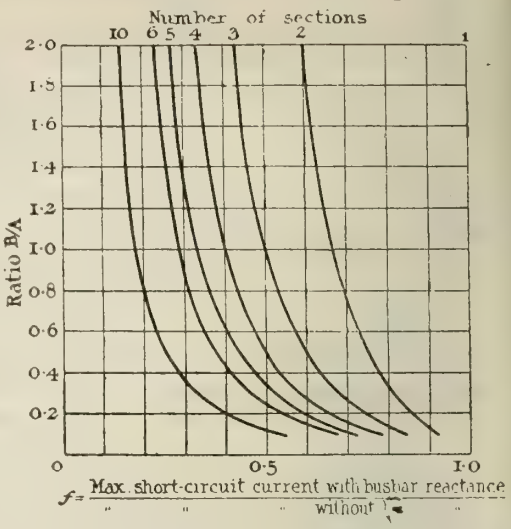

FIG. 6—REDUCTION OF SHORT CIRCUIT BY EMPLOYMENT OF REACTANCES IN STAR.

case, viz., that of faults close to the source.

There is no doubt that the conditions are further greatly improved by the employment of quick-acting switchgear able to clear a fault in one-fifth of a second or less.

Use of feeder group reactances:—A group of feeders running between two common points may be treated as a group and have a common reactance. The number of reactances may be reduced in this way and further protection given to the switchgear controlling individual feeders. The reduction in cost of reactances is partly offset by the additional cost of the necessary group busbar and group switchgear.

Where feeders are grouped only at the source it is better to employ separate feeder reactances rather than group reactances, so that disturbances on any one of the sections fed shall be isolated from the others. In such a case, however, some group reactance may be employed on occasion to protect the feeder switches, as, for example, in incorporating existing feeder switchgear in a larger scheme.

Limitation by Busbar Reactances

The method of employing busbar reactances is intimately connected with the subject of the design and arrangement of the busbars themselves. It is sufficient here to recognize that there are two distinct methods of connecting up the reactances, known respectively as the "star" and "ring" methods and illustrated in Figs. 7 and 8 respectively. It is shown in the Appendix that the star design is generally preferable after considering the operating conditions. Either system will give about equal protection, but here again the advantage in the extreme case lies with the star design.

Sectionalizing the distribution system: It is the system which has to be sectionalized and not the main busbars alone. Clearly the sectionalizing of the busbars is of very little value if the sections are

tied solidly together outside the generating station. This requires that there shall be a correspondence between the busbar sections and the sections of the distributing system. The ultimate plan must as far as possible be pre-arranged from the commencement so that adequate provision may be made in each section of the busbar for the ultimate equipment required by the corresponding section of the distributing system.

The problem as it applies to the main switchboard is simple in comparison with the problem as it applies to the distributing system. It is not possible to lay down general rules for the latter, as the requirements depend so much upon local conditions, but it is essential to have a definite plan in view and to consider each addition to the plant from the point of view of the requirements of the final scheme. It is not necessary actually to sectionalize the system from the commencement into the number of sections which will ultimately be required, but details should be arranged so as to permit of a section being divided into two when it exceeds the predetermined limit. The alternative course will result not in immediate disaster, but in a gradual lowering of the factor of safety until serious trouble points to the cause and necessitates a far more costly remedy. So far as it affects the main station switchgear the problem consists principally in arranging sufficient space for additional circuits on a section and for the ready transfer of circuits from one section to another as the system grows.

Current-limiting Effect:—In considering what results can be obtained by the use of busbar reactance the subject of the transfer capacity required is important, because for a given voltage difference between sections the amount of current to be transferred limits the amount of reactance which can be employed and, therefore, the amount of protection obtainable by this method.

In investigating the limiting effects of different combinations of reactances, the reactance associated with an individual machine, whether internal or external, or in the step-up transformer, is treated as one item, described as generator reactance and indicated by the letter A. The busbar reactances, however connected, are indicated by the letter B. Thus in Fig. 5 A = 14 per cent., B = 14 per cent., and B/A = 1.

Fig. 6 gives a good idea of the results obtainable by the introduction of busbar reactances. The short-circuit current, on the assumption that no reactance is employed, is taken as unity, and the curves show how much this figure is reduced by the employment of busbar reactance. It will be seen, for example, that with B/A = ½ and with five busbar sections the short-circuit currents are more than halved. From the data there given it will be seen, for example, that with five busbar sections, with generator reactance of 17 per cent. and busbar reactance of 6 per cent., it is possible to keep the maximum value of the short-circuit k.v.a. down to three times the plant capacity, instead of 10 times the plant capacity, a common figure at the present day. That is, we build a 100,000-k.v.a. plant in which the conditions will be no more severe than in a present-day 33,000-k.v.a. plant.

Provision of spare machines:—The arrangement of spare plant will be found to be a question which vitally affects the design and use of reactances. If we plan for five machines clearly we cannot employ six busbar sections, or a symmetrical arrangement of three, and if we use four the fifth machine cannot conveniently be connected up as a spare to any one section.

This could be done through the auxiliary busbar, but not without involving complicated switching operations and seriously limiting the flexibility (the measure of flexibility is roughly the number of different simple ways in which one can meet usual and unusual conditions of service).

The number and size of machines should preferably be determined so that with adequate provision for spares the machine capacity will be divided equally between the sections, the number of sections being such as to give the required degree of protection whilst suiting the local conditions.

If the machines are not uniformly distributed as to capacity amongst the sections, certain sections will give much higher short-circuit currents than others, and this cannot well be remedied by using higher reactances with these sections, as the permissible reactance is limited by other considerations.

For reasons previously given it is assumed that there will generally be two machines in excess of the total corresponding to the maximum output; thus, of eight sections, two will be spare. There may be four busbar sections with two each, but the total maximum output will be that of six, and the total maximum output of a section that of 1½ machines. This exercises a large influence on the reactance rating, as it limits the transfer of current necessary.

Transfer of Power:—We desire to transfer power from section to section for purposes of economy, and this transfer may amount to 20 to 70 per cent. of the capacity of a section. This transfer may take place in either direction. For it to take place at all it is necessary to set up a difference of potential between sections, whereas working conditions require that the sections shall be at substantially the same voltage.

The transfer of the energy component of current through the reactance will not require a potential difference greater than is necessary to overcome the ohmic resistance, and this will be some fraction of 1 per cent., perhaps one-fifth with 10 per cent. reactance between sections. To transfer magnetizing current, however, will require a relatively large potential difference, and this will be in fact the reactance drop at the current in question, and this proves to be the limiting feature.

For example, with 10 per cent. reactance between sections, the difference will be 1 per cent. if the magnetizing current transferred is numerically one-tenth of the rated current capacity of a section. That is to say, to transfer this amount of magnetizing current would require that the busbars should be run respectively one-half per cent. above and below normal.

If the load is transferred at 80 per cent. power factor the magnetizing component will be 60 per cent. of the k.v.a. transferred. If therefore this magnetizing component is limited to one-tenth of the section capacity, the load transferred would be limited to 10/6ths of this figure, i.e. one-sixth of the section capacity, whereas we want to transfer perhaps four times this load.

The obvious solution appears to be to transfer the load at a higher power factor and to make up the shortage of magnetizing current by supplying it from the machine or machines tied to the section in question.

In pushing the use of reactances up to the limit it is necessary to utilize this method of maintaining the voltage, but it is not one which should be used under daily working conditions. It involves underloading one or more of the machines, extra care in running adjustments, and in case a fault occurs on the section receiving current, the voltage drop will be greater.

Results Obtainable:—The practical possibilities of this method of control are investigated in Appendix IV., and it will be found that ample protection can be obtained by the use of generator and busbar reactances under normal working conditions without resorting to transference at a power factor above that of the load; but this method can be advantageously resorted to under emergency conditions.

As a result of this investigation it is possible to furnish a table showing results obtainable under practical working conditions, and this has been done in the Appendix.

There is a preponderance of advantage in the use of two unit machines per section, or, of course, the equivalent in smaller machines. If larger units are installed later than were originally contemplated, these may be of twice the size and arranged one per section with suitable reactances and without materially affecting the short-circuit factor.

As a typical example of what can be done we may take the case of five sections and two machines per section. Here with generator reactance of 15 per cent. and busbar reactance of 7½ per cent. we get a short-circuit factor of 3.3 on the maximum output. That is, a station rated to give 100,000-k.v.a. output would give 333,000 k.v.a. on a fault between phases near the source.

Protection of Live Load on Sound Sections:—In considering the use of feeder reactances it has been shown that where a phase-to-phase fault occurs on the load side of the reactance, it is possible to maintain sufficient voltage on the source side of the reactance to keep rotary converters in step.

From what has been said above, it is evident that the use of any such reactances would seriously limit the energy transfer that could be made with any reasonable voltage difference between sections, so it is not possible by this means alone completely to protect running plant attached to sound sections. At the same time it is clear that the use of busbar reactances operates in a helpful direction.

The figures given apply to the sustained short-circuit values. At the first instant, and before the generator voltage is seriously reduced by armature reaction, the busbar reactances have a much greater effect on the voltage on the sound sections.

Cleanliness in the Power Plant

IN going through one of the stations of a large public utility corporation one is forcibly impressed with the immaculate cleanliness of the floors and equipment. The management, indeed, go so far as to warn the employee of his dismissal if caught spitting or throwing matches or cigarette butts on the floor. It may be asked what this has to do with the average power plant where conditions are in many respects different and help perhaps is hard to get? Just this, it is as easy for the engineer in charge of a small plant to enforce cleanliness as it is for those having the operation of the large plants in their care.

The cultivation of habits of personal cleanliness is surely an easy matter and the placing of cuspidors in convenient locations, if spitting must be done, waste-baskets for waste paper and lockers for clothing certainly doesn't cost much and is well repaid in the improved appearance of the plant.

Even when construction work is being undertaken in the plant referred to neatness is strictly enforced and the construction men are held responsible for the keeping of the floors and building as clean as possible.

The proper storing of packing and other supplies is often sadly neglected in the small power plant. Packing costs good money and if it is allowed to lie around on top of the engine room lathe, together with a bunch of ells, tees and what not, it is bound to be the worse for it. Speaking of the lathe, is there no reason why, if one is used at all, it should not be taken care of, the ways greased and gears and other finished surfaces properly protected from rust? It might also be a good thing so far as appearances go to take that burned-out motor from underneath the lathe bed and to remove the accumulation of rubbish that has collected with it.

It might be well to point out that the engineer who neglects the general appearance of his plant is usually as careless in the looking after those conditions which affect economy. An engine covered with oil usually finds the counterpart in the boiler room, in the soot-covered tubes.

Progress of the Oil Engine

THE gradually increasing number of motor ships of various sizes is worthy of note. The oil engine for marine purposes is strongly entrenched in various parts of the world, and Great Britain, at the time of writing, holds the record for the largest ship built fitted with this type of engine. The British built motor has a good record all over the world, and now that the engineering shops are relieved from the stress of war work, a further effort is likely to be made in this class of engine. Sweden is a strong competitor, and the United States are going in for the manufacture of oil engines on quite a large scale. The indications are that a large business will be done in the near future by manufacturers in this line.

Government Control in Britain

WITH the approach of peace, the position of the British mercantile marine is causing considerable anxiety to shipowners in the Old Country. Before the war Great Britain owned half of the entire shipping of the world, and among them a splendid fleet of liners which were the express messengers between the outlying posts of Empire. In their war efforts, the people of Great Britain gave freely of their ships, and their shipbuilding yards were mostly given over to fighting ship construction of various sorts. On Great Britain fell the heaviest shipping losses, and especially on the fleet of superb liners which were her pride. Now that the United States, Canada, France and Japan are all building ships, British shipowners are anxious for the Government to relax its control over them. They feel that, left to themselves, they can once more make Britain supreme on the wave, but if the strangling effects of Government control continue they will be forced out of their proud position forever. It would seem to be the irony of fate, that the country which threw its greatest commercial asset freely into the hazard of war for the benefit of the rest of the world should be rewarded by having her maritime trade taken over by the ships of the nations she saved.

Association and Personal

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS MEET

THE increasing value of a sound, technical education to the plant engineer or other technically trained men was very clearly brought out at the Past President's night of the Canadian Association of Stationary Engineers held in the Temple Building on Wednesday night, November 27th. The founding of this Society in the first place was due solely to a desire on the part of a number of engineers to raise their own educational standards and those of their fellow engineers to a higher plane, and the history of the Association as outlined by A. M. Wickins, the first past president, shows what a factor the Association has been in the improving of the facilities for technical education in Toronto and in the establishing of the Old Mechanics' Institute now long since absorbed in the present technical school system of the city.

The usual business of the lodge was transacted and three new members initiated and at the conclusion of the business session refreshments were served with the oldest past president, A. M. Wickins, in the chair. The Toast Master proposed a toast to the King, and Mr. H. E. Terry proposed that to the City of Toronto, and soid that it was a most pleasing duty. Toronto was possibly the most loyal city in the British Empire and no city had done more towards the winning of the war in the giving of her sons and in the furnishing of munitions to the Allies. Mr. Terry has lived in the city for about 36 years and needless to say Toronto was not as big then as it is now.

In responding to this toast, Controller Maguire stated that it gave him great pleasure to do so. He was born in the city and took a great deal of interest in its development and in this connection wished to emphasize the importance of public ownership and the purchase of Toronto's railway system, which was due in another year or two. It had been said on good authority that if Toronto's street railway were taken over at its scrap value and all modern improvements made on it necessary to bring it to a high state of efficiency, that it would be paid for completely in ten years' operation. The housing problem was also a serious one for Toronto and the question of wages after the war and other reconstruction problems were dwelt upon at some length.

A matter touched upon by Controller Maguire which was of great importance so far as the engineers were concerned was the recent appointment of a man with no engineering credentials of any kind to the position of foreman of the filtration plant at the City of Toronto Water Works Pumping System. This was characterized as a most unwise policy for any city to attempt. The importance of having men capable of the wise operation of steam plants in charge of works of such nature was very strongly emphasized.

The toast to the technical press was proposed by Mr. G. D. Bly, and responded to by B. G. Newton and A. R. Kennedy. Mr. Newton in replying emphasized the importance of the technical press during the last four years of war activities. The men and engineers of the country have been seeking information as never before from the columns of the technical press along all lines. The cost of preparing information and publishing literature of this nature was very great and the advertising pages were almost the sole source of revenue.

An interesting item of news was given out in the information as to what "Canadian Machinery" had done during the war, in the help it had extended to the munition business. It was the first in the field in Canada, and not only Canadian and American technical papers followed it very closely, but those of Europe and Australia and other allied countries were in constant communication with "Canadian Machinery." To such an extent was this the case that the Australian Shell Committee went to great expense to reprint completely one special shell number of "Canadian Machinery" and distributed it amongst all munition shops in Australia as a text book on the subject.

A number of French officers were in Canada recently inspecting the shell shops here and paid a high tribute to the excellence of the work turned out, the quantity produced and the general design of the machine shops as a whole. They stated that there were few shops in England or on the continent which could compare with the Canadian shops in these respects. A matter of special importance touched upon was that of the relation of the technical paper to the readers of it, and particularly the contributors, and the great advantages of imparting information to the paper through contributing to it were dwelt upon.

Mr. Kennedy spoke in part of the interesting work of the editorial management of technical papers. The character of the work was very much more substantial than that of the daily press.

It was one of the most interesting things to study men and to analyze the qualities which lead to their success, in many cases, in spite of extreme poverty and the lack of advantages in their early education. In general it might be said that a man owed his success in his chosen profession to a combination of four things — the first was the night school, the second the correspondence school, the third the technical press and books and the fourth determination. It has always seemed wrong that a man should be forced to leave school at an early age and, lacking the advantages which others possessed, had to study for long hours at night, plugging and working alone by himself for education which, after all, was really his by rights, and which should have been provided him before he made his plunge into the serious task of earning a living.

The engineer of to-day had a very serious load of responsibility placed on his shoulders. The conservation of fuel was still uppermost in the minds of those who govern the various Allied countries and even though the war were over it was still a very serious problem. The majority of engineers fully appreciated the fact that fuel saving was an important item and conservation to them was a very desirable object, but in many cases plant owners and those in authority were still very blind to the fact that appliances for efficient operation were needed before coal could be saved.

Mr. Fenner, associate editor of "Canadian Machinery" and POWER HOUSE, gave a very acceptable rendering of the **"Admiral's Broom"**

Brother W. C. McGhie, in proposing the toast to the Canadian Association of Stationary Engineers, stated that the question of appointing engineers with no certificate qualifications to positions of importance on civic and municipal works was something with which his department had very much to do, and the particular case cited by Controller Maguire had never been brought to his attention by engineers or others; however, it would be looked into. The issuing of certificates to engineers was an important matter and the C.A.S.E. was

a most important factor in the education of the engineer to appoint where he was capable of fulfilling the most important positions. The growth of the organization was dwelt upon and it was stated that whereas 10 years ago the membership was only in the neighborhood of 4,000, it now numbered 12,000, and was increasing very rapidly.

The important question of graded certificates and graded plants, was one which was very likely to come up some time in the near future for settlement, and it was hoped that some equitable and satisfactory arrangement would be reached.

A. M. Wickins, or as he is more familiarly known by the members of the C.A.S.E., Dad Wickins, gave some interesting facts about the organization from its inception over 30 years ago. It was originally the conception of a number of the engineers of that time to get together and form an association for the mutual improvement of its members.

The education of the engineer was recognized at that time as being one of the most important features of the organization which could be formed for his welfare, and in consequence as a model or emblem for the Association an arch was chosen with the keystone knowledge and the two cornerstones of integrity and reliability as a self-standing feature. No politics, religion or other controversial matters ever entered into the organization's plans or meetings of any nature.

During the course of the years the Association had got along remarkably well and had considerably raised the standard of the engineers throughout Ontario. It was recognized that much of the Association's usefulness to the engineer could be extended in the locating of positions for any particular engineer, and on entering the Association an examination was give to the engineer for his classification, so that in the event of a position being available the proper engineer could be found to fill it. After the Association had been in existence for two or three years it was found advisable to incorporate it so that it could hold property, and be conducted in a business-like way. Lodges were formed outside of Toronto and the status of the engineer improved eventually by the obtaining of the permissive license law whereby engineers were granted licenses for the holding of the Ontario certificates.

The engineer has a very serious responsibility on his shoulders, and might even be said to have more responsibility than the average doctor—for the doctor when he gives the man the wrong medicine and the man dies can very easily say that it was a case where the man would have died in any case, but the engineer is responsible for his every mistake.

A little known fact about the Association is that it was the original means of starting Toronto's Technical School system, and a great factor in its development to which it is to-day. No. 1 class started the first technical school in the old Wycliffe College, where five teachers were engaged for five nights a week and six months in the year. The equipment was purchased and teachers obtained from the School of Practical Science, and it was expected that on the first night 150 scholars would be obtained. The immediate popularity of the innovation was seen on the second night when 277 applications were made for admission to the classes. The Old Mechanics' Institute, as it was known, was in a few years' time organized, and at one time eleven hundred scholars were in attendance with day and night classes in both commercial and engineering subjects. The organization had certainly done a lot for Toronto's education and necessarily much of this was not appreciated by the public at large.

The Operators' Point of View

HOME-MADE TOOLS FOR THE ELECTRICAL REPAIR MAN

BY MAURICE CLEMENT

IT is surprising to note the large number of homemade tools one can see in an electrical repair shop; the fact that none of these tools can be bought ready-made, but must all be specially constructed, gives them an interest that is lacking in all standard tools; everything from a coil taping needle to an armature banding tension block, can be seen among an armature winder's tools.

For the benefit of those who are interested, I shall go into detail concerning these tools. The first, and most simple, is the "coil taping needle." This is made of a length of No. 14 banding wire, as shown in Fig. I. As only one foot of the wire is used in making the taping needle, it can be had at a very low cost; the taping needle is used for taping coils in closed slot stators, and when the user becomes accustomed to it, much speed can be attained, thereby saving considerable time.

The coil raiser, also in Fig. 1, is simply a piece of steel, 16 inches long, 1 inch wide, and 3-16 inch thick, with a 4-inch one-sided taper to it on one end. This tool is used mainly in stripping open slot armatures and stators, but can also be used to good advantage in removing grounded coils sufficiently to allow for insulating a weak spot in the coil, the main object being, in this case, to lift out a tight fitting coil without damaging the insulation.

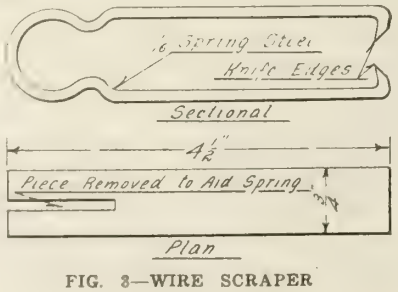

FIG. 3—WIRE SCRAPER

Fig. 2 shows the armature sling, which is made of a piece of 1-16 inch sheet iron, 2 feet long and 10 inches wide; at each end is a steel triangle, made of a ¾-inch steel bar, for hooking on to a crane. Without this sling, a rope or wire cable strap would be used, with the danger of springing the shaft; in a recent test this sling has held a weight of one ton, without apparent strain.

The wedge-drift is a piece of tool steel 8 inches long, ⅝ inch wide, and 3-32 inch thick; over which is fitted a loose fitting steel sleeve, 1-16 inch thick The wedge-drift is used for driving fibre wedges between top of coil and lamination overhang in closed slot machines; to use the wedge-drift most efficiently, the fibre wedge must first be inserted about a quarter-inch into the

slot, then with the drift pulled back in the sleeve, fit the sleeve over the wedge and drive to the proper place; the sleeve holding the wedge in its position properly and preventing breakage.

The wire scraper, Fig. 3, is one of the best little time-savers of the whole lise. In ordinary circumstances a knife is used to scrape wires prior to connecting, but with the rough treatment a knife receives in scraping wires, its life is very short, necessitating frequent renewal of knives and incidentally, added expense. The wire scraper is made of spring steel and is primarily 1 foot long and ¾ inch wide; before bending to the desired shape, grind a knife edge on each end and cut out a piece 2 inches by ¼ inch from the centre.

After bending to proper shape, knife edges can be retouched with a file. The open space, which is now at back end of scraper, gives a greater spring effect and allows knife edges to be brought together with a minimum of pressure. In Fig. 4 we have the cell shaper, which, when we take into consideration the valuable work it does, is well nigh indispensable to any well regulated repair shop; the base of the cell shaper is of hard wood, in this sase being maple; it is composed of two pieces, one being 16 in. x 4½ x ¾ in., the other is 16 in., x 2 in. x ¾ in. These pieces are hinged together on the long edge.

Where the two pieces of wood meet, a half-inch metal strip is piaced. This strip is shaped at the ends so as not to interfere with the action of the hinges, and held down by screws; between the hinges the strip is raised sufficiently to allow the inserting of a reasonable thickness of fish-paper.

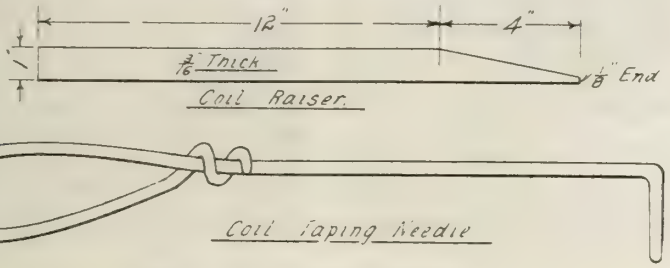

FIG. 1—COIL TAPING NEEDLE

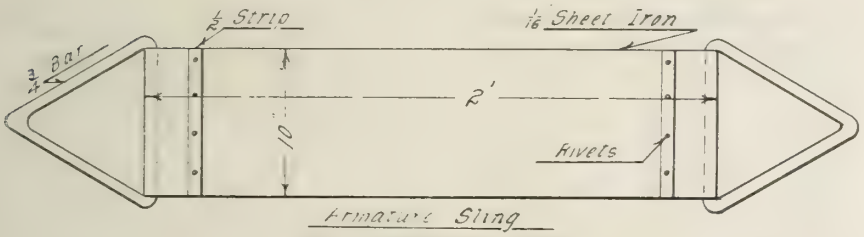

FIG. 2—ARMATURE SLING

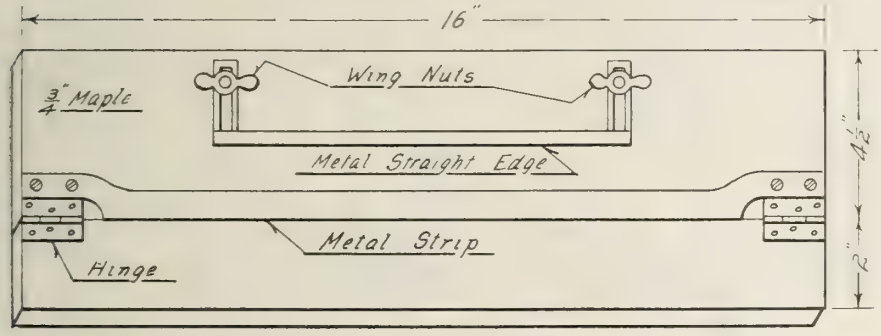

FIG. 4—CELL SHAPER

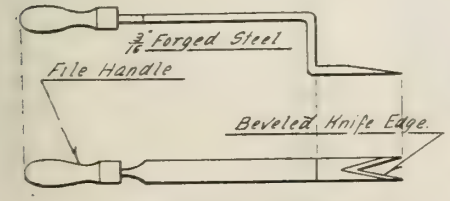

FIG. 5—CELL CUTTER.

Behind the metal strip is an adjustable metal straight edge with wing nuts to hold it in place; to make a cell for a closed slot stator or armature, length of slot must first be determined, allowing for a short projection. Next, height of slot, measuring from bottom of slot to bottom of lamnation overhang; width of slot at the bottom must also be determined. This gives us the following:—

Length of slot + projection = one dimension.

Height of slot x 2 + width at bottom = other dimension.

In cutting the fish-paper for these cells, it must be remembered that there is a proper and improper way of doing it; the grain of the paper must be taken into consideration. The right way to cut it is to lay out the first dimension with the grain and the second across the grain. In adjusting the cell shaper, the distance from the forward edge of metal strip to the metal straight edge should be equal to the height of slot.

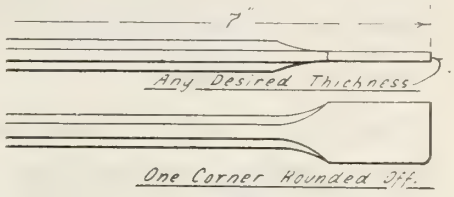

FIG. 6—DRIVING DOWN TOOL

To shape cells, insert fish-paper under metal strip until it is squarely against straight edge and turn hinged base on hinges; this will make a neat fold in the paper; turn paper around and make another fold on opposite side, all is now ready to use.

In Fig. 5, the cell cutter is another very simple, but very effective tool. It is composed of a piece of forged steel, 14 inches long, ¾ inch wide and 3-16 inch thick, with a set of bevelled knife edges at one end and a file handle at the other; the handle is raised so as to allow free movement of the cutting end. It is used in cutting projecting insulation from slots of open slot windings after coils have been assembled.

In Fig. 6 we have the driving down tool, which is nothing more than a thin bladed chisel, with the end squared off. It is used for driving down leads into commutator slots. It is advisable to have four or five chisels with various blade thicknesses, to provide for different sizes of wire. The armature banding tension block, shown in Fig. 7, is a device which does away entirely with the necessity of a banding lathe; in the

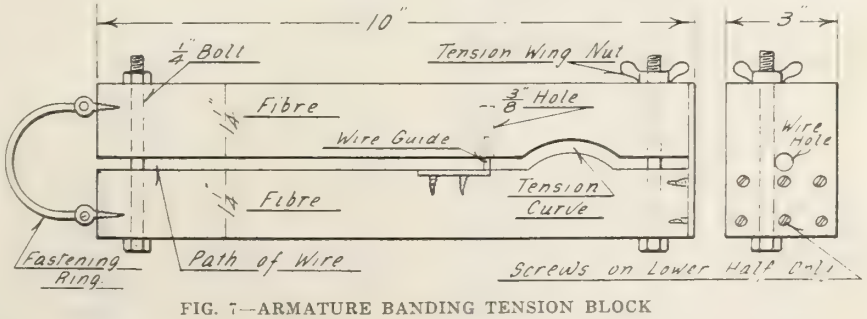

FIG. 7—ARMATURE BANDING TENSION BLOCK

WHERE DOES THE ENERGY GO?

SCIENTISTS tell us that by the principle of the conservation of energy no energy is ever created or destroyed. The editor of POWER HOUSE recently had an interesting paradox, which he is passing along, propounded to him which bears upon the above law of the conservation of energy. Let us suppose a spring of steel bent in such a manner that work is done in the storing up of potential energy in the spring. Furthermore suppose this spring to be clamped in such a manner that it retains its stored up energy and then let it be placed in an acid bath so that it will be eaten away uniformly by the acid. The question arises as to where the stored up energy goes and what becomes of it. The arrangement of the mechanism is of small importance so long as the spring is eaten away uniformly and does not suddenly break. Perhaps some of our readers would like to take a fling at the problem. If so let us hear from you.

small shop, where the armature winder does his own banding, the tension block is an innovation worthy of notice; the armature does not have to be removed from the stand to be banded.

About one foot of stout line with a hook lashed to one bed is made fast to the fastening ring on the tension block and hooked to an eye bolt, which is set in the floor for that purpose. The spool of banding wire is placed on a small stand beside the eyebolt; the wire passed between the two blocks at the rear end, through hole in first wire guide over tension curve, and through second wire guide hole, thence to the armature.

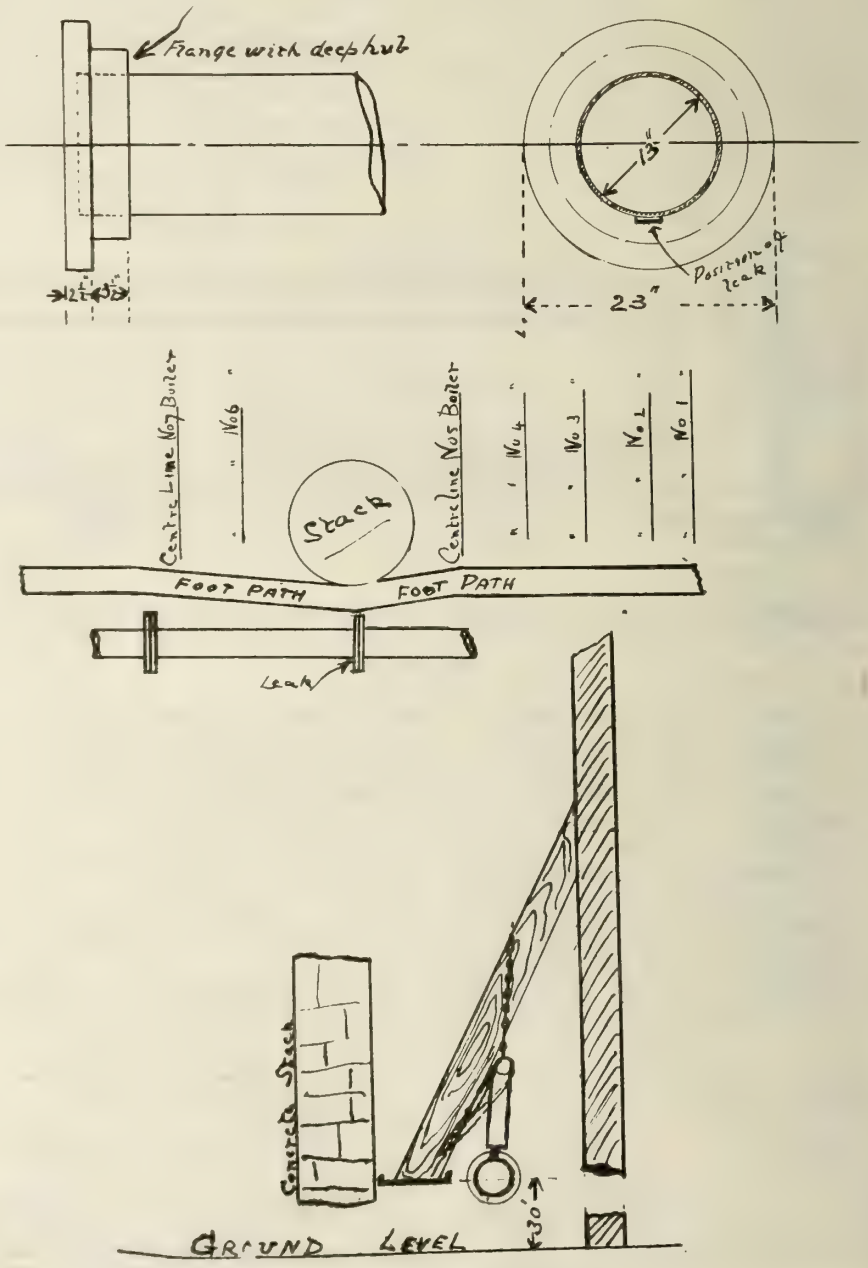
The tension can be regulated by the wing nut at the forward upper end of the block; by screwing down the wing nut, both sides of the block are brought nearer together, thereby narrowing the tension curve over which the wire must pass, this increases the resistance on the wire and incidentally the tightness of the band; a pipe wrench is used on the shaft to revolve the armature. It will be noticed that the forward end plate is screwed down to the lower half only, so as not to interfere with the tension wing nut and bolt.

REPAIRS TO MAIN STEAM HEADERS

T. H. F.

The writer, while in charge of a steam plant, had occasion to make some repairs on a 14" main steam header, which may be of interest to readers.

The boiler plant consisted of seven B. & W. boilers, six of them being 250 H.P. and one 125 H.P. The main header was 150 feet long, and was 12" dia. at No. 1 boiler, increasing to 14" o.d. at No. 2 and carried along the rest of the length at the same diameter. The boilers were arranged in pairs, except No. 1, all boilers being numbered from the right to left. Thus No. 1 was separate, No. 2 and 3 together, No. 4 and 5 together, then a 22 foot space containing the feed pumps, heaters, etc., and No. 6 and 7 boilers together. Steam for main engines was taken from the header at right hand side of the stack, and at the far end of the line the 80 lb. reducing valve was fitted, distributing steam to all factory heating lines, and some of the auxiliary machinery. Steam for circulating and dry vacuum pumps was taken from main header at left hand side of stack, while the main feed pump steam was taken from header on short length situated immediately behind stack. It was on this length that the first repair was made. A bad leak had developed at some time previous to the writer's taking charge, in the thread of the pipe, and the pipe had been taken down, and flange screwed up. This, as far as could be learned, had been repeated on two or three occasions, after which the leak would stop for a while. When the writer took charge, the leak was pretty bad, and getting worse all the time. It was plainly a case of taking the pipe down, and keeping it down long enough to make a permanent repair. The plant had to keep running in the meantime, so it was decided to have two blank flanges made, and blank the main header off after the pipe was taken down, and running the boilers on each side of the break as a separate plant. Thus Nos. 1 to 5 were



REPAIRS TO STEAM HEADER.

available for main engines, and Nos. 6 and 7 had to carry the auxiliaries, steam for factory, lubricating pumps for main engines. The connection for the feed pump being on the piece of the header to be taken down, as was also the steam supply to lubricating pumps, provision had to be made for these, on another part of the header. As there were convenient plugs in header, this presented but small difficulty. The flanges were made, and necessary valves and fittings procured for alterations. One feature of the job was the awkward position of the header for any handling. It was about 30 feet above the ground level, and from the header to roof trusses of power house was about 35 again. The header was supported on rollers, on a steel framing, and the only provision for getting around was a footing made of a 12" channel, laid flat with flanges looking up. No provision of any kind had been made for tackle, to lift the pipe or valves, as evidently repairs were thought by the designer to be unnecessary. One end of the length to be taken down, came right behind the stack, and close up to it, so that the footway had to be angled to pass it. Owing to the roof trusses being pitched 17' apart and being so hard to reach, the use of them for lifting tackle was out of the question. The method adopted was to place 6" x 6" timber from footway to wall, and hang the tackle from that. Chain blocks were used till all bolts were out and pipe lowered down clear, when rope blocks were made fast, and pipe lowered to the ground. The blank flanges were put on, connections made to feed pumps, etc., and steam put on to the two separate headers. I may say that we had practically no trouble in operating this way excepting that the firemen, at first, would have trouble in feeding their respective boilers. This was because the man on Nos. 6 and 7 would allow his steam to drop below the working pressure, and his check valves being open, the pump would feed all into 6 and 7, and none to the other battery. After a while the firemen were made to understand this, and there was no more trouble.

The pipe on examination was found to be pretty badly cut in the thread. In fact, a slot 1½" long by 1/16" wide, was cut right through the thread the full thickness of the flange. To get over this, it was necessary to cut the bad piece off altogether. To make up what was cut off the length, a pattern was made, and a flange cast with a long hub, so that the pipe and flange when made up would be the same length as the original. The pipe being 10 feet long, and the biggest lathe we had being only nine feet, the thread cutting looked like being difficult. However the tail stock was taken off the lathe, and a wooden block put on to carry the free end of the pipe. A steady rest was put in the centre and the end to be repaired was held in the chuck. The new thread was cut starting from the end of the old, and cut as nearly to size as possible, and then the bad end was cut off. The flange was then put on the lathe and bored and screwed, the pipe being fitted in while the flange was on the lathe. It was fitted so as to go up about half way on the thread by hand, and then tightened home in the usual way. Special care was taken to get the correct length and particularly to get the holes in line with the holes in the other flange. This was done and the pipe was ready to put up which was done on the following Sunday. When I left the plant two years after it was still perfectly tight.

Another length was repaired in the the same way but owing to it being the length connected to Nos. 6 and 7 boilers, it was necessary to make provision to keep the header continuous while the repair was being made. This was done by taking the blank flanges previously used and boring them out to take 6-in. pipe. A piece of 6-in. pipe the requisite length was procured and the flanges screwed each end. This pipe was then put up in the place of the main leader length and though so much smaller, did fairly satisfactory work while the repair was carried out. The only difficulty was that the pressure on the low pressure side of reducing valve was some 10 lbs. lower than normal. This was not of great importance for the time necessary to make repairs.

OPERATOR ORGANIZATIONS

British Columbia Association of Stationary Engineers, Vancouver.—Subordinate Lodges at Vancouver, Victoria, New Westminster, Cumberland, Merritt, and Fernie.

North-West Association of Stationary Engineers, Edmonton, Alta.

Manitoba Association of Stationary Engineers, Winnipeg.

Canadian Association of Stationary Engineers, Hamilton, Ont.—Subordinate Lodges at Montreal, Toronto, Hamilton, Ottawa, Brantford, Guelph, Kitchener, Chatham, Ont.; St. John, N.B.; Owen Sound, London, Stratford, Belleville, Kingston, Sudbury, St. Thomas, North Bay, Port Arthur, Sarnia, and Windsor, Ont. The executive officers of the C.A.S.E. Grand Lodge are as follows:—

Past President—W. G. Forbes, Montreal, Que.
President—R. F. Gofton, Kitchener, Ont.
Vice-President—Wm. Cooke, Belleville, Ont.
Treasurer.—A. W. Heath, Hamilton, Ont.
Conductor—S. Balmfirth, Toronto, Ont.
Doorkeeper—George Moll, London, Ont.
Secretary.—John H. Hale, Hamilton, Ont.

RUST-PREVENTING VARNISH

Resin six parts, sandarac nine parts, gumlac three parts, turpentine six parts, and rectified alcohol nine parts. The resin, sandarac, and gumlac should be mixed together in a pounded condition and then carefully heated until melted. When they are well melted the turpentine should be added very gradually, stirring all the while. The mixture should then be digested until dissolution takes place. Then add rectified alcohol up to the amount stated above. It should afterwards be filtered through a fine cloth or thick filter paper, and preserved in well stoppered bottles so that no evaporation can take place.

SUGGESTION FROM WEST

A proposal that Alberta and Saskatchewan deposits of low-grade coal, which will not stand shipment by reason of its friability, be utilized for the generation of electricity for light and power, has been made to the Advisory Council for Industrial and Scientific Research by Hon. C. A. Dunning, provincial treasurer of Saskatchewan. The suggestion is that power houses be erected at the mine fields and the current be distributed to farmers and other consumers. The proposition has been referred to the council's lignite committee for investigation.

CRITICISM OF EACH OTHER'S WORK IS BOUND TO PRODUCE RESULTS

Dear Sir: In answer to your correspondent A. L. Haas, re line shaft repair. I quite agree with him in the cast of the shafting being of a light nature, and also, the work being the same, the ways and means mentioned would have been all right. As a matter of fact I have run a line shaft break with the aid of two lathe dogs with holes countersunk in the shafting to accommodate the set screws, but be aware it was in the case of a shafting 2½ inches diameter, also with setting shafting collars up tight against the hanger bearings. For a shaft of 6 in. diameter you are not always in a position to pick up a coupling of the above diameter and cutting the keyway would take almost as long as cutting same as I mentioned, and would also have had the trouble of losing about three large pulleys that were dead against the face of the hanger bearings and sliding; in any case one length of the shaft back to put on the coupling. As to solid drawn tubing that is out of the question in this case as I consider I would have a lively time in securing tubing of this size, and I think that it would not stand up to the work it had to do.

The pulley boss would be all right in some cases as I have also used this means of repairing a shaft, not a line shaft but one in a machine.

I must mention that in the case of the pair of collars the break was a direct and nearly even twist break as we found the same had been fractured for some time, as I should say 1-5 of the way through the break it was very rusty, which clearly shows my above statements to be correct.

If I am not mistaken I think the repair took us about nine hours or thereabouts.

I am pleased to know your correspondent took an interest in contradiction as to my method as it shows other ways and means of doing the job, and I have always maintained that if there were more of these good-natured criticisms of one another's work it would be much better for all concerned. Trusting I may have the pleasure of sometime renewing the acquaintance of Mr. A. L. Haas.

A. H. HOULDSWORTH.

"Hector" Comes Back—from a Seven Mile Hike

Seven miles through the tubes of Heine, B. & W., Hunt and Poole Boilers—

That was Hector's stroll.

Seven miles of tubes he cleaned of scale, and came through without even having to have the cone cutters on the flexible head removed!

No wonder Hector is called the "Bulldog Cleaner."

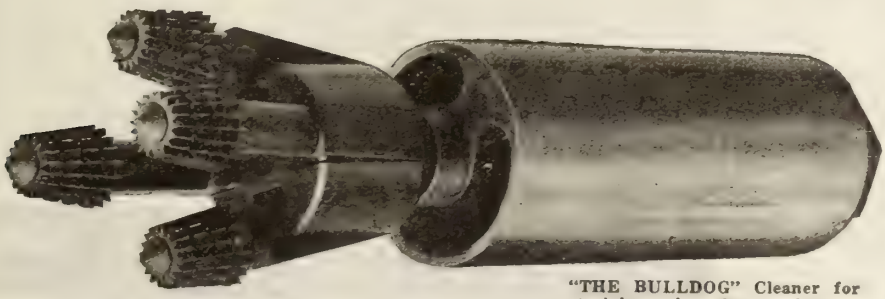
He is a "Bulldog" for strength and endurance—a "Terrier" for work.

Let him into your plant — sic him onto scale — watch him conquer.

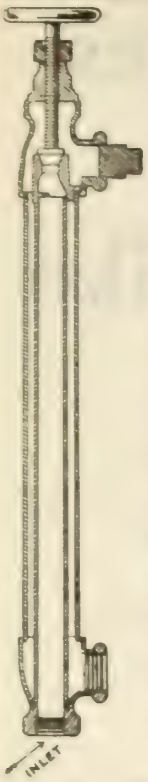
The "Bulldog" is one type of Liberty Cleaner. There are others to meet all needs. Write for Catalog "H."

Liberty Manufacturing Company

443 Diamond St., Pittsburgh, Pennsylvania



"THE BULLDOG" Cleaner for straight tubes—3½ and 4-in. sizes—also made for bent tubes.



The LONG Patent Steam Trap

Automatically drains jacket kettles, separators and steam mains. Nine hundred to 1,500 feet of one-inch pipe isn't beyond its ability. Also used with splendid success in drying room systems.

Only One Movable Part

Works against 1 and 200 pounds of pressure—no possibility of freezing. Has two outlets so it can be installed in any position.

Circular gives full particulars.

Write to-day.

Orders For a Year.—President J. J. Harty of the Canadian Locomotive Company, Kingston, states that the company has at present orders on hand to keep it busy for a year, and he expects the plant will be taxed to the utmost for several years to overcome transportation difficulties. At present there are more than 1,000 men employed, and the company is giving every consideration to returned soldiers.

Canadian Car and Foundry Reorganized.—The work of reorganization at the Canadian Car and Foundry Company's plant at Fort William, Ont., is now completed. H. Frawley has been appointed superintendent and is now in full charge. The company is now engaged in filling a contract for 450 cars and has also 1,000 repair orders to execute. Since the temporary closing down of the shipbuilding plant and the recent departure of the last of the French mine sweepers, there have been considerable reductions in both the administrative and operative staffs, but there is ample work on hand to find employment for five hundred men during the whole of the winter.

Skilled Men Needed.—"Shell men and munitions workers do not seem to be able to fill the positions which we have. We need machinists and skilled workers of the type prior to the outbreak of war," said Mr. W. C. Hagen, secretary of the Machinists' Union. In the offices of the organization was an order for fifty skilled workers, with the request that they be on their way to their work, which was out of town, by this morning. There were other orders for workers of this type, and it was stated that many industries were experiencing considerable difficulty in obtaining the labor now required. There is also a demand for molders and boilermakers. For skilled work the same wages are being paid as during the war.

Faculty of Aviation.—The governing bodies of the Canadian universities, having decided to add faculties of aviation to their curriculum, there will be a chair of this modern science at Toronto University. According to a statement made by an officer of the R. A. F., the University of Toronto will receive three 'planes, two for instructional purposes and one for flying. Other universities will receive a like number. Except for a few Curtiss machines they will not be used for actual flying, but for the teaching of aviation. The greater part of the course will be taught by the mathematical professors, as the theory of aviation depends on the working out of mathematical problems. At first thought it would appear that qualified flying officers would make ideal teachers in this department, but to teach the theory of aviation a high knowledge of mathematics is necessary, while in actual flying, nerve and ability to think and act quickly is paramount, and the most successful aviators are possessed of the latter rather than the former qualifications. Any aviator who has these three can command a higher position than that of professor.

Not Looking For Work.—No particular rush of women for domestic or other employment was noticed at the Ontario Government Employment Bureau. It was very probably due to the fact that a very large number of the girls who had been in munition work were of the class who did not need to work for a living, but had done the work simply to help on the war, consequently since the armistice had been signed they had ceased from their labors, and were not looking for anything else to do. Women whose husbands were overseas had also been in the munition factories, and these also were now no longer anxious to work in view of the fact that they were looking forward to the return of their husbands, and would be glad to remain in their own homes. There are plenty of positions vacant in domestic work and as workers on farms, and there is still difficulty in getting people to fill them. Therefore the domestic situation has become no easier since peace was declared, and the majority of those who do apply for domestic work are asking only for day labor, and have no desire to take permanent residential work.

Dissolve Commissions.—Several commissions which have exercised important functions at Ottawa during the war are in the gradual process of dissolution. The War Trade Board will shortly be wound up. It has had charge of the import and export restrictions, acting in co-operation with the similar body at Washington. Under its direction the import business for some months has been largely on a license basis. Most of the restrictions are still on, but they will be removed from time to time, and when the war is officially over all probably will go. The War Purchasing Commission is another body which, as at present constituted, will likely disappear. Its members, Sir Hormisdas Laporte, W. P. Gundy and George Galt, have been giving their services free, and will probably retire by return to their

SALES ENGINEER—PRACTICAL OR TECHnical engineer as salesman for high grade line of power plant equipment by largest concern of its kind in the country. Most unusual opportunity. Prefer man who has established a sales record, but will consider one without experience, provided he is properly qualified. Give details and record of last three positions held and salary expected to start. Box 151, Power House.

WANTED—BOILER ROOM ENGINEER, FAmiliar with modern methods of boiler room operation and capable of using instruments for testing. Location western Ontario. None but first-class men need apply. Box 150, Power House.

MONCRIEFF'S "UNIFIC" WATER GAUGE GLASSES

(Canadian Representative)

private affairs. Another body will be created to direct all Government purchases for the different departments. The Food Board is now a one-man affair, Chairman H. B. Thomson is carrying on, but the other members, Messrs. Dunning and McGregor, have retired. The restrictions are being modified from time to time, but the work will be continued at least till peace is declared, and probably for some time after, the problem of feeding allied, enemy and neutral countries not yet being solved. The Imperial Munitions Board, whose contracts are being terminated, is fast reducing its staff, but it will take fully three months to wind up the business.

DRIVING BELT OF IRON WIRE

The shortage of leather and textile fibres suitable for making up into driving belts, has produced a new industry in Austria, which may be worth while noting. These belts are now made of iron wire in some instances in combination with paper twine. The standard type consists of double iron wire, spirally twisted together, and in part slightly copper-plated by a chemical process. They range up to about 10 cm. broad. Another sample is of wire gauze strips interlaced with one-ply and two-ply paper yarn, partly with single and partly with double threads. It is bound at the edges with paper yarn, then strongly impregnated with tar asphalt, and flattened out between rollers. A third sample is bound with iron wire spirally twisted.

OLD-FASHIONED PAINT REMOVERS

The following recipes for alkaline paint removers are of the old-fashioned type; the modern quick process paint and varnish removers, while doing this work very well, and indispensable for refinishing wood in the natural, are entirely too high a price for use in removing paint on surfaces to be painted over. The recipes are as follows:

Dissolve 40 lb. caustic soda, 98 per cent., in 5 gallons of water. Take 8 lb. fine whiting and 4 lb. corn starch, and mix with 1 gal. of the caustic solution to form a paste; apply with an old brush, and leave the paint on for about twenty to thirty minutes. When the paint has softened, wash off with water, using a scraper where required. Will also remove varnish.

Another very good formula is: Mix 7 lb. of caustic soda, 98 per cent., with 15 lb. warm water; mix 1 lb. corn starch and 11 lb. china clay with 1½ gallons of water, adding to it the caustic soda solution, forming a paste that must be beaten until free of lumps. Apply freely to the surface with an old brush and permit it to remain until the paint or varnish has lifted, then scrape and wash off with warm water. Wall paper can also be removed in this manner, when the remover is further diluted with water. For cleaning painted surfaces, use a weak solution of the remover.

Operators, whose hands are easily affected by strong lye or soda solutions, should wear rubber gloves while working with the remover. In order to neutralize the alkaline nature of the remover a small portion of vinegar can be added to the water used for cleaning off, say 1 gill to each gallon of water.—M. M.

SHAFTING QUICK TO CATCH CLOTHING

Great Care is Always Necessary to Guard Against Any Accidents.

By J. H. R.

The statement that an oiler employed at the Hochelaga power plant of Montreal Tramways Co. was recently killed by being swung around a driving shaft and dashed to the concrete floor, only emphasizes the fact that the greatest precaution must be continually exercised when men working in close proximity to rapidly moving shafts or machinery. The presence of oil on a revolving shaft is always an attractive force for loose parts of clothing, and little warning can be given when a shaft takes hold of some portion of the wearing apparel.

We would recall a instance where the driving shaft of a geared draw press was located at the rear of the machine, at a height of about five feet from the floor. When setting or repairing draw dies it was frequently necessary to stoop beneath this shaft to reach the work, and the writer himself has had cause to remember this shaft, as it has been the means of pulling a few odd hairs out of a well cropped head. Chances should never be taken where risk is imminent. Play safe.

THE LARGEST MOTOR BOAT

The largest and most powerful motor ship yet produced anywhere was, in September, put through her speed trials on the Clyde. This is the twin-screw Deisel-engined "Glenapp," of 10,000 tons deadweight carrying capacity, and 6,600 total engine power, developed in two sets of eight-cylinder, four-cycle Burmeister and Wain (Diesel) Oil Engine Co., Glasgow. The vessel herself was built by Messrs. Barclay, Curle and Co., Whiteinch, who previously were associated with the Burmeister and Wain works, and were pioneers in Great Britain in the matter of motor ships. All the engine room auxiliaries of the Glenapp, also all deck machinery, including the steering gear, are electrically driven, the power being generated by two auxiliary Diesel sets in the engine room. A small oil-fuel boiler supplies steam for heating and cooking systems, and for fire-extinguishing purposes. The oil-fuel is carried in the vessel's double bottom, the space generally occupied by side and cross coal bunkers being thus available for cargo. It may be added that Messrs. Barclay, Curle & Co., Ltd., during September, and within a period of ten days, delivered to their owners, two merchant steamers of a total deadweight carrying capacity of 20,000 tons.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 TO 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done — give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

Electrical Engineers Meet in Toronto

Interesting Canadian Developments in Electrical Engineering Described at Meeting Held Under the Auspices of the Toronto Section of the American Institute of Electrical Engineers

THE development of Canada's waterpowers, the features of design being developed for transmitting electric energy, and the electrification of her railways, formed the interesting subjects of papers read before the 344th meeting of the American Institute of Electrical Engineers, held in Toronto, Friday and Saturday, Nov. 22-23. This meeting has a special interest for the engineering profession of Toronto, in that it is the first meeting of the main society ever held here under the auspices of the local section.

Members were present from various points, New York, Philadelphia, Niagara Falls, Erie, Pittsfield, Pt. Huron, Schenectady, and other points including Austin, Texas.

The afternoon session, Friday, was opened by the chairman, Arthur H. Hull, who, in his address, welcomed the American delegates. F. L. Hutchison, the secretary of the A.I.E.E., in the absence of the president through war activities, responded. The Toronto section was one of the first local sections organized. The plan of establishing local sections was first brought forward in 1902, and this section was organized in 1903. It is one of the few that has kept up its activities during the war to anything approaching pre-war standards.

In a paper read by Arthur H. Hull on "Electric power generation in Ontario on systems of hydro-electric power commission." the progress to date of the municipally-owned system was outlined.

Ontario has developed into the greatest manufacturing province in Canada, and as there are no coal deposits its abundant waterpower resources are being more and more utilized to furnish the power required for its varied industrial developments. About 702.000 horsepower are developed in Ontario at present, leaving a total of 4.227,000 horsepower still available. Of the above total for power developed, about 69,000 horsepower is used in pulp and paper manufacture, about 59.000 horsepower is used as hydraulic power directly applied, and teh balance, 574,000 horsepower. is converted into electric energy for light and power. The commission now own and operate ten systems in the various parts of the province from Port Arthur to the Rideau and St. Lawrence, and as far north as Nipissing Village. The various systems were described in detail and data given on the new Queenston development now under way, as well as on the extensions now being carried on at the Ontario Power Company plant. In connection with this latter, the speaker stated that the two new generators of 15,000 kva. rating each. were made in Canada, with the exception of the steel laminations and insulation. This speaks well for Canadian industry under war conditions.

The second paper read on Friday afternoon by Mr. W. G. Gordon on the "Electrical equipment of the Canadian Northern Tunnel in Montreal." This work is one of the most important that has been undertaken in Canada of recent years, and the features of electrical design dealt with in the course of the paper were of unusual interest. Following a description of the tunnel proper and the terminal conditions which had to be dealt with, the author entered into a detailed description of the electrified portion of the track ten miles in length. It is later proposed to extend this electrification of the railway to Ottawa, and the substation feeding the system was located with this fact in mind. Power is obtained from the Montreal Light, Heat and Power Co. at 11,000 volts and 60 cycles, and by means of motor generator sets, is distributed to the railway feeders at 2,400 volts direct current. This voltage is the highest that has been used in Canada up to the present time for this work, and was chosen in view of the contemplated extension of the system.

Three types of traffic had to be considered in planning the equipment: passenger and freight trains and suburban traffic. The suburban traffic will be handled by multiple unit trains, each coach weighing 80 tons, and being patterned after the standard vestibule passenger coach. The passenger and freight traffic is handled by six locomotives; these locomotives are of the two four-wheel truck type, the two trucks being coupled together to the draft gear, leaving the body of the locomotive free from all stresses.

Pantograph collectors are used with overhead catenary suspension of the trolley wires.

Sir Robert Falconer

At the conclusion of the discussion on the above paper the members and delegates adjourned for dinner. Sir Robert Falconer spoke on the impressions he had gained on the occasion of his last visit to the western front a short time ago.

The bravery and fighting qualities of the Canadian Army Corps were never more in evidence than at the battle of Amiens, and later at Arras. Vimy Ridge was a glorious episode, and one in which the Canadians won lasting fame, but the two latter battles in the speaker's opinion were even more to their credit. Sir Robert had the good fortune to be present during the opening stages of the battle of Arras, and the sight of the Canadian reserve divisions pouring up to take their part in the struggle was one never to be forgotten; the columns of men, artillery and transport, moving on with clock-like regularity, and proving irresistible in battle to the foe.

The German troops opposite Arras got the surprise of their lives when they found the Canadians were the ones who were putting them to rout and bagging them as prisoners. It seems that these selfsame prisoners had been moved to the quiet Arras sector to rest up a bit after the terrific mauling they had received at Amiens a few days before at the hands of the Canadians.

One of the most important lessons the war could teach the people of the allied countries was the value of research and science in either war or peace. Organization was always one of Germany's strong points, and it was well known that the United States was her equal, but Great Britain was thought to be woefully backward in this particular. However, her organizing powers were not dead but merely quiescent.

Science, while adding horrors to the war as conducted by Germany, yet had achieved one of the miracles of the age in the success which had attended the efforts of the medical staff of the armies in the field. Preventive medicine and surgery had made greater strides in the last few years than ten years of peace would have brought about.

Engineering at the front was, in the last analysis, one of the material factors in the bringing of victory to the allied standard.

Long Span Transmission Lines

The evening session, held in the Chemistry and Mining Building, University of Toronto, was devoted to a paper read by Mr. S. Svenningson on the longest span river crossing yet erected. The paper dealt with some remarkable contruction work recently completed by the Shawinigan Water and Power Co. near Three Rivers, Que. The St. Lawrence River is crossed by transmission line wires on a span of 4,800 feet. Due to the necessity of maintaining navigation clearance, the towers are 350 feet high.

Four reinforced concrete cassions, 11 feet diameter for each tower, have been sunk to a depth of 45 feet and placed on the corners of a 60 ft. square. These piers are connected by heavily reinforced concrete beams 4 ft. wide by 8 ft. deep. There are two towers 350 ft. high, and 60 ft. square at the base, the upstream and downstream faces tapering to a width of 14 ft. at the top. The cross arm at the top is 14 ft. wide by 100 ft. long, and carries the three sheaves over which the main steel messenger cables pass to the anchor towers.

Three lines of cable 50 ft. apart span the river between the two towers. The cables are 1⅝ in. in diameter, and are

Bathed in Lubricant And Wound Spirally

That's "John Crane"

After "John Crane" is made into the bars shown below it is carefully cut into lengths and made into rings of required size. "John Crane" is nice, soft, flexible and compressible. It is more flexible than fibre packing. You can cut it with a knife, like fibre. It accommodates itself to conditions better. It fits any stuffing box. Can be made 1/16 larger or smaller with ease. Never dries out, becomes hard or brittle. You can keep it in storage indefinitely. 100% metal. Unaffected by temperature or pressure. Being made of babbitt, the friction is very small and the rods cannot be scored. Rods become highly polished and more frictionless with age. Seven years' constant service is common practice.

"JOHN CRANE" Soft, Flexible Metallic Packing

You see, Mr. Packing User, this is nothing like the shredded, twisted, shot, pressed in paraffin, braided and segmental types of metallic packing. It is entirely different and FAR SUPERIOR. It is mechanically correct and ideally suited to all kinds of packing problems in the power plant on piston rods, valve stems, Corliss valve stem, expansion joints, condenser tubes, evaporator tubes, boiler feed pumps, header valves, all kinds of high pressure hydraulic machinery, steam traps, throttle valves, etc.

You can use it without hesitation on any service such as steam, fresh or salt water, ammonia, oil, acids and corrosive gases, distillates, etc. In other words, you can use "John Crane" on ANYTHING, ANYWHERE pertaining to packing.

"John Crane" is made in coil form for valve stems, small rods, etc. No matter what thickness of packing you want, 1-32 in., 2 in. or more, we can furnish it. Try "John Crane" just once and you will make it your standard packing.

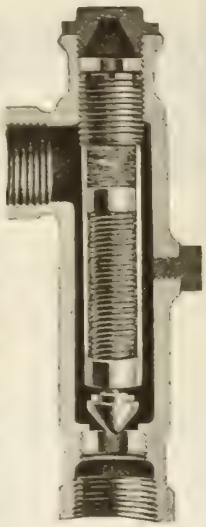
COAL IS SCARCE!
INDIVIDUAL TRAPPING SAVES IT.

The old-fashioned method of carrying live steam with condensation through long lines of piping to a heavy, cumbersome bucket or float trap wastes a large amount of steam, because the useless radiation resulting therefrom necessitates greater coaling at the boiler in order to keep up the desired steam pressure.



STEAM TRAP
SARCO

will stop this waste of coal because you can install five Sarcos on your lines for the price of a single bucket or float trap, thereby releasing the condensation at every advantageous location and keeping the line free and clear at all times.

Let us send you one on 30 days' free trial.

made of galvanized plough steel. They are composed of six strands of 19 wires each and a stranded core of 30 wires. To each end of the center span cables is yoked two anchor span cables; these are carried over the tower on the 8 ft. diameter sheaves and then down to a point about 20 ft. from the anchors. At this point equalizing beams are cut in the lines, and the load is transmitted from this point to the anchor piers by means of short straps of 1¾ in. cable.

It was originally intended to use the main cables as conductors and to insulate them from the tower by specially-designed insulators. Unfortunately these insulators were not completed in time for erection and the main cables are now used as messengers carrying a No. 1/0 stranded copper conductor on suspension insulators.

Visit Local Plants

Saturday morning the delegates and local members visited the British Forgings, Leaside Munitions, and the Strachan Ave. terminal station of the Ontario Hydro Electric Power Commission and their laboratories on the same site. Canada's share in the supplying of munitions to the Allies and to the United States is due in no small measure to the enormous output of the British Forgings and Leaside Munitions plants, and the opportunity of visiting the world's largest electric steel plant was one which the majority of the delegates availed themselves.

CATALOGUES

The Swedish Gage Co., Incorporated, have recently issued a new catalog, describing in a very comprehensive manner the complete line of Johansson gaging tools. The book is 8 x 10 inches, 44 pages, and is printed on high-grade calendered stock. It is profusely illustrated, the various views showing the manner in which the blocks should be placed together, and examples for determining the selection of blocks for different combinations. The section on new accessories and the typical applications are interesting and instructive features of the book. Separate sections are devoted to the description of Johansson adjustable snap and tolerance gages, illustrating in a clear manner the method in which they are set and checked. H. E. Streeter, 10 Cathcart St., Montreal, is the Canadian representative.

In Catalogue No. 17, Butterfield and Company have listed their numerous lines of taps, dies, screw plates, and reamers. Arbors, countersinks, dies, die holders, guides, screw plates and screw plate stocks are shown for the various standard threads in common use both in the English and metric sizes. The line of reamers shown is unusually complete, and includes both English and metric. A set of tables containing useful information about screw threads, is found at the back of the book.

Sentinel Steam Stop Valves, Check Valves, and Accessories," is the title of a book recently published by Alley and MacLellan, Ltd., Glasgow, dealing with plant apparatus manufactured by them. The stop valve is noted for the slight loss of pressure caused by its presence in the steam line, as the passages are practically full area and the flow of steam being directed in easy curves the loss of pressure is negligible The chests are of best Scotch iron, and the section at the flanges is rounded to eliminate crystallization at the sharp corners. Chamfering the seats combined with the shape of the internal valve throws the steam clear of the valve seats. Feed piping arrangements are shown. The Fullway valve described is a valve especially designed for high steam pressure, and the interior wedging action of the spindle connection eliminates wear due to the opening of closing of the valve and at the same time assures a steam-tight joint when closed. Valve arrangements, steam traps, and other auxiliary apparatus are also shown.

System in Trucking is the title of a recent booklet published by the Stuebing Truck Co., Cincinnati, Ohio. The advantages of a thorough system of trucking in the reducing of costs is well brought out. The adaptability of the trucking system to various uses such as trucking in the foundry, handling breakable products, handling high loads, such as timber, express companies, automobile firms, etc., is well shown. Complete drawings and illustrations show the rugged and simple design of the trucks and show the hydraulic double acting safety check. The lifting and the steering lever is of steel, and the single control is also of steel. The axles are of high carbon steel, and are provided with Hyatt roller bearings. Special trucks are also featured, the design and construction of these trucks permitting the building of specials at very little expense. Trucks can be lengthened by using longer side rails, and made wider by increasing the length of the rear axle and extending the wings. Standard and special platform applications are shown by a series of drawings, which include many of the various types in commercial use for various manufacturing purposes.

Going Up.—The Canadian Aero Company, composed of well known St. John, N.B., capitalists, has applied for a Dominion charter. The company will have a capital of $2,500,000 to begin with. They propose to conduct an aerial mail service between Halifax, Boston, Montreal and New York, and claim that on a rate of 8 cents per oz. they can make a good profit. Later on they will consider taking passengers.

New Fire Engine for Trenton, N.S.—The new fire engine, built to order for the town by the American LaFrance Fire Engine Co., Toronto, arrived in Trenton recently. Mr. Gales Coleman had gone to Toronto to pilot the engine, which was brought to the Trenton garage.

Farnsworth Condensation Pumps

The coal shortage, in so far as it has called our attention to wasted heat, has been a blessing in disguise.

Thousands of tons of coal may be saved by Farnsworth Condensation Pumps. They offer a double saving. First, by using a closed system keeping the condensate under pressure they return the maximum number of heat units to the boiler. Secondly, they can be operated on a small fraction of the steam required to operate a reciprocating pump.

Farnsworth Condensation Pumps are replacing other types of pumps and steam traps in a great many places. Let us tell you what they are doing in large Canadian Plants.

METLSKIN does prevent scale

Send for this illustrated booklet. It explains the dose, the method of action, and other important details

Some of Canada's and the United States' biggest and most representative plants have learned the truth of the above statement from first-hand experience.

So many "compounds" and "cure-alls" have been foisted upon unwary power-plant owners that the feeling, common to many of them, is one of doubt, of skepticism. And small wonder!

METLSKIN is not a "compound," nor does it work on the same principle. It is a boiler metal treatment, a boiler preservative that gradually removes scale by a safe process. When the scale has been entirely removed METLSKIN forms a minute, grayish-white skin or covering over the bare metal.

So long as the daily dose is continued the scale-forming particles in the feed-water cannot adhere to the metal. Nor will METLSKIN work injury to any part of the boiler or system. That is one of the strongest features of the GUARANTEE BOND.

METLSKIN cannot contaminate the steam. It may be used safely in any plant where live steam comes in contact with the manufactured product.

If you are a skeptic, a doubter, ask for the booklet, GUARANTEE BOND, prices, etc. You will be interested, we know.

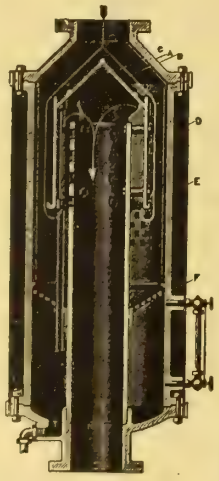
ADVERTISING to be successful does not necessarily have to produce a basketful of inquiries every day.

The best advertising is the kind that leaves an indelible, ineffaceable impression of the goods advertised on the minds of the greatest possible number of probable buyers, present and future.

III IMPORTANT THINGS
TO CONSIDER ABOUT A SEPARATOR.



I. **THE PLAN**—Is it sensible, will it work, no matter how large the Separator or how well made?

II. **THE SIZE**—Is it big enough regardless of plan, will it hold a good dose of water?

III. **THE CONSTRUCTION**—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

GRATON & KNIGHT

Standardized Series
LEATHER BELTING

Tanned by us for belting use

GRATON AND KNIGHT

When the Belt Works Right

One ounce of performance is worth a ton of speculation as to horse-power delivery. The best answer in belt performance is when the belt works right—with the utmost of uninterrupted driving energy; with economy written into every fuel bill.

Each Graton & Knight Standardized Leather Belt is tanned and built for some specific power purpose. This is where the Graton & Knight standardization idea comes in—belting standardized for every drive.

It may be that you are using an unnecessarily good belt on a certain drive and one not good enough on another. Select a drive in your plant and let us recommend the proper Standardized Belt to use—then watch the results. When the belt shows you that it is working right, that it is giving all service possible, you will be ready to discuss the matter of applying Graton & Knight Standardization further.

If you have kept suitable records, you know just where the belt losses are in your plant. If not, you are only guessing. Start a belt record. Write us for the necessary cards. Tell us the number of drives in your plant and we will mail record cards without charge. Write also for a copy of our booklet, "Standardized Leather Belting" explaining scientifically the application of standardization to belting.

CANADA'S DEPARTMENTAL HOUSE FOR MECHANICAL GOODS

You'll Not Need So Much Coal!

You can't afford to waste coal by inefficient methods of heating your water supply in these days of fuel shortage and high prices. Both fuel and repair expense can be saved by installing

ALBERGER MULTI HEAD HEATERS

They save coal by the rapid heat transfer between the steam and the water. Less steam is required because of their efficient multi-pass design made up of four or more groups of helically corrugated copper tubes. The divided floating head compensates for the unequal expansion of the tubes due to the temperature difference between the water as it enters and leaves the heater.

The internal troubles are removed and all the usual troubles, such as leaks, split tubes, cracked heads, etc., disappear.

The tube corrugations also cause the water to take on a whirling, scouring action which lessens the tendency to scale.

Both the operating and upkeep expense is therefore small.

Alberger Heaters are furnished in capacities from 200 to 200,000 gallons per hour. Let us send you complete data.

How to Measure Transmission Losses

ELECTRICALLY EQUIPPED PLANT

First Throw the belt off the motor-driven shaft to test and take proper reading for input to drive motor only.

Second: Put the belt back on the motor pulley and shift all belts on the main line to the idler pulleys on the counters. Take power reading. The difference between these two readings will show the net line shaft transmission loss.

STEAM PLANT

First: Ease the belt off the fly wheel or pulley of the engine, indicate the engine.

Second: Put the main driving belt back and run line shafting at normal speed with all belts driving loose pulleys only, indicate the engine. The difference between the indicated readings with the main belt off and on will show the net line shaft transmission loss.

It will then be a simple matter to figure out by dollars and cents the amount wasted annually in the friction loss of plain bearings, and it will be easy to determine if it is worth while to save 50% of this waste by the application of S K F Ball Bearing Hangers or Rigid Pillow Blocks.

The MacLean Business & Class Publications in Canada

TO SELL or buy from Canada such lines as machinery, hardware, food products, dry goods, books and stationery, paper, printing machinery and supplies and general merchandise of almost every description, raw or manufactured, use or consult the MacLean Business and Class Publications, as per list below. For special information, write the publishers. Concerning the quality of the MacLean publications, let this copy of POWER HOUSE which you hold in your hands speak for all. The MacLean list of 14 publications is as follows:—

The Canadian Grocer (Est. 1886)
Serving the Grocery, Provision and Foodstuffs Trades. Published weekly.

Hardware and Metal (Est. 1889)
Serving the Hardware, Stove and Metal-working Trades. Published weekly.

Dry Goods Review (Est. 1889)
Serving the Dry Goods Trade generally; Wholesale, Retail, Manufacturing and Department Stores. Published monthly.

Men's Wear Review (Est. 1898)
Serving the Manufacturers of Clothing, Underwear, Shirts, Collars, Neckwear, Footwear, Hats and Caps and Allied Sundries, and their Retail Distributors. Published monthly.

Canadian Machinery (Est. 1905)
Serving the Machinery, Metal-working, Iron and Steel, Foundry and Allied Trades. Published weekly.

The Power House (Est. 1907)
Serving the Operating and Consulting Engineers and Power Superintendents, Devoted to the Generation, Transmission and Application of Steam, Gas, Electric, Air and Water Power; and to the operation of Refrigerating Machinery. Published monthly.

Bookseller and Stationer (Est. 1884)
Serving the Book, Stationery, Fancy Goods and Associated Trades. Published monthly.

The Sanitary Engineer (Est. 1907)
Serving the Manufacturers of Sanitary, Heating and Ventilating Machinery, Systems and Equipments, and those installing them. Published semi-monthly.

Marine Engineering of Canada (Est. 1910)
Serving the Marine Engineering, Merchant and Shipbuilding Trades. Published monthly.

Canadian Foundryman (Est. 1909)
Serving Foundries and the Pattern-making, Plating and Polishing Trades. Published monthly.

Printer and Publisher (Est. 1892)
Serving the Publishing, Printing, Paper-making and Allied Trades. Published monthly.

The Financial Post (Est. 1907)
Serving the Business, Investment and Financial Interests of Canada. Published weekly.

MacLean's Magazine (Est. 1896)
A popular family and literary magazine; the most important in its field in Canada. Published monthly.

The Farmers' Magazine (Est. 1910)
Serving the agricultural and rural communities of Canada. The only farm and country life publication in Canada having extensive national circulation. Published semi-monthly.

This fact may interest you: namely, the MacLean organization is the largest concern of its kind in the British Empire. The output of its mechanical department every working day is the equivalent of a 125-page publication of the size and type of this copy of *Power House.*

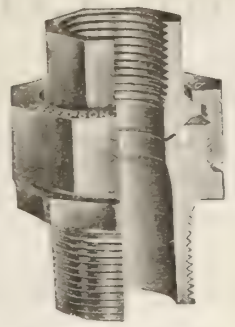
"Look for the Name on the Nut"

Buy Thrift Unions—



"Look for the Name on the Nut"

JEFFERSON UNIONS

THRIFT—our national watchword—must be practiced on every opportunity and from every angle. It is of utmost importance that waste of labor and materials be eliminated. JEFFERSON UNIONS are Thrift Unions because they conserve labor and materials. "Just-as-good" unions require almost as much material as "JEFFERSONS," shipping and installation costs are equal—but when the defective union breaks down, there is the added expense for repairs.

"SAFETY FIRST"—Insist on getting dependable unions. It's too late to investigate when superheated steam sizzles out of the "just-as-good" connection. The best sounding promise is valueless after the damage is done.

Your jobber has "JEFFERSONS" in stock that will meet practically every condition about the mine. Just look them over and you'll see why it's always safer to "look for the name on the nut." Write to-day for our Catalog, "UNIONS," which shows every JEFFERSON style and type.

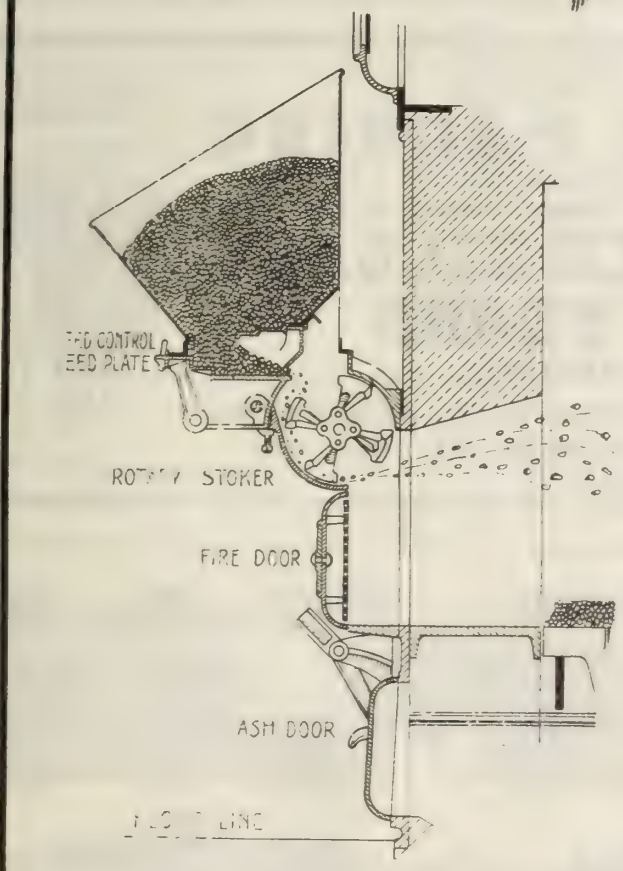
Galt Sprinkler Stoker

See the Sprinkler in action! Note how logically it operates!



Cut Your Coal Bill 10 to 20%

YOU can declare dividend of 10 to 20% on your coal investment every day, week, month and year that the GALT SPRINKLER STOKER is installed in your plant. This is a fact that is being proven every day by many of Canada's most prominent firms. Some of them include:

R. Forbes Co., Ltd., Hespeler, Ont.—First order, 6 Stokers; second order, 10 Stokers.

Municipal Hospital, Winnipeg, Man.—First order, 2 Stokers; second order, 5 Stokers.

Hudson Bay Co., Vancouver, 4 Stokers.

Parliament Buildings, Edmonton, 6 Stokers.

Royal Bank Building, Toronto, 4 Stokers.

Reports from leading reliable firms confirm the facts that GALT SPRINKLER STOKERS—

1. **Effect a saving in coal from 10% to 20%.**
2. **Effect a saving in labor from 25% to 50%.**
3. **Give a brilliant, thin, perfectly level fire.**
4. **Give smokeless combustion.**
5. **Increase the boiler capacity.**
6. **Increase the percentage of the CO$_2$.**
7. **Burn the fuel completely to the finest ash.**
8. **Operate for years without need of repairs.**

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction.* Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satistactory operation, but practically *eliminates expensive shut-downs.* Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

Very Popular with Shipbuilders

USES

This valve is for use on exacting installations. It will make any desired reduction and will maintain a constant delivery pressure regardless of fluctuations of the initial pressure.

CONSTRUCTION OF STOCK REGULATORS

All valves have iron bodies, bronze stem and stuffing box, phosphor bronze diaphragms, seats of composition suitable for the required service; iron diaphragm chamber and steel springs. The main valve is controlled entirely by the small auxiliary valve. This auxiliary valve closes and opens the main valve by admitting initial pressure to, and releasing it from, the diaphragm chamber of the main valve according to the demand of the delivery side. Regulators of this description are suited for pressures up to 150 pounds, and will be furnished at above prices. When regulators are required for pressures in excess of 150 pounds we will furnish suitable material. Prices upon application.

STRAINER

In all cases it is advisable to use a strainer to prevent obstruction from grit, scale, cuttings, etc. Blow out pipes thoroughly before installing valve.

INFORMATION IN ORDERING

In ordering give highest and lowest initial pressure and required low or delivery pressure, approximate quantity or volume to be used per minute, size of high pressure pipe and low pressure pipe.

In ordering flanged end valves give diameter of flanges and bolt circles and the number and size of bolts.

INSTALLATION

Note.—Any proper working regulator acts as a check valve. Where the building up of the pressure is to be avoided use our diaphragm operated relief valve E5060.

We will not be responsible for improper selection of valves.
Consult us regarding the best type for your service.

Defender CO_2 Case

A permanent equipment for the Boiler Room to mount either Single or Three Chamber Gas Analysers in and the gas lines from the different boilers can be run into the case. The Defender Gas Suction Pump is mounted on the outside of the case at the right. The spring shelf is for holding the water bottle up to the gas line. A few draws of the gas pump will draw the gas from any boiler into the analyser; in this manner a reading for CO_2 can be taken in less than one minute's time.

No Orsat is complete for a boiler room that is not permanently installed in a case and with gas pump.

A Little Device With a Big Job Ahead of It

The Dominion must get more **useful** heat out of its coal; that fact is more obvious than either the **cause** of coal-waste or the **remedy** for it.

Those who know the possibilities for coal-waste in steam-heating systems—and those who ask for authoritative advice on the subject—realize that radiators choked with air and water are guilty in the highest degree.

The Dunham Radiator Trap **can** stop this waste of coal —**is** stopping it in homes, office buildings and factories everywhere—and **will** stop it for you.

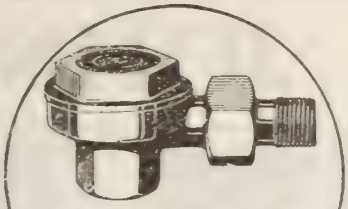
The DUNHAM HEATING SERVICE

We believe in FACTS and will gladly present them to you in a most convincing manner

C. A. DUNHAM CO., LIMITED

TORONTO - ONTARIO

Hamilton Montreal Ottawa Winnipeg
Vancouver Calgary

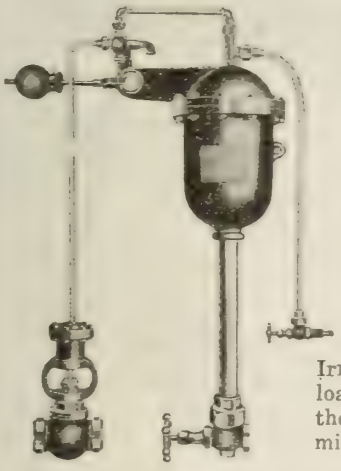


DUNHAM
Radiator Trap

It is screwed into the bottom of the radiator, requires no attention, makes no noise, cannot leak steam or water. By permitting the steam to fill the entire radiator it gets more *useful* heat from the coal. Can be applied also to existing steam heating systems.

It comprises a body, a cover and a thermostatic disc which is secured in the cover. There are no loose parts—no sliding contacts—nothing to gum up —nothing to obstruct the valve opening. It is made with special roughing-in measurements for the replacing of imitating devices.

VIGILANT Feed Water Regulator



Is it worth your while to take chances when a few dollars would install the Vigilant, and with it on the job you would know you were fully protected from high and low water accidents?

Irrespective of firing or load variations, it keeps the water within ¼" of middle gauge.

And it positively cannot get out of order. Has no float or other unreliable part.
Moreover, this Vigilant Feed Water Regulator will lower your fuel consumption 3 to 17%.

Write for Catalog.

The Chaplin-Fulton Manufacturing Campany

28 Penn Avenue - Pittsburgh, Pa.

DAVIS PRESSURE REGULATORS

One of the Davis Steam Savers

can be depended on to maintain an even, steady steam pressure —regardless of fluctuations in the load or in the boiler pressure.

Davis Pressure Regulators are steam savers as well as trouble savers. They automatically reduce any pressure—steam, air or water—to any desired lower pressure. Steady, sturdy reducing valves that can be relied on at all times and under all conditions. Positive in action—no diaphragms, no springs, no delicate parts.

Write the G. M. Davis Regulator Co., 434 Milwaukee Ave., Chicago, for the new Davis Catalog of steam savers. Branches in principal cities

DAVIS VALVE SPECIALTIES
STEAM SAVERS SINCE 1875

JOHNS-MANVILLE

MASTIC FLOORING—For the over-worked floor in the war-time plant

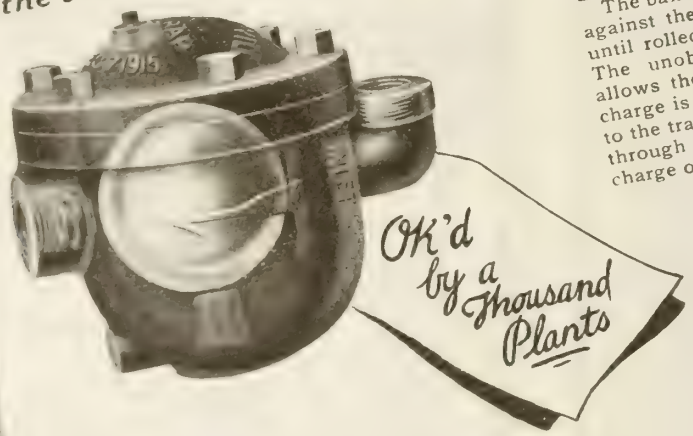
Under conditions where hard usage and accidents make occasional repairs necessary—Johns-Manville Mastic Flooring offers another advantage and again proves its superiority.

Mastic Flooring is easily repaired. Just cut out the worn or damaged section. Reheat this same material with a small amount of flux which we furnish, then relay. The new spot—floated and rubbed down to the proper level—is immediately one piece with, and has all the characteristic qualities of the surrounding floor.

Johns-Manville Mastic Flooring is unequalled even under the heaviest trucking conditions. It is waterproof and is unaffected by alkali, brine and ordinary acid solutions. It is noiseless in character and of a peculiar holding quality which tends to prevent slipping.

Extremely tough and durable, under ordinary service Johns-Manville Mastic is practically wear-proof and under abnormally severe usage its maintenance cost is a minimum.

Its simplicity is its life insurance the Johns-Manville Steam Trap



WHEN you use Johns-Manville Steam Traps you don't have to figure depreciation, because it is practically nil. And the same simplicity of construction which insures it against wear makes the Johns-Manville Trap positive in operation. There's nothing to get out of order and nothing to adjust.

The ball is the only moving part. It is held against the outlet orifice by steam pressure until rolled up by water rising in the trap. The unobstructed orifice—now exposed—allows the water to discharge and the discharge is continuous as long as water flows to the trap. If air is present, it is drawn out through the vortices that form at the discharge orifice.

Johns-Manville Steam Traps are made in various sizes for all commercial pressures. Ask our nearest branch to send you the Steam Trap Bulletin.

If any advertisement interests you, tear it out now and place with letters to be answered.

Becoming a Bigger Man

WHAT is the difference between some men you know and others known to you? Why are some men earning $3,000 a year and some $30,000? You can't put it down to heredity or better early opportunities, or even better education. What, then, is the explanation of the stagnation of some men and the elevation and progress of others?

We are reminded of a story. A railroad man, born in Canada, was revisiting his home town on the St. Lawrence River. He wandered up to a group of old-timers who sat in the sun basking in blissful idleness. "Charlie," said one of the old men, "they tell me you are getting $20,000 a year," "Something like that," said Charlie. "Well, all I've got to say, Charlie, is that you're not worth it."

A salary of $20,000 a year to these do-nothing men was incredible. Not one of the group had ever made as much as $2,000 a year, and each man in the company felt that he was a mighty good man.

Charlie had left the old home town when he was a lad. He had got into the mill of bigger things. He developed to be a good man, a better man, the best man for certain work. His specialized education, joined to his own energy and labor sent him up, up, up. To put it in another way: Charlie had always more to sell, and the world wanted his merchandise—brain, skill and ability. Having more to sell all the time, he got more pay all the time.

Charlie could have stayed in the old home town; could have stagnated like others; could have been content with common wages. In short, Charlie could have stayed with the common crowd at the foot of the ladder. But Charlie improved himself and pushed himself, and this type of man the Goddess of Fortune likes to take by the hand and lead onward and upward. Almost any man can climb higher if he really wants to try. None but himself will hold him back. As a matter of fact, the world applauds and helps those who try to climb the ladder that reaches towards the stars.

The bank manager in an obscure branch in a village can get out of that bank surely and swiftly, if he makes it clear to his superiors that he is ready for larger service and a larger sphere. The humble retailer can burst the walls of his small store, just as Timothy Eaton did, if he gets the right idea and follows it. It is not a matter of brain or education so much as of purpose joined to energy and labor. The salesman or manager or bookkeeper or secretary can lift himself to a higher plane of service and rewards if he prepares himself diligently for larger work and pay. The small manufacturer, the company director, the broker—all can become enlarged in the nature of their enterprise and in the amount of their income—by resolutely setting themselves about the task of growing to be bigger-minded men.

Specialized information is the great idea. This is what the world pays handsomely for. And to acquire specialized information is really a simple matter, calling for the purposeful and faithful use of time. This chiefly.

One does not have to stop his ordinary work, or go to a university, or to any school. One can acquire the specialized information in the margin of time which is his own—in the after-hours of business. Which means: If a man will read the right kind of books or publications, and make himself a serious student at home, in his hours—the evening hours or the early morning hours—he can climb to heights of position and pay that will dazzle the inert comrades of his youth or day's work.

IF business—BUSINESS—is your chosen field of work, we counsel you to read each week THE FINANCIAL POST. It will stimulate you mentally. It will challenge you to further studious effort. It will give you glimpses into the world of endeavor occupied by the captains of industry and finance. With the guidance of the POST, and with its wealth of specialized information, you, a purposeful man, aiming to go higher in life and pay, will find yourself becoming enlarged in knowledge and ambition, and will be acquiring the bases and facts of knowledge which become the rungs of the ladder you climb by.

It is the first step which costs. But this cost is trivial—a single dollar. We offer you the POST for four months for a dollar. Surely it is worth a dollar to discover how right we are in our argument. If yoou have the will to go higher in position and pay, sign the coupon below.

THE MACLEAN PUBLISHING COMPANY, LIMITED,
—143-153 University Avenue, Toronto.

Send me THE FINANCIAL POST for four months for one dollar.

Why Laco Lamps Give More Light

Laco Bulbs are scientifically correct in shape
The Laco Vacuum is mechanically exhausted and sealed
Laco Filaments are made of higher-grade tungsten
Laco Filaments are mounted to give best distribution of light
Laco Filaments are mounted to best withstand rough usage
Laco Lamps are made complete in one factory and perfected in every stage

LACO NITRO LAMPS

are filled with rare, inert gases, including ARGON—the rarest and most efficient gas. Argon is almost unobtainable by other manufacturers, but is made in the LACO factories.

Laco Lamps are Guaranteed to Give the Candle-Power that U.S. Standard Specifications Provide

Our Lighting Engineers are at your service. Discuss your lighting problems with us to-day.

"Bulb-Blackening," Current-Consumption, Breakage Danger
are reduced to a minimum in Laco Lamps

The result is :
BRIGHTER--CHEAPER--LONGER LIFE

Laco Lamps are Guaranteed for 1500 Hours Useful Life

No other lamp promises more than 1000 hours, and very few average 60 % of this.

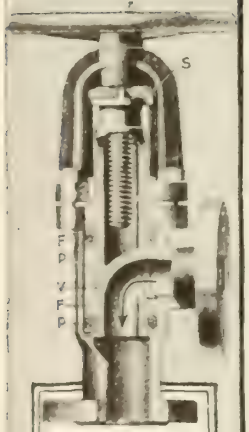
Where Electric Power is Made

Municipal lighting companies take no chances when buying equipment. As current must be supplied uninterruptedly, every precaution is taken against shut-downs.

Take corporations such as

Montreal Light, Heat & Power Co., using 24.
Cleveland Elec. Ill'g. Co., using 178.
Edison Elec. Ill'g. Co., Brooklyn, using 100.
Potomac Elec. Lgt. & Pr. Co., Washington, D.C., using 24.
Duquesne Lgt. Co., Pittsburgh, using 34.
Omaha Elec. Lgt. & Pr. Co., using 97.
Worcester Elec. Lgt. Co., Worcester, Mass., using 36.

Each has its boilers equipped with from 24 to 178 YARWAY (formerly Simplex) "Seatless" Blow-off Valves—a choice that in effect, becomes a recommendation of the very highest character.
In the YARWAY (formerly Simplex) there are no seats or discs to cut, clog or grind down. There are no pockets to gather sediment—no obstructions of any kind. The port is free and wide open. Packing is protected and will last for years.
Other good points may be learned by trying a YARWAY for 60 days. It may be returned if not satisfactory.
Write for one to-day, stating size of line and whether screw or flange, angle or straightway.



Operation:
In closing valve, shoulder "S" on plunger "V" engages the loose follower gland "F," compressing packing "P" above and below the port, making an absolutely tight valve.

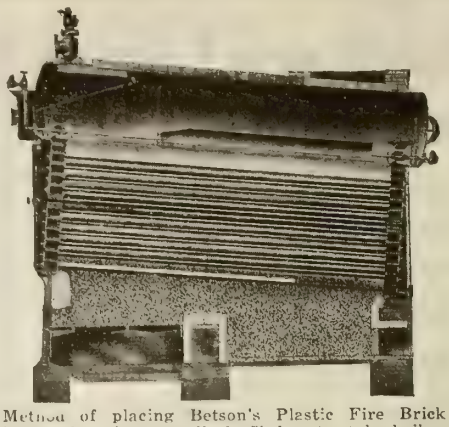
SIMPLEX



Method of placing Betson's Plastic Fire Brick Baffles in a horizontally baffled water-tube boiler.

Baffles in Your Boilers?

Where are they, and what is their condition?
Do you ever look at them?
This is no idle question—more coal is being wasted by defective baffles in water tube boilers than in almost any other way. If the baffles have cracked, or slid out of place, or have been forced apart or crushed by the movement of the tubes, the furnace gases are allowed to short circuit, passing to the chimney at a high temperature.

Betson's Plastic Fire Brick Baffles as installed in a cross-baffle water-tube boiler.

The old idea that a square foot or heating surface in one boiler is just as good as a square foot in another is giving way to the more scientific notion that a great deal depends upon the gas circulation. The volume of the gases contracts about 50% due to the reduction of temperature in passing through the boiler, and many engineers are now proportioning gas passages so that a uniform velocity is maintained throughout. This implies tapering passages and sloping baffles, which are difficult to form with separate fire-brick baffle blocks, but are easily secured by the use of Betson's Plastic Fire Brick.

BETSON'S

REG. U.S. TRADE MARK PAT. OFF. PLASTIC FIRE BRICK

is the universal boiler lining material. It is placed in a moist, plastic condition, as received, compacted by pounding and vitrified by four or five hours' slow firing, after which the boiler can be put at once into full service. Betson's Plastic Fire Brick consolidates into a one-piece, gas-tight, jointless, leakless structure which does not fail by the cracking, spalling, disintegration of the fire brick mortar, and is not subject to the many other ills which attack separate block or brick linings or baffles.
Betson's Plastic Fire Brick is no mystery and no experiment. It consists of high-grade refractories, prepared by a special mechanical process which eliminates expansion and contraction. It has been in use for years in many large boiler plants. Order a barrel for emergency repairs, and by plugging up the holes you will be able to keep old block or brick linings in service for weeks, perhaps months, until you can shut down and reline completely with Betson's.
With Betson's there is no waiting, as for specially shaped blocks, nor for an expert mason. Your own men can do the work.

Ask for Catalogue "R"

"Good Morning, Jim."

"Good morning, Mr. Hawley."

The new Superintendent had stopped in the engine room, where Jim, the Engineer, was getting everything ready for a flying start. The company had a big Government contract, and was running twenty-four hours a day, six days a week, three shifts and five engines, four of which were running.

"What are you doing with No. 5, Jim?" asked Mr. Hawley. "Got some belt trouble?"

"No, sir. While she's shut down I've had George paint the back of that new belt."

"Paint it?"

"Yes, sir, with CLING-SURFACE. You see, all belts get pretty dry, and it used to bother me a lot until I got this CLING-SURFACE. Well, the company advises painting the back of a good clean belt with CLING-SURFACE, so it will soak it up quicker and prevent cracking, and I gave it a trial. That's the new belt—all the others were painted about a year ago."

"How do they work?"

"Fine! There's the belt on No. 1. I had that painted last year, when Mr. Hodges was Superintendent, and put the CLING-SURFACE on just warm enough to use. You'd be surprised how quick the stuff got into the leather, and since then it's just as clean and pliable as a kid glove."

"Do they slip?"

"Not a bit. George puts a little CLING-SURFACE on the belt face with a stick about once or twice a week—just as fast as they will take it up, and the belts always pick up the load and hold it. And I haven't had to take-up any one of them since this treatment was started a year ago."

* * *

It is a patriotic duty to conserve your present equipment. Instead of buying new belts, treat your present drives with CLING-SURFACE, and make them last longer and work better for you.

Prove it at our expense. Order a 25 or 50-pound can on trial—60 days, and with these results guaranteed **before** you pay.

Remember, use CLING-SURFACE and you won't need belt dressings.

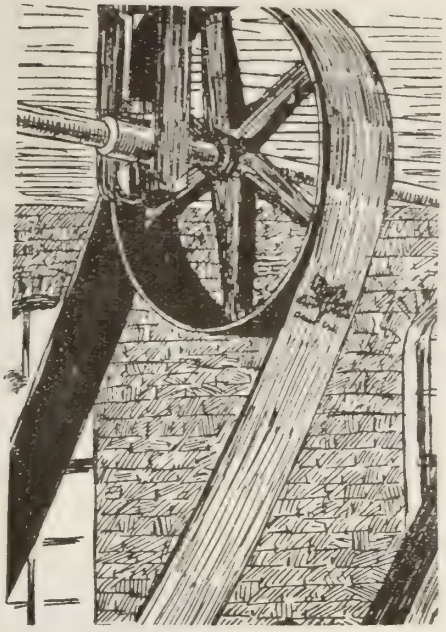
Mr. Chief Engineer—

Be able to say

"It's Working FINE"

when the Superintendent asks about the new belt you got your plant to buy.

Be sure to spccify



D. K. McLAREN'S

Genuine British Oak-Tanned

LEATHER BELTING

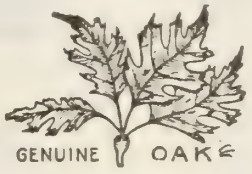
when putting in your requisition for a new belt. And you'll ensure a long, trouble-free, efficient service.

Think what being able to say "It's working fine," will mean to you instead of having to report trouble every little while, as is the case in many places where precaution is not exercised in the purchase of belting.

D. K. McLaren's Leather Belting is made exclusively from close-trimmed butts of the finest selected hides, tanned by the old-fashioned but the proven most effective British Oak Tanning Process.

It doesn't require the attention and expense that is common where ordinary belting is used, because there is practically no slip, and it seldom requires tightening.

Many of the largest Canadian Plants are our steady customers. If you wish to ask them how they like this belting, we will be glad to send you their names and addresses.



REGISTERED TRADE-MARK

This trade-mark guarantee is on every piece of D. K. McLaren's Leather Belting. Look for it.

NOTICE

TO

Stationary and Hoisting Engineers

Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

HON. F. G. MACDIARMID, Minister of Public Works and Highways. W. C. McGHIE, Chairman of Board.

W. A. RIDDELL, M. A. PH. D., Superintendent, Trades & Labour Branch.

NATIONAL BOILER GIRTH SEAM PROTECTORS

If your Boiler is not fire-cracked it eventually will; prevent this by putting on a National Boiler Protector. You will save cost in repairs and prolong life of the boiler. All new boilers should be protected.

Write Us for Particulars.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID,
Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D.,
Supt. Trades & Labour Branch

D. M. MEDCALF,
Chief Inspector of Steam Boilers.

ELECTRICAL SAFETY AND ECONOMY

ECONOMY
Renewable
FUSES

Cut Annual Fuse Maintenance Cost 80%

Economy "Drop Out" Renewal Links are responsible for this saving.

A "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.

A sustained arc is impossible.

It's the work of a moment for even a novice to replace the link and renew the fuse.

First in its field—first in efficiency.

Order from your dealer.

Write for Catalogue 24.

Economy Fuse & Mfg. Co.

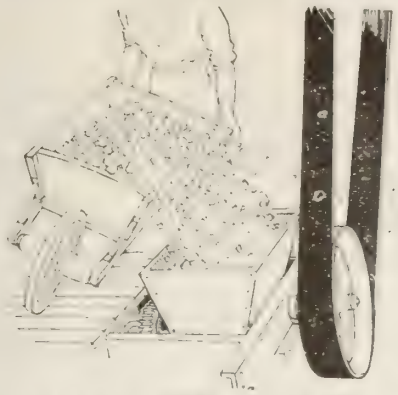
Manufacturers in Canada of S.& C.High Potential Fuses--to 150,000 volts.



SCANDINAVIA BELTING

Is a Good Belt for Dusty Places

In cement plants and brick plants where there is lots of dust, this belt is producing results that are very satisfactory for the mill operators.

You know how wearing grit is on a belt, and you want a belt that will not come apart when only partly worn through.

"Scandinavia" is this kind of a belt—there are no plies to come apart—it is solid woven. We have seen these belts still giving good service when the thickness was half worn through, and on the pulley side of the belt there were no frayed ends—the surface of the belt was smooth.

Mr. Plant Manager, you know what this means. If you require a belt for operating in a dusty place, let us ship you one, please. It will be a pleasure to us both.

FEDERAL ENGINEERING CO. Limited
172 John St., TORONTO

NOTE:—Do not use "bar" or "stick" belt dressing on textile belts.

Dispose of Condensation

as fast as it accumulates in Steam Coils, Jackets, Radiators, etc., without reducing pressure or permitting live steam to escape.

with The ANDERSON

Model "D" Steam Trap

This trap is fully guaranteed to give the economical and efficient service it is your right to expect. Absolute accuracy is assured, because all parts are machined to solid gauges.

Moreover, without unscrewing a single steam joint or pipe connection, you can change the valve and seat from high to low pressure or vice versa **in five minutes.** And a removable strainer prevents pieces of scale, packing, etc., from entering this Anderson Trap.

Ask for Descriptive Booklet.

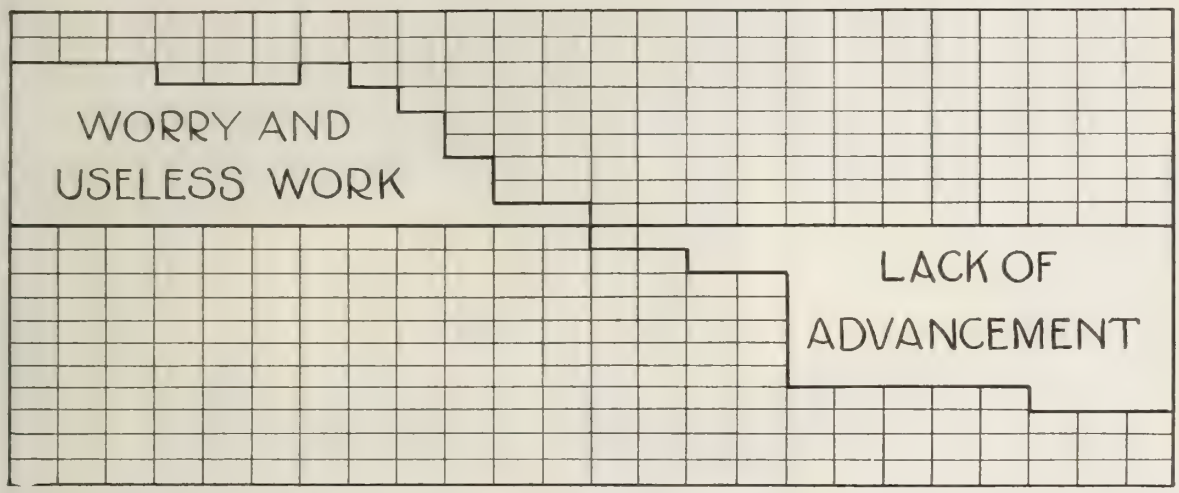
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary,

Gates Boiler Furnace

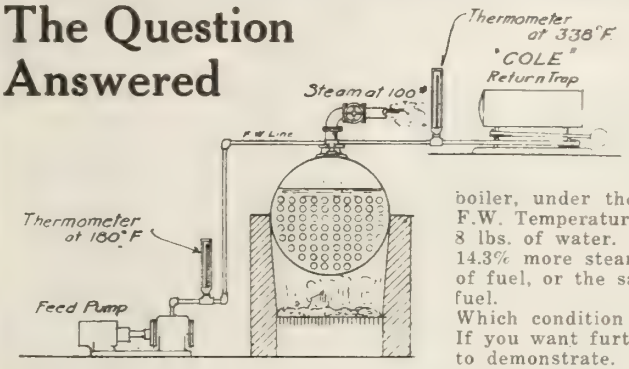
Patented 1916

Will last three times as long as ordinary good grade Fire Brick. These blocks are inter-locking, and made so that any handy man or fireman can renew them without disturbing any of the other brick work.

WRITE FOR PARTICULARS.

John W. Gates 2 St. James St., MONTR_A. E

The Question Answered



Our last advertisement propounded a question. If you haven't worked it out, here is the answer:

The boiler with feed water at 180° will evaporate say, 7 lbs. of water. The same boiler, under the same conditions with F.W. Temperature of 338° will evaporate 8 lbs. of water.

14.3% more steam for the same amount of fuel, or the same steam for 14% less fuel.

Which condition obtains in your plant? If you want further information, ask us to demonstrate.

GEO. W. COLE, Limited, 2002 Dundas Street W., TORONTO

Morehead Back to Boiler SYSTEM

Out of the 600,000,000 tons of coal mined in Canada and United States annually, about ten per cent. of it is needlessly wasted.

Unless you are delivering all the condensation back to your boilers, while it is HOT you are a contributor to this big waste. Coal is too scarce to let this waste continue. The **Morehead Back-to-the-Boiler System** will stop it. It delivers **hot** condensation back to the boiler as pure hot feed water, and thus saves valuable heat units.

The "Morehead System" works automatically, wastelessly, completely. It not only saves fuel it saves boilers and hard work too. Equally controlled temperature in your whole plant, freedom from the troubles of steam pumps, and many other advantages accrue from its use.

Adopt the "Morehead" and help stop a great national waste.

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CAT ALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.**

The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH

Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.

Nut with Nut-Guards

Inquiries from Importers and Dealers Solicited. Send for Catalogue No. 55.

INGLIS BOILERS

Inglis quality has not been attained in a day or a month or a year or two. It represents the fruit of over half a century in meeting the requirements of boiler users.

Inglis boilers are Canadian standard in materials, workmanship and efficiency. They ensure a lifetime service with a minimum of repairs.

We build boilers of all kinds for any service. We are also sole Canadian manufacturers of the Erie City Water Tube Boilers. Absolute satisfaction guaranteed.

Write us for prices and specifications.
